Bleibtren replies to his critics, Eykman and Hamburger, in a later issue of *Pflüger's Arch.*, p. 405, acknowledging that his method estimates the volume of the corpuscles too low on account of the fact that the 0.6 per cent. solution of common salt is not isotonic with the plasma. But changing to isotonic dilutions, he claims that his method will be found of great service. He no longer sustains his former unconditional condemnation of the centrifugal method, although he still believes that even in the most favorable cases it will not give the actual volume of the blood-corpuscles, but only a proportionate amount. On account of the varying sizes of the corpuscles in pathologic blood, we can not expect absolutely correct proportions between the actual and the estimated volume, and differences will probably be found similar to those noted between the blood of different animals.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, FEBRUARY 8, 1896.

THE ATLANTA MEETING.

As usual, the JOURNAL of the Association will manage an official train from Chicago to Atlanta direct without change of cars. Every convenience will be furnished, and it is expected that the train will leave Chicago on Sunday afternoon, May 3, arriving in Atlanta Monday at 4 P. M. We hope all of our members from the West and Northwest who desire to attend the meeting, will make arrangements to concentrate on JOURNAL train at Chicago. The President, Trustees and several members of the Business Committee will be on this train. The Secretary of the Association, Dr. ATKINSON, has already made application to the various railroads for the usual reduction in rate of fare, which will be applicable all over the United States. The large increase in membership of the Association should make this an easy task for the permanent secretary.

Section officers will facilitate the preparation of the program by forwarding titles of papers to the JOURNAL as fast as received.

THE HYGIENE OF WAR.

Under the heading, "The Hygiene of War," the *Lancet* (London, England) in a recent issue refers to a work undertaken by Dr. PAUL MYRDACZ, staff surgeon-major of the Austrian army, which bids fair to supply reliable data to all persons interested in military vital statistics with reference to active service. Two fasciculi of his work have been issued, one giving the history and present state of the French sani-

tary service and the other the medical history of the Crimean war; but Dr. MYRDACZ intends to embody in his work a description of the health departments of the principal armies of Europe, a medico-chirurgical history of recent wars, the effects produced by modern projectiles and a general review of improvised hospitalization and transport. According to the *Lancet*, medical officers of the Austrian army are obliged to satisfy examiners regarding their knowledge of the Crimean campaign, with especial reference to sanitary matters, before they can be promoted, and it was in order to act as a text-book for this ordeal that this historical fasciculus was originally written. It contains a complete *resume* of the chief events of the memorable siege of Sebastopol. Details concerning the military operations are given side by side with a full account of medical and sanitary procedure, the whole forming an animated recital of a most important campaign.

So far as regards the organization of the hospital departments of the great armies of the world we have already been informed fully by MAJOR J. VAN R. HOFF, U. S. A., in his excellent paper on the subject read at the last meeting of the Association of Military Surgeons of the United States, and recently published in pamphlet form. MAJOR HOFF with laudable patriotism includes the Army of the United States in his paper, although its present numerical strength is nearly equaled by that of the garrison of more than one European city. He is justified, however, when we consider what the Army of the United States has been and what it would be if the exigencies of the times called for the military strength of the States to assemble under the National flag. After describing the present status of the medical department and hospital corps, he comments on the fact that we have no detailed scheme of organization for active service. "Contrasted with the almost perfect sanitary organization of other armies, our own unpreparedness in this direction points a moral we can ill afford to ignore."

The new Army Regulations under the heading "Field Service" has only four short paragraphs in relation to the work of the Medical Department, and in none of these is there the slightest suggestion of organization on the grand scale. The Regulations of 1889 contained an outline of the methods to be adopted in war service and for the care of the wounded on the battle-field; but this has been omitted from the new edition, probably to be embodied in the Regulations for the Medical Department to which it properly belongs. It is understood that the manuscript of these latter regulations, prepared by SURGEON GENERAL STERNBERG, has been approved by the SECRETARY OF WAR and will be published in a short time. It is unlikely, however, that they will enter into the details of hospital organizations such as are

to be found in the existing status of the medical departments of the large armies of Europe. We do not require to have our small army organized by brigades divisions and army corps. It is scattered in small commands at military posts from the Atlantic to the Pacific. Nor do we require to have our medical officers and hospital corps detachments organized for attachment to skeleton or possible brigades and divisions. They are at present as scattered as is the Army. But just as our military men keep always in view the possibility of war, as the *raison d'être* of our military establishment, and familiarize themselves with all the methods by which an organization for war may be built up on our standing army as a nucleus, so our medical and other staff corps have always in view the same possibility and the necessity for their expansion under a call for war service. MAJOR HOFF's paper is itself an illustration of this on the part of an army medical officer, and the existence of the Association of Military Surgeons before which the paper was read manifests a full appreciation of the subject on the part of the medical officers of the military forces of the States. We do not, therefore, coincide with MAJOR HOFF in his view that our condition in this regard is one of unpreparedness; for should the emergency arise we feel confident that under the present able administration of the Army Medical Corps the expansion of the Department would go on *pari passu* with the aggregation and consolidation of the troops mustered into service under the call of the PRESIDENT for an armed force, and that by the time we had brigades, divisions and corps to go into battle we would have brigade, division and corps ambulance organizations to care for their wounded.

MEDICAL MAKESHIFTS.

The advocates of higher medicine have no more serious duty than to impress upon the members of the medical guild, especially upon the men of the future, the necessity for maintaining and asserting the dignity of their profession, the importance of its labors to the welfare of the body politic, as well as to the health and vigor of individual bodies physical, and the pecuniary value of its services to the State, compared with those rendered by divines, jurists, legislators and executive officials.

The eleemosynary relations, which practitioners ungrudgingly assume because of the dominant humanitarianism of their calling, have, in fact, operated to belittle their occupation. When the terrifying shadow of death has been dissipated, the skill of the doctor, who has caused the house of mourning to become one of rejoicing, is forgotten. Equivalent remuneration is seldom tendered, and if after long waiting a charge is presented it is apt to be questioned, though it be rarely proportionate to the value of the life

saved. Where the attorney receives thousands of dollars, not one physician in a multitude can expect hundreds, and the retainer of the counselor in advance of his services, has no parallel with the physician undertaking a new case. The recent decision of a St. Louis court sustaining a surgeon's charge of \$5,000 for a trephining operation, is a notable exception in medical experience, as was the honest declaration of the learned judge that he allowed the bill, "not simply because the financial condition of the defendant was such as to allow so large a bill to be paid without serious inconvenience, but on account of the character of the operation, which of itself was well worth the fee demanded," but would even this judge have admitted that the successful management of a case of typhoid fever implied quite as much knowledge, skill and judgment, and was entitled to a similar compensation? The instance is still recent where a well-known millionaire contested a smaller fee than this in a case involving risk to life, at the very time he had given a famous lawyer, without objection, a retainer of \$10,000 in a mere question of property.

It is this ignorance of the weighty value of physicians' services, and the diffidence of the latter in asserting it, as well as their tacit acquiescence in the popular estimate of that of which the public is not competent to judge, that has led to makeshift methods in all matters medical in municipal and national administration. COL. WARING, the Commissioner of Street Cleaning of the city of New York, deserves commendation, not alone for the excellence of the service he has instituted as for his fearless valuation of it. He has done the work as it should be done, and not upon the miserable makeshift principle of making the money available go as far as it could. State Boards of Health have demonstrated their value to their several communities, but not one of them is bold enough to insist upon the really necessary provision of means by State legislatures, and they do their work as best they can with what is given them. An epidemic is averted, the loss of millions through trade paralysis is prevented, thousands of lives of wage earners are saved, but not one of the members of these health boards receives anything but a pitiable salary, if paid at all, and the expenditures of the board have to be itemized to unit dollars and fractional cents. A million or more dollars are voted for a battle-ship; would a million be appropriated as promptly to defend the country against such an enemy as yellow-fever, which can slay more victims in less time than powder and shot, paralyze trade more effectually than a blockading squadron, and retard progress more seriously than the occupation of a city by a beleaguering army? There is no National Department of Health in this country—absolutely necessary as it is admitted to be—because of the prevailing makeshift spirit, which induces the people to

get along without one, and thus save its cost, for costly it need must be, if it be what it should.

Another illustration of the motive of this article is to be found in the recent report of the Surgeon General of the Navy, who in explaining the impossibility of filling the vacancies of the medical corps, says: "The law does not provide for the temporary appointment of acting assistant surgeons to meet the emergency that has arisen," and it is fortunate that these makeshift appointments are not permitted. The emergency referred to is simply an existing necessity for the full complement of medical officers, authorized by statute, and therefore not a mere temporary emergency at all, but a persistent, urgent deficiency in the organization of a department of the government due to the failure to provide the requisite number of officers, for causes easily remedied by legislation, and there is no reason why recourse should be had to makeshifts in the shape of acting assistant surgeons, who are not required to pass the examinations for admission, which are presumably merely the measure of ability to do the duty required, but who, notwithstanding their inability to pass these examinations, are nevertheless, expected to perform this duty. Naturally, the same thing will occur as when the acting assistant surgeons, who having served throughout the civil war, interchangeably with regular officers, applied, as they were justified in doing, by reason of long, faithful, and satisfactory service, to be admitted to the permanent class, although they had never fulfilled the preliminary requirements.

While there is in fact, no excuse for makeshifts in any branch of the national service, they have not been less uncommon in the Army than in the Navy. Not long ago, a cavalry officer, relieved from duty at an Army Recruiting Rendezvous, was narrating his experience during his term of service and stated in reply to the inquiry as to who was the medical examiner associated with him, that there was none, and upon a physician expressing astonishment that expert professional duty of this important character should be exacted of him, said that this was not unusual. "I held Tripler's manual open in one hand, while I followed it as best I could," he added. "But do you know how to auscult?" and after the nature of the operation was explained to him, he replied, "Oh! I put my ear down and if I did not hear anything particularly alarming I passed the man!" When it is remembered that the recognition of visual, pulmonary and cardiac defects is the most difficult of the medical examiner's professional work, it is not surprising that this cavalry examiner admitted that a great many of his recruits were subsequently found unfit for service. Every such improper enlistment, involving discharge for disability existing at the time of enlistment is a matter of indefensible expense to the government, besides impairing discipline and efficiency if the phy-

sically defective recruit is retained to avoid the loss of pay, clothing and transportation. Nothing can justify the makeshift principle which requires an incompetent individual to discharge duties for which a sufficient number of qualified officers ought to be provided; nor is there any excuse for employing army hospital stewards or naval apothecaries in the rôle of medical officers, whether as physical examiners, considered the most delicate and responsible of military and naval medical officers' duties, or as prescribers and care-takers in cases of disease or injury, when the possibility of fatal consequences or of permanent impairment should preclude their ever handling scalpel or hypodermic syringe. Whether it be two hundred or three hundred or more thoroughly qualified medical officers who are required for the proper performance of these duties, they should be obtained at whatever cost, and no pretense of economy can ever justify their substitution in a single instance or under any circumstances, by incompetent makeshifts.

THE INFLUENCE OF PUBLISHERS UPON MEDICAL LANGUAGE AND LITERATURE.

Neither the lay or the professional public has any adequate understanding of the methods whereby, and of the extent to which, publishing houses are influencing opinion, and of all the motives at work. An illustration of the fact lately came to our notice, that throws quite a vivid light upon the ways of book-makers. A certain lay dictionary of the English language having an extensive sale especially in some parts of the United States, throws the weight of its authority in favor of certain methods of spelling words. A rival publishing house proceeds to hire a corps of "expert" philologists to re-edit its own rival dictionary, and instructs said philologists to spell all disputed words differently from the competing book, if for such difference of orthography there can be found any sort of a decent excuse. The smile that wreathed the face of the lexicographic editor as he told this "plain unvarnished tale," also expressed clearly enough the fact that philology, good taste and general usage, had been thrown, like physic (or physick), to the dogs, and that commercialism was the sole motive in continuing useless word-wrangling. The silly public would feel compelled to buy both books in order to justify its hodge-podge of linguistic customs. At this rate, it is plain that every publishing house will, in time, have its authoritative lexicon, and every "disputed word" may have as many forms and varying definitions as there are enterprising publishing houses.

But the Babel-makers do not stop here. Each publishing house must abide by its own "standard," and so all books and periodicals published by the firm are cut and clipped to fit the Procrustean bed established by the dictionary published by that firm,

regardless of authors' rights and wishes, regardless of the original from which reprints and subsequent editions may have sprung. It thus becomes evident that the formation of dialects and new languages is not to be ended by the supposedly sufficient influence of intercommunication and the printing press. The establishing of a dominant tongue may thus turn out to be dependent upon the commercial supremacy of the publisher who prints the most books and that pushes his own dictionary into the most general use.

Now in medicine we are actually enduring or fast coming to something very like this. A medical publisher that has published a medical dictionary makes that the rule of the printer's office regardless of all other considerations. All its books and periodicals are put out with spellings, etc., guaranteed as correct by the special authority, entirely oblivious of philologic principles, of common usage, or of desirable reforms. Each thus pursuing his own orthographico-financial way, confusion is growing fast and furiously worse confounded. The poor proof-reader or typesetter, if he change his employer, is constrained to unlearn a thousand rules that held across the street or in a neighboring city, and learn anew what the particular authority demands that has been chosen by the firm—and chosen because "we must uphold our own dictionary sure!"

Thus is born the bastard of opposition to all progress in medical language. That such progress is extremely desirable, nay, absolutely necessary and inevitable, no dispassionate observer would deny. That such cunning trickery of publishing houses can finally and entirely prevent betterment and shortening of the language is absurd. All they can do is to delay and make reform more difficult. Come it will despite the most stupid conservatism and the most selfish commercialism. Americans will be as likely to spell center and literas Frenchmen do, as likely to stick the *u* back into *color* or *favor*, or the *x* into *hemorrhage*, *ether*, or *gangrene*, as they will be to give up Pullman cars for old stage-coaches, or to dress once more in stocks and stoles.

But, as says the old saw, we have yet the tail to skin. The ingenuity of the schemer is not exhausted. There is left the commercial medical college, its "List of Books Recommended" and the special professorial commendation of a certain text-book. The diploma-mills are fast becoming annexes of the publishing business. The only limit set, happily, by the very nature of things, is the effective one of competition. A traveler tells how in waiting for game on a Scotch moor, he told his gillie all about the wonders of American civilization, its Niagara, its twenty-five story buildings, telegraphs, phonographs, wizards and billionaires, receiving from his listless listener no glance or word of interest, no slightest sign of wonder. Finally in despair he asked Jamie what he

thought of these things. "Aweel, mon," said the pawky doubter, "ye should know I'm something of a liar mysel'." A fortunate barrier against medical text-book monopoly is assured by the fact that each great man has his own best text-book on the subject; or, if not, he has at least his own little private jealousy and rivalry to spur him to say, "Thus far and no farther!" In this way, as so often, we find, "there is some soul of goodness in things evil."

And the books, such books! as have been issued from the press during the past twenty years! When conceit, ignorance and avarice come to the judgment bar for their rewards, the heavenly bank will certainly be soon bankrupt!

THE MEDICAL PEDAGOGY OF CHICAGO.

In connection with the editorial summary on medical education in a late issue of this JOURNAL, it is interesting to note that the *Cook County Medical Announcement*, "a quarterly periodical of local medical information," is in its latest issue a directory of Chicago physicians engaged in medical education at the present time. These number 590, or just about one-sixth of the total (estimated) number of medical practitioners in the city. The list, however, does not profess to include any of the physicians connected with the schools who have not regular or definite appointments, and therefore may be considered as an under, rather than an over, statement of the total of medical teachers, and we can assume legitimately that over one-sixth of Chicago's medical population are of a sufficiently high grade to be professors or instructors in one or the other of the thirteen or fourteen different institutions of medical learning. The list also gives other interesting data than merely the enumeration; it shows that quite a respectable minority are pluralists, so to speak, holding positions in more than one faculty, and there is one instance, at least, where the same individual is given as at once a professor in four different institutions, representing the regular, homeopathic and eclectic schools of practice. The lion has evidently lain down with the lamb and the medical millenium must be close at hand.

There are other curious facts to be found in this list, suggestive of still more curious reflections. The most impressive one of them all, however, is that if the profession of medicine is not overdone in this country, if there is not already a larger proportion of doctors than the population can support and the ratio disastrously on the increase, it is not through any fault of a very considerable and eminently respectable minority of the medical practitioners of the great city of Chicago, who are presumably doing their best to increase and multiply the full-fledged members of our honored profession. So large a plant should have a correspondingly magnificent product.

Speaking seriously, however, these figures naturally bring out the question: What is the value to the profession and to the world of this multiplication of institutions of medical instruction? Why should there be five regular undergraduate medical schools in Chicago to say nothing of "homeopathic" and other irregular institutions? There is no need to give the answers to the questions; they will suggest themselves to any well informed physician.

An honorable rivalry between two, or, at most, three well established and equipped medical colleges in the same medical center is in its way a good thing, if the efforts are only directed to improving the quality of the instruction without too much reference to the quantity of doctors turned out on the world and the corresponding increase of fees. But any very extensive competition makes true the business adage about its being the life of trade and may in the long run tend to the disadvantage of the profession as a whole, whatever benefits may accrue to the few, or, perhaps, under the circumstances, to the many who receive the advertisement as professors in a medical faculty. The dispensary evil, in regard to which so much has been said, may yet come to have its counterpart in the medical college evil, alike, though perhaps not equally, detrimental to the best interests of the medical profession.

It would be of interest had we the similar figures for other medical centers, New York, Philadelphia and St. Louis, to compare them with those given for Chicago, and to fully round out the compilation of evidences of medical educational zeal we ought also to include the data of physio-medical, vitapathic, Christian science and other so-called medical schools that flourish and are recognized as such by a gullible public.

THE TRUE AIM OF SICK-ROOM DISINFECTION.

The *London Lancet* has attempted an analysis of the latest improvements for the practical disinfection of living rooms. In its editorial columns it is remarked that the frequency with which second and third case of scarlet fever or "recurrences" appear in houses that have been disinfected by the inspectors of sanitary authorities, casts grave doubts on the efficacy of procedure usually adopted, despite its official sanction. Stripping the walls, lime-washing walls and ceilings and scrubbing woodwork and floor boards with soap and water are indeed effectual enough, and to these when thoroughly done we are disposed to ascribe any successful results rather than to the more technical process of so-called disinfection by sulphur fumes, which is little better than a superstitious rite or incantation shorn of the religious character it had in the mind of ULYSSES when he "fumigated" the halls desecrated by the massacre of his wife's suitors, after removing the

corpses and washing away the blood with a promptness that precluded all thought of other than moral pollution. But in the light of bacteriologic experiments dry sulphurous acid fumes, whether generated by burning sulphur or carbonic acid sulphid, or, as has of late become the fashion, by opening cylinders of the compressed gas, are for all practical purposes useless. The gas would act as a powerful germicide on articles of fabrics previously saturated with water, but its bleaching action precludes its employment in this way with colored material, carpets or curtains, and it is as what is called an "aerial disinfectant" that it holds its ground in popular esteem. But aerial disinfection is an absurdity; no one wants to purify the foul air, which is easily enough removed by simple ventilation. In disinfecting a room the true aim is to kill the germs contained in dust on ledges or in the crevices between the boards, or adhering to the walls and other surfaces, and the dry gas is powerless to do this, which is best obtained by a sublimate solution of the strength of one part in 1,000, or by lime- (not white-) washing, providing the lime be freshly burnt and caustic; the carbonate of lime, or chalk, used in white-washing under the name of whitening, and into which lime is converted by long exposure to the air, being inert. The series of experiments on the infection and disinfection by various means, of wall paper, distempers, and other wall surfaces conducted by DR. KRONBERG, under the direction of the late PROF. UFFELMANN, at Rostock, showed that subsequent scraping were invariably and almost instantaneously sterilized by washing or spraying with the sublimate solution, and equally so by the lime-wash after the lapse of twelve or twenty-four hours. *The danger of corrosive sublimate is we believe exaggerated*; since the smallest fatal dose for an adult being probably three to five grains—equal to at least a quarter of a pint of the solution—accidental poisoning with the solution is practically not probable, and as a further safeguard it might be colored with indigo or "laundry blue." Carbolic acid, which is sold without restraint and is in universal use, is more dangerous on that account, and is, indeed, frequently employed with suicidal intent and with fatal effects. In France, Germany and Italy sublimate has nearly superseded all other disinfectants, and its neglect in this country is inexplicable. As to carpets, bedding and clothing, all that is capable of being washed should be plunged into a copper of boiling water for a quarter of an hour, and such articles as would be spoiled by this treatment should be disinfected by steam.

This point in reference to the powers of sulphurous acid gas, whether dry or moist, will in the future, we think, receive a fuller consideration than it has had in the past, namely, that it leads to a prolonged aeration on the part of the occupant after the officials have left the premises. Here we have an aerial disinfectant that is a clear gain, supplementary and complementary to the routine work of the disinfecting staff.

CORRESPONDENCE.

Treatment of Nasal Duct Obstruction.

CHICAGO, Feb. 3, 1896.

To the Editor: If I may be permitted to add a few words to Dr. Wandless' letter on this subject I would say that the statement of Dr. Taylor, regarding the frequent failure of probing for the cure of stricture of the soft parts, is largely borne out by the facts. As practiced by the average ophthalmic surgeon the use of probes accomplishes very little toward relieving the lachrymation and other annoying symptoms. Indeed, stricture of the naso-lachrymal duct has long been one of the opprobria of eye surgery and when one considers the pathology of this condition we have at once an explanation of such an unsatisfactory state of affairs. Suppose the general surgeon were to rest content with an internal urethrotomy in these cases which, pathologically, closely resemble the simple form of nasal duct obstruction: what would be the probable result six months afterward? About as much as is accomplished by merely incising the cicatricial band that usually constitutes ordinary obstruction in the duct!

If Dr. Wandless' program could be followed in all cases a cure would doubtless result, because if there is one thing that is established in these cases it is the necessity of faithfully using as large a probe as possible for months and even for years at a time. Cutting through the stricture combined with the irregular or occasional use of a small probe, not only accomplishes nothing but such a procedure makes the latter state of the patient worse than the first and discourages him from undergoing further treatment. He wanders over the country deriding ophthalmology in general and his late oculist in particular.

Whatever Texan patients may do my experience of Northern sufferers is that they soon tire of coming to one's office for months, even at increasing intervals. *Teach them, then, to do their own probing* and have them thoroughly understand that their ultimate cure lies entirely in their own hands. Use large, aseptic probes and disinfectant collyria and in two weeks after the preliminary operation the patient may be dismissed, having in the meantime, been taught how and when to probe his (more often *her*) own duct. My experience is that all patients, even the most nervous women, learn to do this easily—often better than the oculist himself.

CASEY A. WOOD, M.D.

An Inquiry Concerning the best Climate and Waters for Bright's Disease.

CAMDEN, N. J., Jan. 26, 1896.

To the Editor: Can you advise me what location and climate, in this country, offer, in your judgment, the most hope for a person afflicted with incipient Bright's disease to visit? Any answer, on inquiry through THE JOURNAL, you may be good enough to make will be appreciated by

Yours truly,

E. L. B. GODFREY, M.D.

From a Retired Member.

NEWPORT, N. H., Jan. 28, 1896.

To the Editor: Your letter with sample copy of the JOURNAL are received. Many thanks for the remembrance. In the success of the AMERICAN MEDICAL ASSOCIATION and its publications I have felt a deep interest from the time of its organization in 1847. I have most of the annual reports and *all* the volumes of the JOURNAL until July, 1891. During a severe and protracted sickness that spring and summer, through some misunderstanding, my membership fee was not sent and my name, as it was right it should be, was dropped from the subscription list. As delegate from our State society I attended the annual meeting in New York in 1864 and in San Francisco in 1871, and as a permanent member, in Boston and Washington, always

finding the occasions full of pleasure, instruction and benefit. My interest in medical literature and science, and in the power, influence, strength, honor and usefulness of our noble profession remains unabated, notwithstanding I am within less than three weeks of my eighty-sixth birthday, an hour too late in life's evening to warrant a renewal of membership.

Most respectfully yours,

J. L. SWETT.

Opinions of The Journal.

99 BROADWAY, SOUTH BOSTON, MASS., Jan. 31, 1896.

To the Editor:—Thank you for the beautiful plates you had provided for my article on splinting.

The JOURNAL under your management has become of medical journals in America *facile princeps*. The matter published during the year is considerably in advance of that in the textbooks, and the typographic dressing you give it is worthy of the matter. I congratulate you on your excellent work since editing the JOURNAL, and hope the JOURNAL shall enjoy your services until it attains the circulation it deserves—20,000—and indefinitely after that.

Very sincerely,

EDWARD A. TRACY.

I have thought for some weeks that I would write you and express my pleasure and appreciation of the way in which you have conducted the JOURNAL. It now stands clearly at the front, and I have only to say, God bless you.

HENRY D. HOLTON, M.D.

Brattleboro, Vt.

ASSOCIATION NEWS.

Atlanta Physicians Preparing for the Meeting.—There will be an important meeting of the regular physicians of Atlanta at the Young Men's Christian Association hall to-morrow night at 7:30 P.M. It will be under the auspices of the Atlanta Medical Society, but all regular physicians, whether or not they are members of the society, are invited to be present.

The AMERICAN MEDICAL ASSOCIATION will hold its annual meeting here in May and the meeting will be held to take the first steps toward the entertainment of the convention. Dr. Beverly Cole, of California, is president of the AMERICAN ASSOCIATION and the most distinguished doctors of the country are to be found in its ranks and will be here at the meeting.

It is expected that there will be about fifteen hundred doctors here when the meeting is called to order. The physicians of Atlanta are determined that the distinguished visitors shall be given the best entertainment possible while they are here.

Dr. Willis Westmoreland, of Atlanta, is chairman of the committee of arrangements, and he is taking an active interest in the coming meeting. *Atlanta Journal*, January 20.

NECROLOGY.

MARCEUS L. TAYLOR, M.D., a resident of Booneville, Miss., died on the 25th ult., at Philadelphia in the Hospital of the University of Pennsylvania. Dr. Taylor was born about 1850. For nineteen years he was connected with the United States Army. While stationed at Jefferson Barracks he was notified of the serious illness of an old friend. He started out on horseback for a long journey of 170 miles in the midst of a blizzard. He reached his destination safely and accomplished his purpose, but was never well afterward, owing to the exposure during the ride. He had decided to practice medicine in Philadelphia and came here for this purpose, but he was obliged to seek hospital treatment soon after his arrival. His death was due to malaria and asthma. He leaves a widow. His body was sent to Booneville for interment.

EDWARD H. TINEN, M.D., of typhoid fever, at Chicago, January 28, aged 22.—George F. Magoun, M.D., of Grinnell Iowa, January 30.—Henry Ladd, M.D., of Melmore, Ohio, January 30, aged 83.—J. P. Gruwell, M.D., of Alliance, Ohio, January 20, aged 85.—Felix P. Callahan, M.D., of Peoria, Ill., January 29.—A. L. Harris, M.D., of Atlanta, Ga., January 28.—J. W. Pugh, M.D., of Stockton, Cal., January 24, aged 78.—John Healy, M.D., of Raywick, Ky., January 28, aged 60.—M. L. Stafford, M.D., of Luray, Mo., January 26, aged 45.—J. M. Waldron, of Porter, Mich., February 1, aged 36.—John R. Meachem, M.D., of Racine, Wis., February 1, aged 72.—Thomas Burgess, M.D., of Nashville, Tenn., January 30, aged 69.—P. P. Whitesell, M.D., of Noblesville, Ind., January 28, aged 73.

THE LATE DR. BASIL NORRIS—Your committee respectfully submit the following expression of respect, and resolutions in memory of the late Dr. Basil Norris:

He who acquires the knowledge of preserving health, obviating disease or death and exerting himself to do good to all men, deserves the homage of his fellow-creatures while living, and when he has passed away he should be held in pleasant and appreciative memory by all who have known him. Dr. Norris, we are gratified to know, received a very large share of esteem and honor, and that we, the members of this Society, of which he was an honorary member, do record the fact that we sincerely cherish the memory of our departed friend and brother.

Dr. Norris was born in Montgomery County, Maryland, March 9, 1828. He was graduated at the University of Maryland in 1849, and entered the United States Army in 1852. He served with troops in Texas, Utah and New Mexico until 1862. He was then promoted Surgeon, and in 1863 was appointed Medical Director of one of the grand divisions of the Army of the Potomac. For meritorious service he was raised to the rank of Lieutenant-Colonel, and finally Colonel. When retired, he was Medical Director of the division of the Pacific. His writings are said to have been numerous and scholarly. He was a genial man, an accomplished physician and efficient officer. He died in San Francisco, Nov. 11, 1895.

WHEREAS, Our professional brother, Dr. Basil Norris, who after a successful career, has been removed by an All-wise Providence, therefore,

Resolved, That as an earnest friend and co-worker his death is sincerely felt by this Society; and that to his relatives and friends we tender our sympathy and condolence;

Resolved, That a copy of this memoir be transmitted to the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and the medical journals of this State, accompanied by the request that it be published.

G. W. DAVIS, M.D.,

BOOK NOTICES.

Twentieth Century Practice. An International Encyclopedia of Modern Medical Science, by Leading Authorities of Europe and America. Edited by THOMAS L. STEDMAN, M.D., New York City. In Twenty Volumes. Volume VI. "Diseases of the Respiratory Organs." New York: William Wood & Company. 1895.

This volume is accompanied by a note from the publishers which states that "owing to unforeseen difficulties in the preparation of volume V, it has been necessary to issue volume VI out of its natural order. Volume V will be the next volume to appear." The contents of this volume include the following articles: 1, "On Diseases of the Nose," by Prosser James, of London; 2, "Diseases of the Accessory Sinuses of the Nose," by Jonathan Wright, of Brooklyn; 3, "Diseases of the Naso-pharynx and Pharynx," by E. J. Moure, of Bordeaux; 4, "Diseases of the Ear," by Albert H. Buck, of New York; 5, "Diseases of the Tonsils," by E. J. Moure, of Bordeaux; 6, "Diseases of the Larynx," by Francke H. Bosworth, of New York; 7, "Diseases of the Trachea and Bronchial Tubes," by Sir Thomas Grainger Stewart and

George Alexander Gibson; 8, "Diseases of the Lungs (Excluding Croupous Pneumonia and Tuberculosis)," by Winslow Anderson, of San Francisco.

The names of the authors are so well known and authoritative, that one knows instinctively that the subjects respectively assigned them will be properly treated. An important statement is made by Moure, p. 289, where in speaking of the antitoxin treatment of diphtheria he says the period of immunity "conferred by the antitoxin has not been determined, but would appear to be about two or three months."

The publishers have illustrated the work well, and its appearance is uniform with the preceding volumes. We can truthfully award this volume the same high praise that was given its predecessors in the series.

An Atlas of the Normal and Pathological Nervous Systems. Together with a Sketch of the Anatomy, Pathology and Therapy of the Same. By DR. CHRISTFRIED JAKOB, with an introduction by PROF. DR. A. D. STRUEMPPELL. Translated and edited (authorized) by JOSEPH COLLINS, M.D. 8vo, cl., pp. 230. New York: William Wood & Company. 1896.

This is No. 2 of Wood's Medical hand atlases, and has 221 figures on 78 plates, three of them folding charts. To the anatomist, the physiologist, the clinician, and as well the general practitioner, who desires to comprehend the clinical picture as seen at the bedside, this atlas will be invaluable. It gives the relationships in a clear and lucid manner, and as stated in the prefatory note: "The student as well as the practical physician who wishes to keep in touch with the advance which medical science has made, from the standpoint of the neurologist, is given the opportunity to get a clear conception of it by means of this atlas."

Pictorial Atlas of Skin Diseases and Syphilitic Affections, in Photo-lithochromes from Models in the Museum of the St. Louis Hospital, Paris, with explanatory woodcuts and text, by ERNEST BESNIER, A. FOURNIER, TENNESON, HALLOPEAU and DU CASTEL, Physicians to Hôpital St. Louis, with the Coöperation of Henri Feulard, Curator of the Museum, and the Secretary, Léon Jacquet. Edited and annotated by J. J. PRINGLE, M.B., F.R.C.P. Part I. London: F. J. Rebman; Philadelphia: W. B. Saunders, 1895. To be published in twelve parts, at \$3 a part.

The Hôpital St. Louis was founded by Henry IV and opened for patients in 1602. It is therefore next to the oldest hospital in Paris, and for the past fifty years has treated about 8,000 patients annually. The museum has been famous for its extensive dermatology and syphilography collections, and now we have these treasures spread before the world, so that all may see color reproductions of this great museum, representing cases actually treated. The plates have an explanatory text by the staff of the St. Louis Hospital, and the names of Besnier and Fournier are alone sufficient to give tone and character to the work. The translation by Dr. Pringle and the typography are worthy of all praise.

The Medical Muse, Grave and Gay. A Collection of Rhymes up to date, by the Doctor, for the Doctor, and against the Doctor. Collected and arranged by JOHN F. B. LILLARD. Cl., pp. 141. New York: I. E. Booth. 1896.

This collection has some excellent and some very poor selections, but the reader having paid his money may take his choice. We miss some of the earlier medical rhymsters such as Armstrong and Fessenden, and there is no attempt to invade the Continent and make any translations from Volkman, or from the French. We miss that characteristic poem of Dr. Holmes entitled "Rip Van Winkle, Jr., M.D.," with which he delighted the Massachusetts Medical Society some years ago, and there are many omissions of more recent American productions. However, the idea of the collection is a good one, and this book, which we hope may reach its second edition soon, is well started, although there are some that might well be spared. We expect to see the second edition twice as large. There are a number of good things in the old *Flos Medicinæ* that might

well be included in the next edition, either in the original or from some of the innumerable metrical translations, one of the best being that of Ordonaux, of Albany. Some of Dr. Holland's (Timothy Titecomb) rhymes are well worthy of being included in such a collection, and we sincerely hope that the compiler, for the credit of American medicine, may next time issue a really representative volume of medical poems, for which this too miscellaneous collection only stimulates the desire.

Medical Jurisprudence, Forensic Medicine and Toxicology. By R. A. WITTHAUS, A.M., M.D., and TRACY C. BECKER, A.B., LL.B., and a staff of collaborators. In four royal octavo volumes. Volume III, pp. 697. Forensic Medicine (continued). New York: William Wood & Company. 1896.

In this volume the subject of forensic medicine is continued, and the contents are as follows: 1. "Vision and Audition in their Medico-legal Relations," by J. H. Woodward, M.D.; 2. "Medico-legal Aspect of Insurance," by D. Murray, Esq., and G. J. Edwards, Esq.; 3. "Insanity in its Relations to Medical Jurisprudence," by E. D. Fisher, M.D.; 4. "Mental Unsoundness in its Legal Relations," by T. C. Becker, Esq.; 5. "Care and Custody of Incompetent Persons," by Goodwin Brown, Esq.; 6. table of cases cited in the volume.

The topics, as will be seen by the synopsis, are important to physicians in their capacity as experts, to alienists, lawyers and as well to practicing physicians. The statutory requirements of all the States of the Union are given in regard to the commitment of the insane, and to their care and custody. This volume is a worthy companion to its excellent predecessors.

The Old Virginia Doctor.

Dr. John Herbert Claiborne, an ex-president of the Medical Society of Virginia, has sent us a brochure, bearing the above title, and having for its object an embalming of the memory of the medical profession of the Old Dominion as it existed in the post-Revolutionary period. As Dr. Claiborne set his mind upon the study of medicine fully fifty years ago—he was graduated in 1849—he must have been personally cognizant of some of the survivors of the class of which he writes, and writes most feelingly. He says of the medical aspirant of those early days, that there was little chance for poor men's sons in Virginia's medical fold, the expenses of preparation were so heavy.

"The medical student had to hold the sinews of war from the inception of his career. And he was usually the scion of a house in which years of entailed wealth had given leisure, and leisure culture, and culture preëminence. He was the son of a gentleman. He was a gentleman himself; and he never forgot it. He was of kind and gracious dignity to his fellows, more kind and gracious to his inferiors, never knew any superiors, magnified his noble life, and if he ever let himself down, it was only semi occasionally, with the old boys, of which his compeer, the old Virginia lawyer, was generally one.

"There were two of him—the old Virginia doctor: the town and the country doctor. But there was not the difference, real or supposititious, between them, as exists now between these same representatives of the same profession. The town was small, and the country large. The town doctor extended his practice far into the country, and his clientele often brought him into the circuit of his country brother. And he recognized him as a brother. Had they not both been students under the same master? Had they not been apprentices perhaps in the same surgery or shop? And had they not read the same books? And did they not both use, and equally as well, the same instruments? The former assumed no airs, and put on no pretense of superior skill, or greater wisdom than his country comrade. They met one another on the same plane of honest and sturdy fight with disease and death, and were both well and equally equipped for the contest with the common enemy, and carried with their armamentaria a sound sense and a sagacious judgment, that shrank from no call and failed in no emergency. Nor did they divide amongst them-

selves the human members, and assign to separate care the eye, the nose, the head, the scrotum and umbilicus. He was no specialist, but swift as the mythologic Mercury, whose device he bore upon his staff, and strong of heart as Ajax, asking nothing but light, he went to heal and to save.

"There was only one class that did not love the old doctor—to them he was a terror, viz: the children of the family and plantation. To the white children he was the author and director of all the calomel, and rhubarb, and jalap, and oil that was given them when sick, and administered not by persuasion or promise of reward, but forced down their throats by threats of bringing in the doctor with his lancet and pullikens (tooth-forceps). To the colored children he was something worse. He was a superstition and a fetish. His physics were made of dead men's bones. Mammy had been in his shop once, and had seen a dead man—all bones—hanging up behind the door. And he carried great sharp knives, and the nurse at the 'gret house' said that he had cut off Uncle Tony's leg when the mule ran away and broke it.

"But the climax came with his visit to vaccinate everybody. During the first quarter of the present century, Jenner's immortal discovery that a prior attack of cowpox rendered the human subject immune to smallpox, had just been accepted in all its import and promise. And edict followed edict, from plantation to plantation, that all should be vaccinated. That day was a field day for the old doctor. He himself had had variola by inoculation during his apprenticeship, as was the custom of the day, that he might be protected from contagion in his subsequent practice. But vaccination now was known to be equally efficacious to protect the doctor, and more desirable, as the disease itself might be spread by an inoculated patient.

"As the doctor approached the plantation the children, who had heard of his coming, fled like chickens, and had to be ferreted out from corner, and crevice, and bush, and brought back, '*vi et armis*,' with struggles and screams that made the day a memento of pandemonium. But whoever shrunk from the ordeal, the old doctor never faltered. And when he had planted his mark upon the biceps, time did not efface it. No septennial period demanded a repetition of the process. Not seven years, nor twenty-seven years, nor sixty-seven years have yet effaced it, in the few who have dodged death's javelins so long. In peace and in war, in prison and in hospital, this strong talisman has stood the test of time."

Literary Announcements.

NEW ANATOMIC ATLASES.—The Anatomic Congress held at Bâle the past year voted for a certain nomenclature, and consequently the old atlases are comparatively out of date. Vienna and Leipsic are each publishing now a handsome atlas with the official nomenclature. Both are fine works. The Vienna atlas, by Dr. Toldt, is to contain 1,000 wood engravings, and be published complete in two years. The other, by Dr. Spalteholz, will be finished this year; it is to have 750 auto types in colors and contain a brief description of each plate. The price of each is about the same, 30 marks.

PUBLIC HEALTH.

Typhoid Fever in Mexico. A writer in the *Revista Médica* of Jan. 1, 1896, asserts that typhoid fever is becoming acclimated in the city of Mexico, as a few cases have occurred, all quite mild. It seems that until recently it was never encountered by physicians there.

New York State Board of Health. At a recent meeting of this Board the subject of tuberculosis in cattle was reported upon by the special committee on tuberculosis. According to the *American Medical Review*, January, this committee is expected to report monthly on the cattle tested by tuberculin during the month, giving the number of diseased cattle found and destroyed, together with the amount of awards made to the owners of the condemned animals. The aggressive character of the newly constituted Board is further shown by the fact that the chemist of the Board, Dr. Tucker, was directed to

secure a sample of the illuminating oil used by the Manhattan Elevated Railroads of New York city, for the purpose of ascertaining whether the State law requiring a 300 fire test is being complied with.

Hygiene at the University of Michigan.—The positions of professor of hygiene and dean of the literary department of that institution has been offered to Dr. Eliza M. Mosher, of Brooklyn. This position has never before been held by a woman. Dr. Mosher is a graduate from that University, of the class of 1875, and was for a time a professor of physiology and hygiene at the Vassar College. She is expected to enter upon her duties at Ann Arbor in October next.

Epidemic of Typhoid Fever Among Cavalry Officers.—Following a banquet of the officers at Rennes, France, six were attacked with typhoid fever and two died. The sickness was confined to the lieutenants, who sat at a separate table, although the menu was the same for all. They were the only ones who used champagne frappé, which gave the investigators a clue. They found that the water drained from the ice in the refrigerator into a receptacle below. The ice was obtained from the river flowing through the town into which the sewers drain. The conclusion seems inevitable that the carafes for this table must have been filled with water drained from the ice, to save the attendants the trouble of fetching pure water from the public hydrant outside of the building, and some distance away.—*Bull. Méd.*, Jan. 12, 1896.

The Dangers of "Made Lands" of Cities.—The *Medical Press and Circular*, January 15, contains a summarized report of one of the health officers of an eastern district of London, on the unsanitary conditions of houses that have been built on ash-heaps or filled-in ground.

"The medical officer of health for Hackney has once more called attention to a besetting sin of jerry-built houses. In a lately issued report he pointed out that many of the houses in his district were built upon a layer of house refuse, which in turn rested upon a bed of clay. Such a condition of affairs naturally leads to the drawing into the house of various gases of decomposition and of other components of ground air. This danger has been discussed in our own columns for many years past. That it is a common and fruitful source of disease can scarcely be doubted. In many parts of the suburbs of London it is a constant practice of the enterprising builder to fill up with ash refuse any pit that has been quarried for stone, sand, or other material. He then proceeds to run up a more or less showy villa on this green mass of miscellaneous animal, vegetable and mineral stuff. As a rule, the basement is not provided with an impermeable concrete flooring, so that the house settles, the drains are dislocated, and the inside of the house becomes permeated with poisonous ground air. The remedy is simple. No new house should be occupied until it has been duly inspected and certified as properly constructed by a competent sanitary authority. At present, the remedy which the tenant of an unhealthy dwelling has against his landlord is slow, tedious, and uncertain. The advent of some searching and practical domestic legislation would speedily put an end to the ghoulis race of jerry-builders."

Premature Occupation of New Houses; A Test for Relative Humidity of Habitable Apartments.—The sanitary writer for the European edition of the *Herald* treats of the disadvantages and dangers arising from dampness of the domicile. Regarding newly built houses he says, "Sanitarians, for the most part, teach us that a period of four months in summer and six months in winter ought to be allowed between the end of the building operations and the entrance of the inhabitants in a house. In this way will be avoided the accidents that arise from the premature occupation of an apartment. It is scarcely necessary to add that as soon as the house has begun to be occupied, to avoid dampness, it should be heated and ventilated, treated, in a word, by all the usual means to maintain a healthy condition of the apartment. If the dampness persists in spite of all these precautions, the proprietor is responsible for the defects in his building. Physicians are sometimes requested to estimate the relative dampness of an apartment or room. This is not always

easy by simple inspection, as a room may be damp although saltpetre does not grow on its walls or mold in its corners. The following is an exact means of appreciation and one that is within every one's scope. In the room in question a kilogram of fresh lime should be placed after hermetically closing doors and windows. In twenty-four hours it should be weighed, and if the kilogram has absorbed more than 10 grams of water (that is, more than 1 per cent.), the room should be considered damp and classed as unhealthy. The question of the dampness of dwellings is a frequent cause of dispute between landlord and tenant, naturally solved in the affirmative by the latter, and in the negative by the former. The question can be settled in the future by the test of the hydration of lime, of which I have just spoken, and which will give irrefutable proof or refutation of the validity of such complaint. The dampness of dwellings is a cause of illness. The death rate is greater in quarters where the apartments are damp than where they are dry. Ventilation is defective where the walls are impregnated with water; the porosity of the walls is done away with and can only be reestablished after the evaporation of the water has been completed, and the heat required to effect this evaporation is furnished by the person living in the room. This is the cause of the vivid impression of cold which we experience in damp places, and it is a well known fact that exposure to the action of cold renders the organism more accessible to the attack of morbid germs. The rotting of walls, which appears particularly in places where the water used in building contained nitrates and chlorids, is caused by changes from dryness to dampness and vice versa. It gives rise to fragmentation of the mortar and even of the building stones themselves. Finally, frost can split a wall that is soaked in moisture.

"The dampness of dwellings is due to internal or external causes. There can be no doubt that a new building ought to be treated for a certain length of time by ventilation and heat with a view to evaporating the really enormous amount of water incorporated with the building materials. According to Pettenkofer, a three-story house requiring 167,000 bricks would need some 835,000 liters of water to build. When this evaporation has been effected great care should be taken in insuring proper drainage for rain and other water."

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Indiana: Seymour, January 29, 1 case.
Louisiana: New Orleans, January 18 to 25, 14 cases, 2 deaths.
Michigan: Detroit, January 25 to February 1, 1 death.
West Virginia: Wheeling, year 1895, 14 cases, 2 deaths.

SMALLPOX—FOREIGN.

Dublin, January 11 to 18, 1 death.
Havana, January 16 to 23, 3 deaths.
Odessa, January 4 to 11, 12 cases, 4 deaths.
Prague, January 4 to 11, 5 cases.
Rio de Janeiro, December 21 to 28, 35 deaths.
St. Petersburg, December 28 to January 11, 21 cases, 7 deaths.
Swansea, January 11 to 18, 2 cases.
Tuxpan, January 4 to 11, 3 deaths.
Warsaw, December 28 to January 11, 5 deaths.

CHOLERA—FOREIGN.

Calcutta, December 14 to 21, 35 deaths.
St. Petersburg, December 28 to January 11, 79 cases, 43 deaths.

YELLOW FEVER—FOREIGN.

Havana, January 16 to 23, 5 cases, 2 deaths.
Rio de Janeiro, December 21 to 28, 52 deaths.
Sagua la Grande, January 11 to 18, 5 cases.

Consulate-General of the United States of America.
RIO DE JANEIRO, Dec. 31, 1895.

Sir: I have the honor to remit report for the week ended Dec. 28, 1895.

There were 26 deaths from *Accesso Pernicioso*, an increase of 6; 52 from yellow fever, an increase of 15; 35 from smallpox, a

decrease of 5; 5 from beriberi, an increase of 3, 3 from enteric fever, a decrease of 10; 1 from whooping cough, none in the foregoing week; none from measles, 1 in the foregoing week; and 45 from tuberculosis, a decrease of 10. From all causes there were 423 deaths, an increase of 23.

Yellow Fever. The weather is unusually hot and dry, and with it goes on yellow fever daily increasing. Unless there is some change in the weather, a bad epidemic may appear.

Smallpox. This disease is slowly decreasing, and bids fair to finish soon, but as yet it is epidemic.

Cholera. The cholera scare in Campos is about over, and no cases, not even suspected ones, have occurred here. A telegram in this morning's papers, states that one undoubted case and two suspected ones have appeared in Buenos Ayres.

Respectfully yours,

R. CLEARY, M.D.
Sanitary Inspector, M. H. S.

MISCELLANY.

The "Health University" *redivivus*.—We notice the following in a Chicago paper: "Dutton Medical College, Chicago: incorporators, George Dutton, Sophia B. Dutton and Robert Green."

Correction.—In list of contributors published in the last number of the JOURNAL for preceding year: Dr. Wm. Francis Drewry's address should have been Petersburg, Va., instead of Pittsburg, Pa.

Blaze at Jefferson Medical College. [Special telegram to the JOURNAL, Feb. 4.] During Professor Chapman's lecture, a fire broke out in the chemical laboratory, which seemed to threaten the destruction of the entire building. By the commendable coolness of the students in attendance the flames were extinguished without serious loss.

The Autophakoscopy is a small instrument by which a person can see for himself and watch the progress of the spots visible in the eye which a cataract is invading. It is described with twenty-two cuts in the *Ann. d'Ocul.*, September 1895, but has been rejected by oculists who do not approve of the patient studying the evolution of his trouble.

Suicidal Self-Medication. The London letter of the *American Practitioner and News* for Dec. 14, 1895, says:

"At Manchester, England, an inquest has been held on the body of a hawkier who, feeling unwell one day, took twenty pills. Next day he declared himself better and took eight more. The next day he died. His stomach was found red and congested as the result of his line of treatment. A verdict of death from natural causes was however returned."

Our Cuban Exchanges.—Science is supposed to raise its devotees above the cares and perplexities of life, and our esteemed Cuban exchanges are certainly a proof that this is the fact. They go calmly on their way, noting this and that "interesting case," with never an allusion to the wars and rumors of wars around them that the "special correspondents" are investing with such importance in the daily press. It is possible that if the censorship were removed, we might have a different tale.

Minnesota Provides Treatment for Inebriates. Minnesota is one of the States which, in 1895, provided for the treatment of inebriates by counties at a reputable institute within the State, the same to be selected by a committee of three citizens appointed by the probate judge of the county. The money used for such purpose is to be treated as a loan to the individual receiving the benefits thereof, for which he shall give a non-negotiable note, payable in five years without interest, which the probate judge may, in his discretion, extend at maturity. Besides this, in chapter 155, of laws of 1895, provision is made for the examination and commitment of inebriates to the special department for the treatment of inebriates in the Rochester State hospital.

Commitment of Insane in Minnesota. The Minnesota Legislature has, in chapter 119 of the general laws of that State for 1895, reenacted, in an amended form, a number of the sections of chapter 5 of laws of 1893, entitled, "An act to confirm the

location of the Minnesota hospitals for the insane, to provide for the commitment thereto, the management and supervision thereof, and the licensing and supervision of all other hospitals for the insane. This was necessitated, for the most part, by a decision of the supreme court of the State, early in 1894, that the sections of the original statute which prescribed the course of procedure and authorized commitment of persons to hospitals for the insane, were invalid because in conflict with those provisions of the State and federal constitutions which forbid that any person shall be deprived of his life, liberty or property without due process of law. The new enactment gives the procedure prescribed a little more the character of a judicial inquiry and determination.

A New English Ambulance; the Pneumatic Tire for Ambulances.—The letter-writer from London to the *American Practitioner* thus writes of an improvement recently adopted for ambulance purposes in the city named:

"A new pattern of ambulance, called the 'Salvator,' is being adopted by many corps of the St. John's Ambulance Brigade. The most notable defects in most ambulances are the liability to downward position of the head of the patient, the screws, pins and straps liable to be lost, the fitting together of various portions, and the many things to be done at the time of emergency. In the Salvator the stretcher is simply laid on a light iron carriage, and at once the two are securely locked together. The carriage is fitted along one side with a box containing splints of various sizes, and under the head end of the carriage there is a box containing bandages, scissors, tourniquet, and other appliances. Great attention has been given to the balancing of the litter, so that perfect horizontality shall be preserved."

The use of the pneumatic and rubber-rim tires are under trial upon certain wagons, just as in this country, where they are in use in a number of our cities. A guarantee of a year's wear can be had for wheels that sell for about \$100 per pair.

Medical Corps in Minnesota National Guard.—In 1895 there was a law passed providing that there shall be a medical corps in the national guard of the State of Minnesota under the direction of the surgeon-general to consist of one medical director with the rank of lieutenant colonel, three surgeons with the rank of major, and seven assistant surgeons with the rank of first lieutenant, except that an assistant surgeon who has served as such for five consecutive years, shall be eligible for promotion to the rank of captain. And in case of an increase in the number of State troops, the number of the medical corps is to be enlarged in a ratio of three medical officers to a regiment, and one medical officer for single troop of cavalry or battery of artillery. Candidates to fill vacancies in rank of first lieutenant must not be over 45 years of age, graduates of a recognized medical college, stand an examination by a board consisting of three members of the corps, and be reported by the surgeon general as fully qualified. The duties of the medical director are quite fully outlined in the statute, as are also those of medical storekeeper, which functions he may fill, or may detail some medical officer to fill. Hospital stewards shall serve as apothecaries, head nurses in hospital and assist the surgeon in keeping records of his department.

Surgery in Ruptures. The *St. Peters. Med. Wochens.*, of Dec. 28, 1896 is almost entirely devoted to a long article on this subject by Dr. Greiffenhagen, addressed more particularly to country physicians, urging prompt and radical surgical treatment of intestinal ruptures, as modern science has deprived it of all its dangers. In the young especially, there can be no question of an operation if a temporary truss does not cause the rupture to heal of itself. The working classes also need surgical treatment to relieve them of the expenses of trusses and bandages, and whenever a patient expresses a wish for such treatment, that in itself is sufficient indication, unless there is hernia to such an extent that the abdomen is really unable to contain the intestines. Another suggests the Condamin operation for umbilical rupture; the Kocher-Salzer operation for

femoral and the Macewen for internal inguinal rupture. In the treatment of external inguinal, another prefers Kocher's to begin with, but concludes with either Macewen's, Frank's or Bassini's. His historic account of the treatment of rupture from the days of antiquity to our own is very interesting, and he asserts that we will not be far wrong in assuming that one of every thirty or forty throughout the world, is ruptured more or less.

Professor Albert.—We are glad to learn from the *Klin. Rundschau*, of Vienna, that Professor Albert has recovered from the attack of gout which prostrated him during the Christmas holidays. He has decided to restrict himself to the charge of his clinic this winter, and not attempt to lecture. His amphitheater is undoubtedly one of the worst in existence and his health would certainly suffer if he were to lecture where the thermometer is often as low as 7 degrees C. Professor Hochegg is suggested as lecturer in his place.

The "Mother's Friend" and the Infant's Murderer.—The enormous consumption of opiates among the poorer class of English cities crops out from time to time, and we give below an item from the *Press and Circular* that shows that even grocers are heavily engaged in selling the infant-killing narcotics. "The extent of the trade in infant hypnotics may be judged from the evidence presented in a recent prosecution by the Pharmaceutical Society of England against a grocer for selling one of these nostrums. This concoction, which is called the 'Mother's True Friend,' was a mixture of Epsom salts and morphia, to the amount of one grain of the latter to the ounce of water. The defendant pleaded that he had sold two gallons a week of the liquid for the last twelve years, but he admitted that for the privilege of doing so, he had paid already £25 as fines to the Pharmaceutical Society upon five separate convictions. He was fined another £5."

The Modern Arabian Medical Practice.—If the following be a true description of the modern Arabian school of medicine in Northern Africa, what must have been the measure of the harshness of that school in the earlier times? In the course of his description of life in Morocco, in "The Church at Home and Abroad," Rev. James Johnston thus describes the course of treatment adopted by the Moorish physician:

"For a woman to be ill in Morocco is a misfortune indeed. If in a state of suffering, the Moorish woman is allowed, infrequently, to go to the native doctor, who is seated in the marketplace, surrounded by the implements of his calling. An array of flat irons, a small firepot of charcoal, and a huge black bottle constitute his stock in trade. Whatever the disease, external or internal, there is invariably one remedy. He places the iron in the fire until it is hot, and then applies it to the part affected, after which the patient must swallow a draught of a mysterious potion. What this barbarous ordeal entails may be more easily imagined than described. To the rescue of their suffering sisters from such misery, an increasing band of qualified lady physicians are devoting themselves, and they are welcomed where the male medical missionary is refused admission."

Hemicrania or Migraine not a Local Trouble.—Bary adopts Moebius' theory that migraine is a general morbid condition and not necessarily a local trouble, and consequently asserts that the pain can present itself in other parts of the body as well as the head. (*Neurol. Centralbl.*, No. 6.) He cited in confirmation of his assertion the case of a woman belonging to a family in which serious nervous troubles were hereditary. She was subject to excessively painful migraines. Occasionally the pain in the head would stop abruptly, but would be immediately superseded by a severe pain in the epigastric region. The gastro-intestinal functions showed no disturbance but were perfectly regular through these paroxysms. There was no hysteria, no neurasthenia.—*Bulletin Méd.*, Jan. 12, 1896.

Treatment of Hydrocele with Injection of Concentrated Carbolic Acid.—The *Centralbl. f. Chir.*, Jan. 4, 1896, gives an account of the results of this treatment in Professor Bruns' clinic. Of

forty-seven cases treated, twenty-eight were cured with sac injection; four with two, and two with a simple puncture a few weeks after the injection. In the six cases that were not healed, the trouble was so slight with four when it reappeared as not to necessitate treatment. There never were any symptoms of intoxication in any of the cases. Professor Bach writes to the *Klin. Chir.* in regard to the above and compares this treatment with the results obtained from iodine. The advantages are about even, he concludes with this in favor of carbolic acid, that it is painless and does not require any interruption of the usual occupations. A Russian clinic, Rasumowski's, of Kasan, has also had considerable success with carbolic acid as described in another article in same number. A saturated alcoholic solution of carbolic acid was used in this case.

A Curious Mistake; "Tyson's Glands."—Dr. James Tyson, of Philadelphia, writes to the *New York Medical Journal*, January 4, for the purpose of disclaiming a discovery erroneously accorded to him by a fellow-countryman of the real discoverer. It appears that in a paper by Dr. Finlayson on Eponymic Structures, in the *Glasgow Medical Journal*, December, occurs the following: "Tyson, James T., American professor of pathology, physiology and microscopic anatomy. Born at Philadelphia, 1841. Glands of (prepuce and labia)." The letter of our American Dr. Tyson says: "As I am evidently intended in this reference, I think I should state that I am not so fortunate as to have discovered these glands. They were described probably over two hundred years ago by Edward Tyson, M.D., Fellow of the College of Physicians and the Royal Society, Physician to the Hospital of Bethlehem, and reader of anatomy at Chirurgeon's Hall, who was born in 1649 and died in 1708." Another curious error in names recently perpetrated in one of our New York contemporaries is the reference to Sir Richard Quinn, of London, as "Sir Richard Quinn."

The Manhattan State Hospital for the Insane.—The Governor of New York State is required by law to make, early in February, appointments to the Board of Managers of the above named institution, which is the new name of that notorious public retreat, the New York City Asylum. The act under which the transfer of this abode of neglect and mismanagement was transferred to "State care" was approved on January 28. The *New York Herald* says: "The new board is to consist of seven persons, two of whom shall be women, and all shall be residents of the city of New York. They shall hold office for one, two, three, four, five, six and seven years. It has been expected that under the new regime of the State Lunacy Commission the old management of the asylums and the abuses which went on under the eye of the general superintendent, Dr. A. E. Macdonald, would be discontinued, but there is some likelihood that the old management will be quite as much in favor with the Lunacy Commissioners as it was with Tammany Hall."

Pathological Department of the New York State Commission in Lunacy.—An appointment by the above named commission has been made to the position of Director of the Pathological Institute of the State Hospitals for the Insane, after a competitive examination in accordance with the civil service laws of the State. This new position has been established under an act passed by the legislature of last year. Dr. Ira Van Gieson, of New York city, has passed the required examination in general pathologic anatomy, architecture of the nervous system, minute anatomy of the nervous system, pathologic anatomy of the nervous system, technique and methods of neural investigation and the lines of research to be applied to study of the pathology of insanity. Dr. Van Gieson has been connected with the laboratory of the College of Physicians and Surgeons, New York, for ten years past as instructor in normal histology and neurology, and is regarded as an authority on microscopic technique and the pathology of the brain and nervous system. His

selection was highly indorsed by many prominent members of the medical profession. The laboratory, which is to be maintained for the benefit of all the State hospitals, will be conducted on a scale which has not hitherto been undertaken by any State or country, the aim of the commission being to provide for an exhaustive study of all the morbid conditions that underlie mental diseases, from the standpoint of cellular biology, which is now elevated to the dignity of a special science; also to provide instruction in brain pathology and allied subjects for the medical offices of State hospitals. Official bulletins representing the progress of the laboratory work and the clinical work of the State hospitals will be issued quarterly.

Amendment of Tennessee Pharmacy Law. Chapter 39 of the Acts of Tennessee of 1893, establishing a board of pharmacy, and regulating the practice of pharmacy, the sale of poisons, and prohibiting the adulteration of drugs, was amended in 1895, making the provisions thereof apply only to incorporate cities and towns, and taxing districts of the State, and providing that all persons brought within the provisions of the law, by these amendments, shall be entitled to registration without examination, on the same conditions as provided by the original act. Section 3 is amended by adding thereto that it shall be the duty of every registered pharmacist, or assistant pharmacist, upon changing his place of business from one town to another, or upon leaving the State, forthwith to notify by letter the secretary of the board of pharmacy of such change in location. It shall also be the duty of every registered pharmacist, or assistant pharmacist, to notify by letter the said secretary on or before the 30th day of June in each year, whether he or she will continue the practice of pharmacy at registered place of business. The secretary of the board shall notify by letter, to the address as appearing on his books, every registered pharmacist, or assistant pharmacist, who shall not have notified him as thus provided, that renewal of registration is required, and in case an answer enclosing the necessary fees shall not have been received by the secretary within thirty days from the date of such notice, such name shall be stricken from the register.

Statistics of Serotherapy in Diphtheria in Germany.—Prof. Behring delivered a recent address on this subject in which for the first time, he replied to the swarms of critics who have been attacking him the past year or so. He maintained that statistics prove the efficacy of his serum, and that the 60,000 deaths from diphtheria which the empire has averaged each year will be found to be reduced to 40,000, and a more general use of the serum would reduce this to one-third. Throughout the city of Berlin the fatality in diphtheria amounted to 30 per cent., but in the Contagious Hospital, where serum was promptly used, the mortality was only 20 per cent. In the same time in 1895, it was only 10.3 per cent. The mortality in the hospitals had always been much greater than outside heretofore. Last year the percentage of mortality in diphtheria cases in Berlin fell to 15 per cent. During this period the disease was not a mild form, but averaged more morbid symptoms than at any time since 1886. During the first three months of 1894, when the serum was not to be had, there were 363 deaths per 1,000, while the last three months, when everybody could get the serum, there were 198 deaths per 1,000. Summing up the figures, there were 10,312 diphtheria cases reported: 5,823 treated with serum, with a mortality of 9.6 per cent. In 4,479 cases it was not used, and the mortality was 14.7 per cent.

Use of the Blood of the Viper and Common Adder as an Antivenomous Substance. According to the *Medical Week*, Drs. Phisalix and Bertrand have addressed the French Academy of Sciences on the above subject. In their preceding papers they have shown that the blood of the viper and common adder contains toxic principles analogous to those of venom. The immunity

of these animals to their own venom they regard as the result of habituation. They have since carried out further experiments, the results of which suggest the possibility of another explanation. Having found that the natural immunity to adder poison enjoyed by the hedge-hog is due to the simultaneous existence in the blood of this animal of toxic and antitoxic substances, they have endeavored to ascertain whether the same is not true of the blood of the viper also. With this object in view, they subjected viper serum to a temperature of 58 degrees C. during fifteen minutes, and then injected it into the peritoneum of several guinea-pigs. Half a cubic centimeter of normal viper serum is sufficient to kill a guinea-pig, but several cubic centimeters of the heated serum determined no ill effect of any kind, which proves that the toxic substances normally contained in the serum had been destroyed. Dr. Calmette has already called attention to the fact that the blood of the naja tripudians, naja haje, rattlesnake and horned viper loses its toxic properties when heated for ten minutes at a temperature of 68 degrees C. Moreover, injection of heated serum immunizes the animal against the poison, as they have ascertained beyond question by experiment. The antitoxic power of this heated serum is considerable, for on several occasions an injection of a quarter of a cubic centimeter proved sufficient to immunize a guinea-pig against the lethal dose of poison; but this immunity was of short duration, passing off within a few days. Similar experiments with the blood of the common adder gave the same results, except that the antitoxic power in this case was somewhat inferior to that of viper's blood. In the viper and common adder therefore, as in animals which have been artificially vaccinated or immunized, antitoxic substances are produced by a defensive act of the organism, and it is possible that the immunity of these reptiles to their own venom is the result of auto-vaccination, as it were, rather than habituation. In any event, the existence in the blood of the viper and common adder of antivenomous substances is a point of great importance in respect of general physiology, because it proves that, in proportion as the cells of an organism secrete toxin an antagonistic reaction takes place, which results in the formation of a specific antitoxin.

Association of American Medical Colleges. Important Decision.—

OHIO MEDICAL UNIVERSITY.
COLUMBUS, OHIO, Dec. 22, 1895.

DR. BAYARD HOLMES, Sec'y Ass'n American Medical Colleges, Chicago, Illinois.

Dear Doctor:—In my duties as Dean of Medical Department Ohio Medical University, several questions have arisen from time to time on which I have not been able to find rulings in proceedings or constitution of the Association. In some of these cases prospective students may have interests at stake which in deserving cases I might not desire to ignore without first giving their cases careful consideration. In others the University would not desire to grant any concessions, no matter what personal merit there was in the case, without a certainty that they were permissible under the rules of the Association.

In view of these knotty problems I have desired to get opinions on questions that may arise again. Our sessions run from the middle of September until the latter part of May, being divided into full, winter and supplementary terms. Attendance on the latter term is not a requirement of the regular annual session, and commencement exercises are held at the close of the winter term in March. The work of the supplementary term is carried on by our regular faculty, and if a student matriculates for it he is required to carry a full quota of work, and in clinical studies he has unusually good advantages.

Under our plan of teaching (grading from daily recitations) record of non-attendance is complete. It has been our rule that sickness or other satisfactory cause can not excuse from more than 20 per cent. of session. In deserving cases, students of undoubted scholarship and work, the question arises, can "conditions of time" i.e., lack of the required 80 per cent. attendance of regular session, be removed by attendance upon this supplementary term, provided that their scholarship comes up in every way to the usual standards? In other words, can a man whose deficiency is one or two weeks time alone,

overcome this by two months in the supplementary term, or must he be held over for the regular required session of the following year?

We have a senior student who has been sick for eight weeks this fall with typhoid fever, and during this time was under the care of our staff in the University Hospital, and he raises the question whether, if his scholarship is proven worthy, he can not remove the limitations of lost time by two months in the supplementary term and be given his diploma at the end of that time.

Another question. A. is a student in the literary department of an institution and in January transfers to the medical department of the same school and, in July receives credit for first year's work, he having been in this school some two or three years and received the degree of B.S. Is such a student eligible to second year of a regular winter session college the September following, on passing examinations in the first year branches? A literal construction of the rule that no two courses shall be in the same twelvemonth leaves room for discussion as to its application in such a case.

We have a student who for sufficient reasons desired to take his course at the Ohio Medical University and applied a year ago this fall for admission to our junior class. He had in July completed his first course, but had been a student as stated above, possessed the B.S. degree. We declined to matriculate him as a candidate for the degree at the end of two sessions, and of his own election he agreed to enter and take the work, and allow the question of his eligibility for degree to come up later. That question has now arisen. He attended the regular session last year, including the supplementary term. He has been in the office of one of our busiest practitioners. His scholarship is unexcelled in the University, and in every way he has shown himself to be a capable man. This year he was chosen from a large class as assistant to hospital staff. Can he in accordance with the laws of the Association, be given the degree of M.D. at the close of the required session in March?

I regret to trouble you, but you will be able to give answers more briefly than I have been able to put the queries. Thanking you for your kindness, Very truly yours,

[Signed] J. E. BROWN, Dean.

ANSWER.

1. No student, present or prospective, can have any legitimate interest sufficient to require any college to violate the provisions of Sec. 5, Art. III, of the Constitution. The meaning of the word "sessions" as used in the second line of the second paragraph of the letter to which this is an answer, is ambiguous. If they "run from the middle of September until the latter part of May" the object of dividing into "Fall, Winter and Supplementary terms" is not apparent to the Council. Such subdivisions of annual courses must be regarded as irregular.

2. No other instruction, excepting that given under the regular annual courses, can be accepted as any part of the graded instruction provided for in Sec. 5, Art. III, of the Constitution.

It is assumed that a student of medicine continuously pursues the study from the beginning to the conclusion of his collegiate career. The work of any supplementary term can be regarded as additional facilities offered by the college conducting it, and it might be construed in the light of increased advantage to its students.

There is no rule of the Association which recognizes "grading from daily recitations." Intermediate examinations are provided for at the end of any regular session. Entrance examinations for advanced standing must be conducted at the beginning of the regular sessions. Intermediate studies can not be recognized as fulfilling the requirements of any portion of the annual courses provided for in the Constitution, as at first adopted, nor as amended to take effect in 1899 and thereafter.

A certain degree of discretion must be exercised by the Deans of colleges, but it can not be allowed that any college may, with impunity, disregard any of the provisions of the Constitution of the Association.

3. The time requirements of the Association are fundamental, and no amount of sickness can be accepted as an excuse for absence from college duties. It is the student's misfortune if ill health interrupt his studies; and, if he may be excused from two months of the six required for one annual course, he may be excused from an equal period in each of the succeeding years. The purpose of the time requirement, in connection with the graded system, is to secure a certain standard of scholarship, which would be impossible for those physically unable to pursue the course of study.

4. The requirements of Sec. 5, Art. III, of the Constitution

would be violated by permitting the student to receive credit for a second annual course of instruction beginning at any time of the same year in which his first course had begun. A student, therefore, beginning his collegiate training in an institution whose annual sessions begin in January can not be permitted to enter, the following September, an institution whose annual session begins at that time, or prior to the month of January. Colleges whose annual sessions begin in September can not receive a student in January, and give him credit for a full course of instruction terminating at any time prior to the end of the next ensuing session after the January admission.

5. The student referred to as having attended "the regular session last year," and, as having "been in the office of one of the busiest practitioners" can not be admitted to final examination for the degree until he has completed three courses of six months each, in three separate years, prior to 1899.

J. H. ETHERIDGE, M.D.

International Medico-Military Statistics.—Dr. Myrdacz, Secretary of the International Committee on Uniformity of Medico-military Statistics of which Lieut.-Colonel John S. Billings, U. S. A., is chairman, has issued to the various governments a review of the state of the negotiations of the Committee to date. The statistical tables presented by the Committee for adoption are ten in number: I, report of examination of recruits; II and III, movements of sick by departments; IV, by corps of service and months; V, by larger garrisons and VI and VII, by important diseases; VIII, admissions of important diseases by corps and IX, by months; X, deaths according to years of service and age.

FRANCE declared Feb. 24, 1895, that her statistics would be changed to correspond with the plan proposed by the Committee, with the exception of her recruitment, which will not be included in her statement. No further communications were received since that date.

RUSSIA forwarded May 18, 1895, complete tables, agreeing very nearly with the Austria-Hungarian plan. The headings are in the Russian and French languages. Deviations from the plan consist in the following points:

1. The Sanitary Corps does not exist in Russia as a separate body, but is comprised in the "Troupes auxiliares."

2. In table VII the position for "Days lost by Sickness" has been omitted.

3. In table VI the same omission is made.

4. Table I is arranged by "Gouvernements," and as the recruitment is a part of the duties belonging to the Department of Interior, it follows that this table has first to be constructed by the medical branch of the War Department.

THE UNITED STATES OF AMERICA will annually forward hektographed tables to the Chief of the foreign Medical Departments, and expect an equal courtesy on the part of Austria-Hungary. As in America, the losses by "Disability," are considerably in excess of those by "Disease," the desire is expressed that in tables II, III, IV, VI and VII the losses by "Disability" should be stated separately. Table VIII brings the absolute figures. [The International statistical Tables for the calendar year 1894, were published in the last annual report of the Surgeon General of the army.—J. B. H.]

AUSTRIA-HUNGARY has adopted the blank forms submitted by the Secretary of the Committee. It is proposed to conform to them in the publication of the sanitary statistics for the year 1894.

ENGLAND forwarded Feb. 22, 1895, complete blank forms, which differ from those of the Austria-Hungary plan in the following points:

1. Positions 5-15 are not expressed in centimeters, but in feet and inches.

2. Position 18 is headed "Defective Vision," and position 19 "Heart Diseases," while the original table proposed respectively, "Myopia" and "Defective Heart" (vitium cordis organicum).

3. On tables II and III position "Treated in Quarters" is omitted, and the position for "Loss other than by Death" is subdivided into the positions "Sent Home" and "Discharged." The position "Days lost by Sickness," is substituted by "Constantly non-efficient from Sickness."

4. In table IV the number of patients treated in quarters is

omitted, and position for "Constantly Sick" is newly supplied.

5. Table V is omitted.

6. On table VI and VII the patients returned to duty are not given, and the "Days lost by Sickness" are substituted by the column "Average constantly Sick."

6. Tables VIII and IX are omitted.

BAVARIA, by a communication dated Jan. 26, 1895, has fully adopted the Austria-Hungarian plan, but desired that the position headed "Otherwise Disposed of" be subdivided into "Invalids" and "Unfit for Service."

DENMARK referring to the Austria-Hungarian plan, forwards May 26, 1895 the following remarks:

1. In table I conscripts of not less than 21 years of age are mentioned, while in Denmark conscripts from 18 to 20 years old are brought before the examining board. It is asked whether rejection for being "Under Height" are in all cases definite or only temporary. Positions 5 to 10 should contain not only those fit for service, but all who have been under treatment. The diagnosis "Physical Debility" should, by remarks, be clearly defined.

2. In reference table VI the question is asked how to count a patient who is first admitted to quarters, and afterwards for the same disease to hospital. In regard to tables II to IX, information is desired how to tabulate patients treated on account of attempted suicide or accidents, and who subsequently die.

As in Denmark only patients are treated in quarters whose complaints are of the most trivial character, which hardly warrant diagnosis, the reports will include none but hospital patients.

PRUSSIA has not yet forwarded her decision in regard to her adoption of the plan.

BELGIUM has not yet communicated her decision.

ITALY accepts the Austria-Hungarian plan with the following remarks:

1. It will be impossible to entirely conform to the plan prior to 1897. In the reports for 1895-1896 the tables will be partially used, as has already been done in the report for 1894, recently published.

2. An abundant and regular exchange of the completed tables is desired.

3. In table I the classification will be given by military divisions.

4. In tables II and III a column should be interpolated next to that headed "Deaths," giving the deaths occurring outside of sanitary establishments.

5. In addition to the Division Headquarters, only garrisons with a minimum strength of 1,000 will be given.

6. In tables VI and VII "Pleuritis" and "Ulcus molle" (Chancroid?) should be inserted.

7. In table X ratios instead of absolute numbers should be stated, and an additional column is required for deaths of soldiers under 20 years of age.

8. It would be desirable to have an understanding in regard to the manner of computing the mean strengths. In Italy the sum of the daily rations due to men actually with their colors, to those treated in sanitary establishments, and to those furloughed (less than three months) are, at the end of the year, divided by 365. Is the same practice observed in other armies?

9. The questions are asked whether the cases of men dying in sanitary establishments, after having been discharged from the army, are to be considered as deaths, or simply discharges? If a man, when under treatment, contracts a disease of an entirely different kind from that for which he was originally admitted, would his case constitute one or two admissions? If a man dies after a shorter or longer absence from his colors, should his case be included in the statistical report?

The following communications were received from governments not represented at the Committee meeting at Buda-Pesth:

Norway has appointed Capt. Dr. Trap-Jensen, of Christiania, as her representative on the Committee, but will furnish no other data than that in regard to recruitment, a regular army as such having no existence.

SPAIN appointed as her representative on the Committee, Dr. Joseph Reig Casco, of Madrid, who is attached to the military household of the Queen Regent.

HOLLAND will adopt the appendix to the Austria-Hungarian plan for her report of 1895. The following exceptions are taken:

1. Column "Otherwise Disposed of" should be subdivided into two columns headed respectively, (a) "Unfit for Service," and (b) "Otherwise Disposed of."

2. In tables VI and VII under "Gonorrhea" and "Syphilis" the original admissions only should be tabulated, omitting relapses and chronic cases.

3. Headings of tables and other writings should be in the Latin or French language, or one of these languages should be

employed to translate the terms used by the different nations.

4. A short description of the prevailing system of recruiting should be added, and the requirements for acceptance stated.

Health Officer of the 1st Class, W. H. L. Borgershoff, in charge of the military hospital at Middleburg, was appointed as representative on the Committee.

Practical Notes.

Sulphur as a Cure for Acne and Facial Eruptions.—Dr. Barrière, of Paris, has cured many cases of this nature that refused to yield to other measures. He used it alone or combined with general treatment. Its advantages are obvious and its efficacy is thoroughly established.—*Rev. Int. de Méd. et de Chir.*, Jan. 10, 1896.

The Kastorsky "Cure" for Diphtheria.—This cure is a 10 per cent. alcoholic solution of menthol, with which the fauces are sponged off. It is applied on a piece of cotton. Thirty-seven cases treated were cured, some with one application. Several cases also were treated where the diphtheritic angina was complicated with scarlatina.—*New York Correspondence Revista de Ciencias Med.*, Jan. 5, 1896.

Leucoma.—Dr. Germann noticed the peculiar triangle produced by a steel pen dipped in ink, with which one schoolboy had struck another in the cornea, and he has applied this observation in tattooing for leucoma with highly satisfactory results. Instead of the usual pointed lancing pencil he used one that produced a triangular mark, and accomplished the operation in less than a quarter of the usual time.—*St. Petersburg Med. Woch.*, Dec. 28, 1895.

Actinomycosis in the Lungs.—Heusser describes a case of this kind in the *Bert. klin. Wochensch.* which baffled diagnosis for a long while, the symptoms being typically characteristic of pleurisy, and later of tuberculosis, until the fungus actinomyces was found in the sputa. It shows the necessity of being a bacteriologist in order to diagnose successfully nowadays.—*Gaz. Méd. de Paris*, Jan. 11, 1896.

Preliminary Exploratory Operation.—Prof. Tansini, of Palermo, recently performed an exploratory operation for the purpose of diagnosing a renal trouble, which the *Gazzetta degli Ospedali e Cliniche*, of Jan. 11, 1896, commends as an innovation worthy of note. Instead of operating upon the diseased kidney he opened up the other one, thus learning the condition of the capsule, etc. Finding everything sound he sewed up the opening entirely, taking stitches in the capsule, the muscular tissue and the skin. Then he proceeded to perform nephrectomy with confidence, and the patient was soon restored to perfect health.

Intravenous Injection in Post-operative Sepsis.—Dr. Berlin, of Nice, recently had a case of violent septicemia following a vaginal hysterectomy, that showed the fatal symptoms of dyspnea, subnormal temperature, inflated and painful abdomen, etc. When death seemed imminent Dr. Berlin injected 600 g. of Hayem's artificial serum into the patient's veins, and followed it with 800 g. At first all symptoms grew worse and cyanosis soon followed, and twelve days after operation patient was discharged cured. (Case reported to the Soc. de Chir., and described in the Paris letter to the *Therapeutische Wochenschrift*, of Jan. 12, 1896.)

Cystic Formations at the End of the Optic Nerve.—Sachsaler describes, in the *Beiträge zur Augenheilkunde*, a case where small cysts formed at the level of the papilla of the optic nerve, situated below the vessels of the retina, resembling small knobs in appearance. The patient died of an intercurrent disease and the autopsy showed that these cysts were produced by a hyaline transformation occurring in the nerve cells, forming actual hyaline concretions. The absorption of these concretions produced the cysts. The walls of the vessels of the papilla showed also the results of a thickening process.—*Gazette Médicale de Paris*, Jan. 11, 1896.

Treatment of Night Sweats in Phthisis.—

R. Salicylic Acid	2 grams.
Distilled water	10 "
Alcohol	6 "
Neutral glycerin	4 "

This mixture is for subcutaneous injections. Inject before retiring 2 cubic centimeters for four or five days.—*Jour. de Méd. de Paris*, Jan. 12, 1896.

Cancer of the Supra-renal Capsule.—Stonkoventoff recently described a case of this kind that is worthy of note in some respects. The patient was a woman of 50 who began to have a cough, fever and intense pains in November, 1894. Lungs seemed affected, liver hypertrophied to some extent, and finally she died with every symptom of pulmonary trouble. The autopsy showed the origin of all this functional disturbance to have been a cancerous growth on the supra-renal capsule, which displaced the liver somewhat, but had not affected the kidney.—*Gaz. degli Osp. e Chir.*, Dec. 28, 1895.

Insufflating the Bowels with Boracic Acid.—Merkel, of Munich, has been treating some cases lately where gases have accumulated in the bowels, producing great discomfort, accompanied with constipation, according to Flatau's suggestion of insufflating the intestines with boracic acid. He has been successful, and although relapses occurred in several cases, they soon yielded to a permanent cure. He used each time 2 to 4 gms. boracic acid with which the intestines were insufflated as high as possible by means of a rubber tube and ball. The process was repeated two to six times a week for some time.—*Münchener Med. Wochenschrift*, 1895, No. 52.

The Disinfection of Tuberculous Sputa with Wood Vinegar.—As it is impossible in private life to use the methods of disinfection practiced on such a large scale in hospitals, and as it is important to have these germs killed, Dr. Goriansky has been conducting a series of experiments at St. Petersburg, the result which he announces is the discovery that wood vinegar, or pyroligneous acid, will kill that almost indestructible Koch bacillus, as it is found in sputa. Wood vinegar, we know, contains guaiacum, cresols and acetic acid. It probably owes much of its intense antiseptic action to the fact that the guaiacum is found in it in an acid solution, and also to the acetic acid it contains in considerable quantities.

Kobert's Cornutin.—This remedy has not proved reliable in a number of cases in Vienna (*Wien. klin. Wochens.*, Nos. 22 and 23, 1895), where it was used to control uterine hemorrhages due to atony of the muscles after confinement, and in other gynecologic troubles. In two cases where the desired result was finally obtained it was only temporary and the uterus soon relaxed again. The effect of ergotin is persistent, and in every way it is superior to cornutin. Some fowls experimented on with cornutin to ascertain its hemostatic value proved the superiority of freshly prepared ergot. No experiments were made with it in regard to producing labor.—*Les Nouv. Remèdes*, Jan. 8, 1896.

Puerperal Multiple Neuritis.—The *Lyon Méd.*, No. 51, reports a case of multiple neuritis accompanying childbirth. The first symptoms showed themselves during the last month of pregnancy, accompanied with frequent vomiting. There were pains, burning and tingling sensations in the limbs, which became very weak and emaciated, and after birth of child these symptoms increased, until the lower limbs became absolutely impotent, the arms relatively so. It required three months' treatment with hypodermic injections of ergotin, and electric baths for the lower limbs only, to restore them to health. The action of the bladder and rectum remained normal through it all. The cause did not seem to be any auto-infection, but rather the debility of patient, which affected her like marasmus or chlorosis, which are often complicated with multiple neuritis.—*Bull. Méd.*, Jan. 12, 1896.

Intestinal Antisepsis.—M. Huchard's paper delivered before the Société de Thérapie last month is an eloquent plea for the rational use of intestinal disinfecting washings. He has secured some magnificent results from them in cases of chlorosis and uremia, which he has completely cured in this way. He defines uremia, with Bouchard, as an intoxication of the system produced by the various poisons introduced into the system which the kidneys fail to eliminate. He introduced two liters of salted water at 40 degrees C. into the rectum, plugging the anus with cotton around the tube. With three liters the liquid floods the intestines almost the entire length, and six liters will penetrate even into the stomach, from which it has been withdrawn through the mouth, thus entirely reversing the order of nature, which is not to be commended. He predicts a great future for this safe, easy and reliable medication as its true value becomes better recognized.—*Rev. Int. de Méd. et de Chir.*, Jan. 10, 1896.

Lannelongue's method Applied to Vascular Tumor Invading Neck Face, Mouth and Tongue.—The *Bull. Méd.*, Jan. 12, 1896, describes the cure of a tumor of this kind on a woman of 28, following the course of the lower maxillary, and probably congenital, as patient could not remember when she did not have a bunch there. It was a soft, pulsating, vascular tumor, such as Dupuytren calls an arterial varix, and no operation was to be thought of, except as a last resort, ligature of the carotid. The pain and inconvenience of this immense excrescence were most distressing. Prof. Lannelongue used his sclerogenous treatment, viz., injections of 10 per cent. solution of chlorid of zinc, three or four drops at each puncture, injected in the surrounding tissues and in the tumor itself. Immediate relief ensued, and four sittings reduced the tumor to such an extent that no more were attempted. At present, three years have elapsed and the angioma has dwindled to size of a small nut, while a slow atrophic sclerosis has taken place throughout it, the surest sign of a permanent cure. (See this JOURNAL, Jan. 18, page 136.)

Castration to Relieve Hypertrophy of the Prostate Gland.—The last two numbers of the *Centralbl. für Chir.*, Jan. 4 and 11, 1896, contain each an account of a successful operation of this kind. One by Professor Bruns freed the patient from the catheter he had been compelled to use for six months. Professor Taisst writes to the *Klin. Chir.* in regard to this case, reviewing all the literature on the subject, and heartily endorsing double castration as the last and safest means of relief. He asserts that the disturbances of the psychic functions observed in some cases after castration, were due to previous causes, and not to the operation itself. The second case was treated by Dr. Roosing, of Copenhagen. A man of 85 had, for eleven years, never had one spontaneous discharge of urine, but had been compelled to use a catheter constantly. Operation became necessary as even smallest sized catheter caused pains and bleeding, and patient was wasting away from this and other complications. Two months after double castration patient was well and strong, with normal and natural urinations: the elasticity of the bladder almost completely recovered, and general health and spirits were restored in a remarkable degree.

Fatal Effects of Iodid of Potassium in a Case of Goitre.—A communication was read at the session of the Société de Thérapie, November 13, relating the death of a man who was being treated for a very large goitre, with four grams of iodid of potassium internally during the twenty-four hours, and an iodized ointment applied to the thyroideal region externally. The treatment relieved the patient materially, as in three weeks the goitre had sensibly decreased in size. But very soon after treatment commenced, besides the usual symptoms of rebellion against the medicine, there was repeated vomiting, tachycardia and trembling. The iodid was discontinued, but

the toxic symptoms persisted and grew worse until the patient died, a month from the time treatment began, with symptoms of strumipriva cachexia and exophthalmic goitre. The physician in charge attributes death of patient to the rapid atrophy of thyroideal substance, produced by the iodid. This and the experience of others testify that although iodid is of great efficacy in the treatment of goitre, yet those suffering from it are least able to stand it, on account of its effect in provoking changes in the glandular organs, as Reser and Lebert have shown.—*Rev. Int. de Méd. et de Chir.*, Jan. 10, 1896.

Asepsis in the Use of Catheters.—The *Przegląd Chir.* contains an article on the sterilization of bougies and catheters which the ordinary methods, dipping in antiseptic solutions, washing with hot suds, and even the use of sublimate, sulphuric acid and vapor from quicksilver, are far from accomplishing thoroughly. Some microorganisms are sure to be left in the instrument. Perfect sterilization can only be secured by exposing for an hour to air heated to 130 degrees C., or to a flow of steam for fifteen minutes. The author then describes an apparatus he has invented for this steaming process, and also commends highly Kutner's. Boiling water can be used for metal and Nélaton catheters. But soda or any irritating substance must not be added to the water, for fear some particle may lodge and inflame the membrane. The organs should be carefully bathed externally with sublimate, and the surrounding region. Nothing should be left undone to secure asepsis of the urinary passages, which is the most difficult part of the task, especially when there is inflammation, retention of the urine or hyperemia and lesion of the mucous membrane of the bladder. In injecting the sterilizing water care should be taken to keep the orifice open so that the liquid can run out again and not force its way into the bladder. Sterilized vaselin the author recommends to use on instruments. The catheter should be used every six hours in cases of retention, until it has completely passed away. This he considers a very important point.—*Centralbl. für Chir.*, Jan. 4, 1896.

Society Notes.

THE RUSSELL COUNTY MEDICAL SOCIETY held a regular meeting in Montgomery, Ala., January 22. The following officers were elected for the ensuing year: President, T. A. Johnson, Jernigan; Vice-President, W. B. Hendrick, Hurtsboro; Secretary and Treasurer, G. F. Hendrick, Crawford.—The Ramsey County, Minn., Medical Society held its annual meeting in St. Paul, January 27. The following officers were elected for the ensuing year: President, A. J. Gillette; Vice-President, G. E. Senkler; Secretary, C. R. Ball; Treasurer, O. S. Pine. The monthly meeting of the Binghamton, N. Y., Academy of Medicine was held January 21. At the annual meeting of the Denver and Arapahoe Medical Society the following officers were elected: President, Robert Levy; Vice-President, Edward Jackson; Secretary, S. D. Hopkins; Financial Secretary, F. P. Hershey; Treasurer, E. J. Rothwell.

Hospital Notes.

THE ANNUAL meeting of the Salem, Mass., Hospital Corporation was held January 22. The report shows 1,677 patients treated in all departments. The Brooklyn, N. Y., Israelite Hospital Association has plans under consideration for a new hospital for the Jews in the Eastern District. It has been resolved to locate the hospital in Queens County, near the city line of Brooklyn, and that the total running expenses shall not exceed \$400 a month. There are to be twenty-five beds in the building, and the privileges of the hospital will be extended to all, regardless of nationality or religion. A meeting was held in Indianapolis, January 22, to discuss the establishment of a State hospital with free and pay wards. A committee on organization was appointed. The sixth annual report of the Long Island Throat Hospital and Eye Infirmary shows that 4,909 patients were treated during the past year. At the annual meeting of the Board of Directors of the New York Post-Grad-

uate Medical School and Hospital, the following officers were elected for the ensuing year: President, D. B. St. John Roosa; Vice-President, Andrew H. Smith; Treasurer, Bache Emmet; Secretary, J. L. Skillin.—The new hospital presented to the city of Carlisle, Pa., by the widow of the late ex-Congressman, Lemuel Todd, was formally dedicated January 29.—The annual meeting of the contributors to the Allegheny General Hospital was held January 28. The report shows the number of patients treated since the establishment of the institution, in 1886, 11,430. Attention is called to the overcrowded condition of the hospital.—The annual meeting of the Brooklyn, N. Y., Hospital was held January 30. The officers were reelected.

DR. A. F. A. KING.—It was stated in this column, February 1, that Dr. A. F. A. King had resigned from Columbian College. It was Columbia Hospital, and not Columbian College, from which Professor King resigned.

Philadelphia Notes.

A FIRE occurred in the hospital of the Jefferson Medical College on the 28th ult., caused by the explosion of a partly empty barrel of alcohol in the drug department. The damage was slight, but the patients were badly scared.

THE MEDICAL CLUB held its annual meeting at the Hotel Bellevue on the 29th ult. Dr. Hobart A. Hare was reelected President, Dr. L. J. Deal, Secretary.

A NEW monthly medical journal has commenced its career in Philadelphia, the *Medical Council*, Dr. J. F. Taylor, editor. It is to be devoted to diseases of women and children, obstetrics and stirpiculture.

DR. WM. OSLER, of Johns Hopkins University, delivered a lecture by invitation before the James M. Anders Society of the students at the Medico-Chirurgical College, on January 21 "Pathology of Addison's Disease."

DR. T. G. MORTON was reelected President of the Academy of Surgery of Philadelphia.

St. Louis Notes.

REPORTS OF HEALTH OFFICE.—For the week ending January 25: Total number of deaths reported 177, compared with 187 for the preceding week and 173 for the corresponding period of last year. Births reported, 221. For the week ending February 1: Total number of deaths reported 174, compared with 165 for the corresponding period of 1895. Births reported 212. Contagious diseases reported during the week ending January 25: Diphtheria 68 cases, 9 deaths; croup 6 cases, 5 deaths; scarlatina 11 cases, 1 death; typhoid fever 5 cases, 1 death; cerebro-spinal fever 3 cases, 2 deaths; measles 30 cases, whooping cough 10 cases, smallpox 1 case. Reported during the week ending February 1: Diphtheria 56 cases, 8 deaths; croup 3 cases, 2 deaths; scarlatina 6 cases, 1 death; typhoid fever 2 cases, measles 17 cases, cerebro-spinal fever 1 case, 2 deaths; whooping cough 1 case, 1 death.

THE DUESTROW CASE.—On February 3 the jury rendered a verdict of murder in the first degree, after listening to testimony for three weeks. The defense was insanity, and the only chance for justice lay in the weight given to expert testimony. As is usual in cases of this kind, experts appeared for each side, with the result that the case was decided with but slight reference to the facts brought out by the medical testimony, and that expert medical testimony was again covered with popular discredit. The physicians, known as expert alienists, who testified to the prisoner's insanity were Drs. Bauduy, Bremer, Chaddock and Crandall; the experts testifying for the prosecution were Drs. Hughes, Mink and Norbury. With division of opinion among men of such repute it is no wonder that a jury of farmers should take the view that the prisoner's crime was an act of drunkenness as the simplest solution of the case, especially in view of the prejudice against the plea of insanity as an excuse for crime, and the particular prejudice in this case arising from the fact that the culprit's wealth has been regarded as a means, that would be used to obtain an acquittal.

Washington Notes.

WEEKLY REPORT OF THE HEALTH DEPARTMENT.—The report of the Health Officer for the week ended January 25 is as follows: Number of deaths (stillbirths not included) 112, death rate per 1,000 per annum 21.1, death rate per 1,000 per annum, corresponding week last year 17.8.

FOR THE EASTERN DISPENSARY.—The Commissioners have again recommended favorable action on the House bill "to authorize the purchase of the lot and building now rented by the Eastern Dispensary and Hospital."

MEDICAL SOCIETY.—At the Medical Society meeting held on the 29th ultimo, Dr. W. W. Johnston completed the report of the Committee on Public Health. Dr. Eliot read a paper on personal observations of smallpox patients at the City Hospital last year. Dr. McArdle read a paper entitled "Cod-liver Oil Both a Food and a Medicine."

TO INCREASE THE WATER SUPPLY.—By request of the District Commissioners, Mr. McMillan to-day introduced in the Senate a bill to amend an act, approved July 15, 1882, entitled "An act to increase the water supply of the city of Washington, and for other purposes." The bill empowers the Attorney General and Secretary of War to obtain all water rights at and in the vicinity of Great Falls, on the Potomac River. Within nine months from the approval of this bill the Attorney General and Secretary of War are required to make a written statement, specifying the lands they may deem necessary to take for the purposes of this act. The Court of Claims is authorized to appoint three persons to determine all controverted questions of fact arising in any suit that may be brought under the authority of this act.

FOR BETTER SEWERAGE.—A delegation of physicians composing the Legislative Committee of the Medical Society of the District appeared before a subcommittee of the District Committee for the purpose of recommending legislation by the House looking to increased sewerage facilities and improvement in the water supply.

TO REGULATE MEDICAL SCHOOLS.—The House committee has reported the bill to provide for the incorporation and regulation of medical schools and colleges. This is the bill prepared by the Commissioners, and provides that it shall be unlawful for any medical college claiming the authority, or actually conferring the degree of doctor of medicine, not incorporated by a special act of Congress, to conduct its business in the District of Columbia, unless such college shall be registered by the Commissioners of the District of Columbia and granted by them a written permit to commence or continue business in the District in compliance with the requirements of this act. Regulations are stipulated for issuing such licenses, and fines and punishments provided for violations of the law. The bill was amended to include dental colleges.

The deplorable ignorance of the lay public on the subject of vivisection, was very forcibly shown at the hearing granted last week by the Commissioners of the District, to those interested in Senate Bill 1552, entitled "A Bill for the further prevention of cruelty to animals in the District of Columbia." It was obvious that none of those who spoke in favor of its passage had the slightest conception of the subject under consideration, but it was apparent that sentiment and sympathy, born of impressions made by exaggerated anti-vivisection publications, actuated their misguided and deluded championship of the bill.

In the absence of knowledge of the subject, no one should chide these good-hearted men and women for the position they assume with respect to vivisection, and until those who are engaged in this branch of necessary scientific research explain to them how carefully, kindly and accurately their work is performed, together with the incalculable benefit obtained in saving human life and preventing the ravage of diseases, will the oft revived "fad," opposition to vivisection crop up.

The general government yearly makes large appropriations for the conduct of scientific prevention of diseases and death in man, beast and vegetation, and the valuable work done, with the more valuable and far reaching results consequently obtained by the departments of "Animal Industry," United States Marine-Hospital Service, Bureau of Medicine and Surgery, United States Army and United States Navy, and the laboratories of the different colleges and hospitals are sufficient to prove that vivisection is necessary, and that any restriction of its practice will seriously impede scientific research and higher education. Education of the masses, and particularly the misinformed opponents to this branch of research, and not acts of Congress, is what is necessary to silence objectors. The provisions and restrictions in the pending bill are sufficiently absurd and ridiculous to warrant its publication in full for criticism by the scientific world.

Prominent among those who presented unanswerable arguments against the passage of the Bill were: Drs. Samuel C. Busey, President of the Medical Society; Kleinschmidt, Magruder, Cook, Somers, and Woodward; Surgeon-General G. M. Sternberg, U. S. A.; J. J. Kinyoun, U. S. Marine-Hospital Service; Walter Reed, U. S. A. Medical Museum; D. E. Salmon, Chief Bureau Animal Industry; Dr. de Schweinitz, of the Bio-Chemie Laboratory; V. A. Moore, Pathologist; Wardell Stiles, Medico-Zoologist, and Dr. Schroeder, Director Experiment Station U. S. Department of Agriculture.

The Bill will never become a law, for Congress will appreciate the impropriety of retarding medical research and scientific investigations by the supervision of uninformed laymen.

IN THE SENATE OF THE UNITED STATES.

JANUARY 14, 1896.

Mr. McMillan introduced the following bill; which was read twice and referred to the Committee on the District of Columbia.

A BILL.

For the further prevention of cruelty to animals in the District of Columbia.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That hereafter no person shall perform on a living animal any experiment calculated to give pain to such animal, except subject to the provisions hereinafter prescribed. Any person performing, or taking part in performing, any experiment calculated to give pain, in contravention of this Act, shall be guilty of an offense against this Act, and shall, if it be the first offense, be liable to a penalty not exceeding one hundred and fifty dollars, and if it be the second or any subsequent offense, shall be liable, at the discretion of the court by which he is tried, to a penalty not exceeding three hundred dollars, or to imprisonment for a period not exceeding six months.

SEC. 2. That the following restrictions are imposed by this Act with respect to the performance on any living animal of an experiment calculated to give pain to such animal; that is to say:

a. The experiment must be performed with a view to the advancement by *new discovery of physiologic knowledge*, or of knowledge which will be useful for saving or prolonging life or alleviating suffering; and

b. The experiment must be performed by a person holding such license from the Commissioners of the District of Columbia as is in this Act mentioned; and

c. The animal must, during the whole of the experiment, be completely under the influence of ether or chloroform to prevent the animal feeling pain; and

d. The animal must, if the pain is likely to continue after the effect of the anesthetic has ceased, or if any serious injury has been inflicted on the animal, be killed before it recovers from the influence of the anesthetic which has been administered; and

e. No experiment shall be made upon any living creature calculated to give pain to such creature, in any of the public schools of the District of Columbia; provided as follows, that is to say:

1. Experiments may be performed under the foregoing provisions as to the use of anesthetics by a person giving illustrations of lectures in medical schools, hospitals, or colleges or elsewhere, on such certificate being given as in this Act hereinafter mentioned, that the proposed experiments are absolutely necessary for the due instruction of the persons to whom such

lectures are given, with a view to their acquiring physiologic knowledge or knowledge which will be useful to them for saving or prolonging life or alleviating suffering:

2. The substance known as urari or curare shall not for the purposes of this Act, be deemed to be an anesthetic: and

3. Notwithstanding anything this act contained, no experiment calculated to give pain shall be performed on a dog or cat, except upon such certificate being given as in this Act mentioned, stating, in addition to the statements hereinbefore required to be made in such certificate, that for reasons specified in the certificate the object of the experiment will be necessarily frustrated unless it is performed on an animal similar in constitution to a cat or dog, and no other animal is available for such experiment: and an experiment calculated to give pain shall not be performed on any horse, ass, or mule, except on such certificate being given as in this Act mentioned, that the object of the experiment will be necessarily frustrated unless it is performed on a horse, ass, or mule, and that no other animal is available for such purpose; and

4. Any exhibition to the general public, whether admission be on payment of money or gratuitous, of experiments on living animals, calculated to give pain, shall be illegal.

Any person performing or aiding in performing such experiment shall be deemed to be guilty of an offense against this Act, and shall, if it be the first offense, be liable to a penalty not exceeding one hundred and fifty dollars, and if it be the second or any subsequent offense, shall be liable, at the discretion of the court by which he is tried, to a penalty not exceeding three hundred dollars or to imprisonment not exceeding six months; and any person publishing any notice of any such intended exhibition by advertisement in a newspaper, placard, or otherwise, shall be liable to a penalty not exceeding ten dollars.

A person punished for an offense under this section shall not for the same offense be punishable under any other section of this Act.

SEC. 3. That the Commissioners of the District may insert, as a condition of granting any license, a provision in such license that the place in which any such experiment is to be performed by the licensee is to be registered in such manner as the said Commissioners may from time to time by any general or special order direct: *Provided*, That every place for the performance of experiments for the purpose of instruction shall be approved by the said Commissioners, and shall be registered in such manner as the said Commissioners may from time to time by any general or special order direct.

SEC. 4. That the Commissioners of the District, upon application as hereinafter prescribed, may license any person whom they may think qualified to hold a license to perform experiments under this Act. A license granted by them may be for such time as they may think fit, and may be revoked by them on their being satisfied that such license ought to be revoked. There may be annexed to such license any condition which the said Commissioners may think expedient for the purpose of better carrying into effect the objects of this Act, but not inconsistent with the provisions thereof.

SEC. 5. That the Commissioners of the District may direct any person performing experiments under this Act from time to time to make reports to them of the result of such experiments, in such form and with such details as the said Commissioners may require.

SEC. 6. That the Commissioners of the District shall cause all registered places to be from time to time visited by inspectors without previous notice, for the purpose of securing compliance with the provisions of this Act, and shall appoint and authorize an agent of the Washington Humane Society to make such inspection, and may also appoint such special inspectors as they may think fit, either permanently or temporarily, who may be willing to act as such inspectors gratuitously.

SEC. 7. That any application for a license under this Act, and for a certificate to be given as in this Act mentioned, must be signed by three physicians duly licensed to practice and actually engaged in practicing medicine in the District of Columbia, and also by a professor of physiology, medicine, anatomy, medical jurisprudence, materia medica, or surgery in the medical department of any duly established and reliable school or college in the District of Columbia: *Provided*, That when any person applying for a certificate under this Act is himself one of the persons authorized to sign such certificate, the signature of some other of such persons shall be substituted for the signature of the applicant.

A certificate under this section may be given for such time or for such series of experiments as the persons signing the certificate may think expedient.

A copy of any certificate under this section shall be forwarded by the applicant to the Commissioners of the District

but shall not be available until one week after a copy has been so forwarded.

The Commissioners of the District may at any time disallow or suspend any certificate given under this section.

SEC. 8. That the powers conferred by this Act of granting a license or giving a certificate for the performance of an experiment on living animals may be exercised by an order in writing, under the hand of any judge of a court of record having criminal jurisdiction in the District, in a case where such judge is satisfied that it is essential for the purposes of justice in a criminal case to make such experiment.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from January 25, 1896, to January 31, 1896.

Capt. Benjamin Munday, Asst. Surgeon, is granted leave of absence for one month, on surgeon's certificate of disability, with permission to apply for an extension.

First Lieut. William H. Wilson, Asst. Surgeon, is relieved from duty at Ft. Leavenworth, Kan., and ordered to Ft. Bayard, N. M., for duty at that post.

First Lieut. Harry M. Hallock, Asst. Surgeon, is relieved from duty at Ft. Bayard, N. M., and ordered to Ft. Logan, Colo., for duty at that post.

Capt. Benjamin L. Ten Eyck, now at Columbus Bks., Ohio, is ordered to Ft. Niobrara, Neb., for temporary duty.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending February 1, 1896.

Asst. Surgeon A. B. Pusey, detached from the "Cincinnati" and ordered to the "Vermont."

Asst. Surgeon G. C. Hubbard, detached from the "Vermont" and ordered to the "Cincinnati."

Asst. Surgeon C. M. De Valin, ordered to the naval hospital, Philadelphia. Surgeon J. M. Steele, detached from the torpedo station and ordered to special duty on the "Independence."

Surgeon M. H. Simons, detached from special duty at Portsmouth, N. H., and ordered to the torpedo station.

Medical Inspector G. F. Winslow, detached from the "Philadelphia" and granted three months' leave.

Surgeon J. A. Hawke, detached from the "Baltimore" and ordered to the "Philadelphia" as fleet surgeon of the Pacific station.

Asst. Surgeon A. Farenholt, detached from the "Baltimore" and ordered to the "Monterey."

Change of Address.

Hosmer, A. J., from Ashland, Wis., to 1811 Landau Gasse 13, Vienna, Austria.

Kereher, John, from 112 E. 18th to 104 E. 18th St., (Suffield Flats) Chicago, Ill.

Lincoln, D. F., from Geneva, N. Y., to 73 Pinckney St., Boston, Mass.

Miller, De Laskie, from 2419 Michigan Ave. to Virginia Hotel, Chicago, Ill.

Owsley, W. T., from Glasgow to Eastern Kentucky Asylum for the Insane, Lexington, Ky.

Roseberry, B. S., from Lacon, Ill. to El Paso, Texas.

ADDRESSES.

THE PRESENT ATTITUDE OF PHYSICIANS AND MODERN MEDICINE TOWARD HOMEOPATHY.

Presidential Address of the Medical Society of the State of Pennsylvania,
at its Meeting, May 22, 1895.

BY JOHN B. ROBERTS, AM., M.D.
PHILADELPHIA, PA.

The important relation of the physician to the community makes it seem proper to discuss before this audience, in which there are many non-medical persons, a question which is very imperfectly understood by those outside of medical circles. The public at large does not understand the position assumed toward homeopathy and homeopathic doctors, by those physicians who decline to accept all sectarian designations. Surprise is not infrequently expressed at the unwillingness of a non-sectarian physician to meet a homeopathic neighbor in medical consultation, though the social relations of the two may be most cordial.

This paper is an endeavor to show the causes of this apparent anomaly. Its most important aim is to hasten the time when all honorable persons engaged in preventing, alleviating and curing disease will refuse to be designated by adjectives implying, or seeming to imply, that they do not adopt every means or method of action that scientific investigation proves to be valuable.

He who treats disease by electricity, only, is properly called an electropath; he who uses water alone in all affections, a hydropath. The doctor who adheres to the homeopathic law of Hahnemann in all cases, is in a similar way properly termed a homeopath; and he who treated all of his patients by the law of allopathy, if there ever has been such a law formulated, would be an allopath. No allopathists exist; though some doctors have been so called, but not originally by themselves.

It must be clear to the least intelligent, moreover, that he who does not adhere to the special methods of treatment giving him his name, at once loses his logical connection with the designation. In other words, a practitioner who uses water or electricity, and also medicinal remedies according to the homeopathic law is no longer a hydropath or electropath. It is his exclusiveness of treatment in the one instance which gives him his title. His rejection of exclusiveness and his adoption of other means of treating disease rob him of his right to the sectarian name. It is apparent, therefore, that he who uses, or is willing to use, all remedies and all methods, and who varies the size of his dose, the character of the remedy and its method of application with the exigencies of the disease is neither electropath, hydropath or homeopath, but something broader. It may

be said, in passing, that by reason of his broadness he is perhaps better prepared to cope with disease.

Such practitioners as conscientiously choose their remedies and doses in accordance with the results of study and of experience with diseased processes, might with propriety be termed selective or elective physicians. The term would be applicable whether their actions were determined by their personal study and experience alone, or by the study and experience of others added to theirs. No such descriptive adjective is required, however, and the term "physician" suffices as does that of "dentist" in the sister profession; for common sense demands that he who would undertake any physical or intellectual work, should avail himself of every honorable means of accomplishment.

As all know, a medical sect called "eclectics" exists. The derivation of the name would seem to indicate that they select from all forms of remedies. They had originally certain ideas, I believe, as to the noxious qualities of remedies derived from the mineral kingdom, and advocated the use of vegetable remedies only. At any rate, the college established in Ohio in 1832 was the result of a resolution adopted, in order "that the people of the West may avail themselves of the advantages resulting from a scientific knowledge of botanic medication."¹ At present, the eclectics have, I believe, no special objection to mineral remedies. Dr. John M. Scudder, Professor of Practice of Medicine in the Eclectic Medical Institute, Cincinnati, says, "the eclectic gives remedies because their effect is *opposite* to or opposed to the diseased action. They may be selected according to the law of similia, or by empiricism, or by their known influence upon function and structure, physiologically or pathologically. They hold that remedies contain a *force* which set free in the body, influences its functions (mode of motion), doing that which is necessary to bring it back to that normal condition we call health."²

It is possible that the term eclectic was originally taken as a sectarian designation to create in the public mind the impression that eclectic physicians did differently, and did better, than those simply called doctors or physicians. Other medical sects have apparently done this for the purpose of attracting public notice. In many instances their chosen title has now no logical or etymologic connection with their belief or practice.

In this address I do not intend to discuss eclectic medicine at length; nor the beliefs and doctrines of vitopathists, physio-medicals, Thompsonians, and other sects. So far as I know, homeopathy is the only "school" or "sect" of medical practice under whose banner are enrolled any considerable number of physicians of intelligence and education.

¹ What is Eclecticism? A. J. Collins, p. 10.

² The Essential Differences between the Three Schools of Medicine, pp. 8-9.

It may be serviceable to ask the questions, What is medicine? What is homeopathy? Webster's unabridged dictionary defines medicine, homeopathy and allopathy as follows:

Medicine: "That branch of science which relates to the prevention, cure or alleviation of the diseases of the human body."

Homeopathy: "The art of curing, founded on resemblances; the theory and its practice that disease is cured by remedies which produce on a healthy person effects similar to the symptoms of the complaint under which the patient suffers, the remedies being usually administered in minute doses."

Allopathy: "The employment of medicines in order to produce effects different from those resulting from disease: a term invented by Hahnemann to designate the ordinary practice as opposed to homeopathy."

The Century dictionary gives similar definitions. Thus:

Medicine: "The art of preventing, curing or alleviating diseases and remedying as far as possible the results of violence and accident."

Homeopathy: "The medical treatment of diseased conditions of the body by the administration of drugs which are capable of exciting in healthy persons symptoms similar to those of the morbid condition treated."

A note is then added which says:

"In practice, homeopathy is associated with the system of administering drugs in very small, often infinitesimal, doses."

Allopathy: "In medicine, a therapeutic method characterized by the use of agents producing effects different from the symptoms of the disease treated."

A note goes on to say:

"The name is incorrectly applied, in distinction from homeopathy, to the traditional school of medicine, which opposes the homeopathic theory."

Eclectic medicine is defined by the Century dictionary as:

"A medical theory and practice based upon selection of what is esteemed best in all systems; specifically, the medical system of a separately organized school of physicians in the United States, who make much of what they regard as specific remedies, largely or chiefly botanical."

By these lengthy quotations it will be seen that there is a radical difference between homeopathy and medicine, in that the former is more limited in its meaning. Homeopathy is a method of treating disease and not the name of a branch of human science. It appears in these standard dictionaries in much the same manner as does evaporation or distillation in relation to chemistry. They are not sciences, but methods or processes of the science of chemistry, which may or may not be used by the professed chemist.

It may be asserted that this deduction from dictionaries is unjust toward the adherents of homeopathy. I can only reply that I have no knowledge of any medical dictionary written by a homeopathic physician, and that the non professional authorities quoted, are standard works of reference, whose attitude toward medical topics is unknown to me.

Medicine then comprises the art of preventing and treating disease; and is founded on biology, anatomy, physiology, chemistry and physics. All physical and physiologic laws are correlated with it, and to all such laws must it be subordinate. Its facts are only established by careful and painstaking observation and research. Medical hypotheses and theories must be subjected to the same rigid scrutiny and heartless criticism as the hypotheses, theories and suggestions of the physicist. The rules of evidence must be as stringently applied in determining the truth of alleged medical facts as they are in the

courts to ascertain the guilt or innocence of the accused.

It is evident, then, that medicine is a science and art, and is not electropathy, homeopathy or allopathy. It is equally clear that physicians who claim to study and practice the science and art of medicine are not allopaths, homeopaths or electropaths. Unfortunately, the general public does not realize this; and the majority of medical men are called allopaths, simply because they are not homeopaths. The error has been perpetuated by homeopathic literature giving the name allopath to those physicians who are unwilling to be homeopaths and who refuse to be affiliated with any sect of medicine. Homeopaths often speak in a similar way of homeopathy as the new school of medicine and describe non-sectarian physicians as of the old school. The difficulty of making the public understand the distinction between physicians and homeopaths has unfortunately led many physicians to carelessly and tacitly accept the designations "allopath" and "old school." Such terms, however, are not true. Physicians do not subscribe to a law of contraries or dissimilars (allopathy) as the homeopaths do to a law of similars.

The science of medicine can not be a sect or school any more than the science and art of navigation or agriculture. Physicians (often incorrectly called "old school doctors") are willing to use, and are never prevented by any code of ethics or society regulation from using, any remedy or dose which seems to them individually to be worthy of confidence. Ipecacuanha is given in minute doses for vomiting by many physicians, belladonna is used by them in scarlet fever, and aconite in many instances of fever, while phosphorus, bryonia, arnica, nitro-glycerin, etc., are remedies often used.

These and all remedies are used by non-sectarian physicians because physiologic and chemic study or experience has shown them to be indicated. The homeopathic physician uses them because he believes they produce, in the well, symptoms similar to those with which his patient is afflicted. For example, the homeopathic doctor gives a dilution of ipecacuanha containing an exceedingly minute amount of the drug to relieve vomiting; because ipecacuanha in doses of several grains causes vomiting in the healthy. The method of employing ipecacuanha by the non-sectarian rests on an entirely different basis. He gives small doses of the drug—not exceedingly minute amounts—when his patient has nausea due to a catarrhal condition of the stomach and bowels; because science has taught him that small doses of ipecacuanha stimulate and render less viscid the secretion of the mucous membrane of the stomach, increase the secretion of bile by the liver and promote digestion. His use of ipecacuanha has no relation or connection with the fact that larger doses cause vomiting. In some instances the drug employed is called by a name different from that adopted by the homeopaths, because physicians use the name adopted by the United States Pharmacopoeia, the official guide in such matters published every ten years by a convention composed of delegates from the United States army, navy and marine-hospital service, the medical colleges and societies of the Union.

Again, physicians who are not homeopaths prescribe medicine in the form of powders, and at times put a few drops of a strong tincture, or a small pellet or tablet, into a tumbler partly filled with water, and

direct a teaspoonful to be taken at definite intervals. These methods which seem to the public to be inseparably connected with homeopathy, are also used, therefore, by non-sectarian doctors.

Medicine requires its votaries to examine into the hypotheses and theory of drug action and the causation of disease, and to accept as true only those statements which can stand the test of accurate scientific investigation. Many are the theories and beliefs that have been over-turned by the searching criticism thus given.

Medicine is ever ready to receive with open arms that which promises increased power against disease; but before it is accepted as truth it must show that it can stand the rigid test of modern science. The assertion of no man, or body of men, however eminent or revered, is accepted as final. Truth can not be predicated upon the statement of a few. The fact is only provisionally accepted until the accumulated proof of many diverse investigators and observers makes its truthfulness almost a certainty.

The public doubtless remembers the rejection of the Brown-Séquard elixir of life and the tuberculosis cure of the renowned Koch. The eminence of these men gave unusual importance to their assertions, but did not stay the critical study which showed the error of their beliefs. On the other hand, the germ theory of disease propounded by Koch has constantly been adding to the number of its converts, until now it is accepted by the major part of the medical world.

This review shows that non-sectarian medicine does not prohibit a physician holding views different from those of his fellows on questions of drugs and treatment. Its only demand is that its followers be catholic; that is, broad and open to conviction in all directions; that they approach all subjects in a truly scientific and humanitarian spirit. For this very reason, however, it does, from its essential nature as a science, prohibit that sort of exclusiveness which says that only one law or dogma can be true and correct.

He who says that "so and so" is the only universal law, at once reveals an unscientific spirit and mind, and precludes the personal investigation and observation which is necessary to make him a rational follower of scientific medicine. I may perhaps make myself clearer by an illustration. A civil engineer who believes and acts on the belief that the only and universal method of bridging a river is by the erection of wooden truss bridges is not a rational and scientific civil engineer. He is a "wooden-truss bridge builder," if you choose, but he is not and can not be, a scientific civil engineer, because the experience and observation of the great mass of competent observers show that streams may be bridged by truss bridges of iron, suspension bridges of wire and bridges with stone arches.

It was this exclusiveness in the methods of treatment proposed by Hahnemann, and adopted by his immediate followers, under the name homeopathy, that separated the homeopaths from the ranks of those who believed, and who still believe, in the use of any and all methods *proved* to be curative. Non-sectarian physicians hold to no exclusive dogma or doctrine in therapeutics, and believe that Hahnemann was in error in his opinions that "like cures like" and that drugs are increased in power by trituration and shaking. They believe that the doses advocated

by him were so infinitesimally small that they are inert. Dr. H. B. Hemenway says³ that he has several times examined low dilutions, not high dilutions, of *mercurius vivus* prepared by one of the most reliable homeopathic drug firms in the country, without finding the slightest trace of mercury.

In other words, they believe that experience and scientific investigation have shown and do show, that the cures attributed to these exceedingly small doses are instances of erroneous observation, that the cures occurred in fact without any curative effect being exerted by the drugs. They believe that it is contrary to the lessons of the science of medicine and of collateral sciences that 150 cases of true scarlet fever could be treated without a death by medicines of the two hundredth and higher homeopathic potencies exclusively.⁴ They doubt the accuracy of the observations of Dr. William Ray of England who in a cholera epidemic "had splendid success" with the two hundredth potency of camphor.⁵ They feel hesitancy in accepting as true, the statement that common table salt can be so changed by the homeopathic method of trituration and administration that it "will cure more cases of intermittent fever than any other known remedy." Yet a homeopathic author says: "With the thirtieth dilution I have cured several hundred cases with this drug alone."⁶

Without presuming to question the honesty of opinion of these authors, non-sectarian doctors believe that knowledge, possessed by the general public, is sufficient to cause distrust in the scientific accuracy of these observations and statements.

Much of the evidence given by Hahnemann and his early followers on the law of similars (*similia similibus curantur*, as he puts it) is open to the same criticism as to accuracy. Until rigid scientific investigation proves the truth of Hahnemann's law of similars and his doctrine of potentization and dynamization of drugs in almost infinitesimal doses, the physician who believes in the scientific character of medicine is compelled by logical reasoning to class Hahnemannism and homeopathy with Brunonism, Bronssaisism, Humoralism, Solidism, and the other systems, schools or sects of medicine, which have long fallen under the ruthless knife of scientific research. These were also speculative and founded on the deductive system of reasoning.

If the truth of Hahnemann's propositions are ever scientifically demonstrated, they will accept them as heartily as many of them do. Dr. Koch's recent demonstration of the connection of consumption with the tubercle bacillus, and as most of the world does Jenner's assertion that vaccination protects from smallpox.

An apparent demonstration of the erroneous character of Hahnemann's teaching is the fact that many physicians who are classed as homeopaths do not believe in the small doses advocated so strenuously by Hahnemann, nor in the universality of the homeopathic law of similars. I call these gentlemen homeopaths because they teach in homeopathic colleges and belong to homeopathic societies; and thereby accept the designation.

It is not to be wondered at, then, that physicians at large can not accept homeopathy, when even Hahne-

mann's avowed followers give evidence in their practice and writings of their defection from his teachings.

Two years ago I gave in an address⁷ evidence of this defection of homeopathic physicians from the doctrines of Hahnemann. At this time I shall only record the statement of Dr. Jabez P. Dake, a high authority in the homeopathic school, made in 1894 at the meeting of the American Institute of Homeopathy. In an article entitled, "What the Homeopath should know of Drugs,"⁸ he says:

"We can not imagine a physician who is entirely limited to the homeopathic use of drugs." In speaking of the symptoms produced by drugs, detailed, by the votaries of homeopathy, after "provings," he says: "It is a lamentable fact, shown indisputably by the higher medical criticism, that the sources of impurity, the gateways to the realms of imagination, misapprehension, and even fraud, were not all shut while the drug pictures were being taken. Applying all the rules of evidence to the witnesses whose testimony constitute our materia medica, we must realize that very few of them have come up to the standard requiring the 'the truth, the whole truth, and nothing but the truth,' concerning drug effects."

It is this aspect of the case which prevents the members of this society and other non-sectarian physicians believing in the scientific accuracy of many of the observations recorded in homeopathic works.

If homeopaths themselves do not believe in the general accuracy of the statements in Hahnemann's "Materia Medica Pura," Jahr's "Manual" the "Encyclopædia of Pure Materia Medica" and the "Cyclopædia of Drug Pathogenesis," it is not surprising that others can not bring themselves to believe in the universality or infallibility of the homeopathic law.

Samuel Hahnemann was born in Germany in the year 1755 and died in 1843. He founded the homeopathic school of medicine, which is the only school, system or sect of medicine of any importance at the present time. The vitapathist, vita-chemical, physio-medical, eclectic and Christian science schools are less important. The adherents and quasi-adherents of homeopathy probably exceed in numbers the adherents of all the other sects of medicine taken together. This is partly due to the circumstance that many practitioners who are classed with homeopaths are really practitioners of rational or scientific medicine, with a belief in the truth of some, but not all, of Hahnemann's teachings. They are the subject of bitter denunciation by those who still accept homeopathy in its entirety.

Dr. John C. Morgan⁹ complains greatly of the prevalent neglect in teaching homeopathy in homeopathic colleges. He says that some instruction is given to the freshman classes; but that "if the second, third and post-graduate years had been planned for this obliteration of Hahnemannism the result could scarcely be more complete."

This inattention to homeopathy in the colleges of that school seems to be due to the fact that the great mass of their teachers have little faith in the principles insisted upon by Hahnemann. They have apparently seen the defect of the homeopathic law, but are not yet willing to disavow a belief in its infallibility and universality.

Haller, who died in 1777, when Hahnemann was still a young man, may be said to be the father of the modern science of medicine. He rejected all theorizing on medical topics and all attempts to find laws of treatment or found systems or schools of medicine. He argued that rational or scientific medicine could only be reached by exact and critical study of anatomy, physiology, pathology, and the effects of remedial agents on the functions of the body.

The claim that Hahnemann first formally enunciated the doctrine that remedies should be studied by administration to healthy persons seems to be untrue, as Haller preceded him in this assertion. Hahnemann is said to have divined or discovered the homeopathic law of similars, as it is called, about 1790. It was probably not entirely new.¹⁰

It has been truly said¹¹ that rational or scientific medicine began its life when Albrecht von Haller recognized the fact that "the laws of nature are not things which we can evolve by any speculative method. On the contrary, we have to discover them in the facts; we have to test them by repeated observations and experiments. In proportion only as they hold good under a constantly increasing number of cases, and in the greater delicacy in the means of observation does our confidence in their trustworthiness rise."

Hahnemann's first doctrine was the so-called law of Nature "*similia similibus curantur*"—like things are cured by like things—which he describes as a "law until the present time, although it has on all occasions formed the basis of every visible cure."¹²

This law of similars is the basis of his system which he called homeopathy from two Greek words, signifying "similar" and "suffering" or "disease." It is strange that while he in some places speaks of the law being first taught by himself, he, in other parts of the Organon, admits it was not without previous advocates.

The second doctrine of Hahnemann's system is that dilution of drugs increases their curative power. The potentization or dynamization of drugs, as this increase of power in diminishing quantities is called, is accomplished by taking one part of sulphur, for example, and rubbing or triturating it with ninety-nine parts by weight of sugar of milk. This is the first trituration, designated the first potency. One part of this sulphur mixture is then triturated in a similar manner with ninety-nine parts of sugar of milk, constituting the second trituration or potency. This process may be continued indefinitely, though Hahnemann considered that the best results were obtained, and the most "dynamic power" developed in the thirtieth potency or attenuation.

In the case of liquids, such as tincture of aconite, two drops of the "mother tincture," made of equal parts of expressed juice and alcohol, were mixed and shaken up with ninety-eight drops of alcohol to make the first potency, and successive additions of ninety-nine drops of alcohol were made to one drop of this first potency in a manner similar to that used with solid drugs.

It was necessary, according to Hahnemann, "not to rub or shake the drugs too much, or they might become too strong." He says: "Homeopathic medicines acquire, at each division or dilution, a new

degree of power by the rubbing or shaking they undergo, a means of developing the inherent virtues of medicines that was unknown until my time, and which is so energetic that latterly I have been forced to reduce the number of shakes to two, of which I formerly prescribed ten to each dilution."¹³

In the American Homeopathic Pharmacopœia of 1886, those interested will find detailed accounts of the various methods of preparing homeopathic remedies. The decimal scale of potentiation, introduced by Dr. Constantine Hering and now a good deal used, will also be found there described. Hering's decimal scale is distinguished from Hahnemann's centesimal scale by placing an *x* after the number of the potency; thus, "2*x* potency."

In order that liquids should not be shaken too much and made too strong, Hahnemann directed that, after the dilution was made to the potency desired, small globules of sugar of milk should be saturated with the solution. These would have the desired curative power, which would not accidentally be increased by shaking. The shaking is best performed by moving the arm from above downward; and if properly performed, imparts active medicinal virtue to substances usually regarded as entirely or almost inert. Pure carbon, flint, table salt and similar substances are by proper dilution made powerful curative remedies.

The belief of the author of homeopathy in his system is shown by these words: "The most violent pleuritic fever, with all its attending alarming symptoms, is cured in the space of twenty-four hours at the farthest, . . . by giving one globule of sugar impregnated with the juice of aconite of the decillionth (thirtieth) degree of dilution."

In cases of overloaded stomach "the patient should 'smell once' a globule of sugar the size of a mustard seed, impregnated with the thirtieth dilution of pulsatilla," and be "infallibly cured in the space of two hours."

Hahnemann's next "great truth, which remained concealed from all my predecessors and contemporaries," is that all diseases, except two, owe their origin to a "chronic miasm" which had descended through many generations of men from the itch (psora). His statement is:¹⁴ "This psora is the sole, true and fundamental cause that produces all the other countless forms of disease which, under the name of nervous debility, hysteria, hemiplegia, hypochondriasis, insanity, melancholy, idiocy, madness, epilepsy and spasms of all kinds, softening of the bones, or rickets, scoliosis and kyphosis, caries, cancer, fungus, hematodes, pseudo-morphæ of all kinds, gravel, gout, hemorrhoids, jaundice and cyanosis, dropsy, amenorrhea, gastrorrhagia, epistaxis, hemoptysis, hematuria, metrorrhagia, asthma and phthisis ulcerosa, impotency and sterility, deafness, cataract and amaurosis, paralysis, loss of sense, pains of every kind, etc., appear in our pathology as so many peculiar, distinct and independent diseases."

Another of the principles of homeopathy was that no two medicines should be administered at the same time. A single drug in an infinitely small dose is the only medication allowable.

Some homeopaths believe that in chronic diseases a single dose of a homeopathic remedy may cure. Dr. J. C. Morgan, for example, asserts that "Some-

times, as in tumors, a single dose, once in thirty days, as of sepia or hepar sulph., has done¹⁵ good 'alterative work.'"

The desire to obtain "similars" has led some homeopathic physicians to employ unusual remedies from the animal kingdom. Dr. Morgan in the paper above quoted makes this assertion: "Dr. Samuel Freedley informed me of his curing himself of an 'old man's ulcer' of the leg by tarantula cubensis. I reasoned that an animal so low represents degraded human tissue, and is homologous with low disease changes. Hence I have used cimex with benefit in ulcer of the rectum. . . ." The tarantula cubensis is a large spider of the West Indies; the cimex is the well-known bedbug.

The American Homeopathic Pharmacopœia published in 1883 by Boericke & Tafel shows¹⁶ that the cimex or bedbug is made for homeopathic practitioners as follows: "The live insect, crushed, is covered with five parts by weight of alcohol. Having poured the mixture into a well stoppered bottle, it is allowed to remain eight days in a dark cool place, being shaken twice a day. The tincture is then poured off, strained and filtered. Amount of drug powder one-tenth. Dilutions must be prepared as directed under Class IV."

The medicine called by homeopaths "blatta Americana" is prepared from the great American cockroach. In this case "the live animal is crushed and triturated, as directed under Class IX."¹⁷ In preparing "mephitis" one part by weight of the characteristic fluid expelled by the polecat or skunk is dissolved in ninety-nine parts by weight of alcohol.¹⁸ Variolinum is prepared by Boericke & Tafel for homeopathic uses¹⁹ by triturating the contents of a ripe smallpox pustule as directed under Class VIII. Psorinum was introduced as a medicine by Dr. Constantine Hering,²⁰ who says: "I collected the pus from the itch pustule of a young and otherwise healthy negro. . . . I opened all the mature, unscratched pustules for several days in succession, and collected the pus in a vial of alcohol. After shaking it well and allowing it to stand, I began my provings with the tincture on the healthy. . . . I administered it to the sick with good results, and sometimes witnessed aggravations."

Dr. Samuel Swan, who deals in homeopathic remedies in high potencies in New York, says in his catalogue:²¹ "In order that all should have the benefit of high potencies, the plan of sending grafts has been adopted; if a graft is put in a vial of any size and the vial filled with unmedicated pellets and corked, the whole will be medicated in half an hour." He indicates on the same page of this catalogue that when a vial of medicine is nearly emptied, the physician can fill it up with unmedicated pellets, which will become medicated by being in company with the pellets previously contained in it; thus presumably acting in a manner similar to the grafts spoken of in the paragraph quoted above. He says: "You will not have to purchase the remedy a second time."

Among the remedies advertised are: "Pus from rectal abscess." "Pus from caries of os calcis." "Pus

from septic abscess" (p. 21). "Vomito; blood from a yellow fever patient while moribund." "Sal cerebri; salt secreted profusely from a gentleman's scalp, with the perspiration, and on drying it was crystallized so heavily his head looked frosted" (p. 30). "Pediculus capitis," "Pediculus corporis, from Boston" (p. 20). "Tinien syphilitica, syphilitic patient with tinea capitis" (p. 25). "Luna (moonlight)" (p. 16). "Helios, the sun" (p. 13). "Omnia" (p. 29).

I do not know the standing of Dr. Swan as a homeopathic pharmacist, but the fact that his catalogue has reached its second edition would seem to indicate that he is patronized by homeopathic physicians. He does not state in what diseases "moonlight" or "pediculus corporis" (body louse) "from Boston" are employed by homeopaths.

To determine for what diseases the several drugs are cuative, it was, of course, necessary to find out what symptoms the drug produced in a healthy human being. Therefore an infinitesimal dose of the substance to be proved was taken by a healthy person, preferably a physician, who then noted, once, twice or thrice a day, the sensations and occurrences he found in himself for a period of several days. These symptoms, called the pathogenesis of the drug, were recorded in catalogue form. Each drug so proved has many pages of symptoms recorded.

The real homeopathic physician, who has a sick man to treat, looks over this list of drug symptoms, and administers an infinitesimal dose of a single drug which is found in the table to produce symptoms "similar" to those presented by the patient. For example, a drug which has produced symptoms pertaining to the head is to be given to a patient presenting "similar" but not "identical" head symptoms.

Dr. Berridge, an ardent homeopath, relates²³ a case of congestion of the brain, and condemns the homeopathic doctor who stopped giving arnica because, as he said, "he did not believe it acted on the head more than on the big toe." The argument of Dr. Berridge is that the doctor was too ignorant to know that "Allen's Encyclopedia gives seven symptoms of arnica belonging to the big toe and nearly one hundred belonging to the head."

I mention this to show the reader how homeopathy undertakes to cure disease. The changes in the fluids and the alterations in the tissues of the body are not to be investigated for the purpose of discovering the cause of the patient's disease. His symptoms are to be noted and then a search made among the lists of "proved" drugs for one that induces similar symptoms. A recent paper published in the *Hahnemannian Monthly*, February, 1894, by Dr. Joseph C. Guernsey is entitled, "Symptoms, the Basis of Homeopathic Prescribing," and illustrates the method I have described.

The skill which makes one homeopath better than the other, lies in "selecting the remedy" or "*similimum*" which most nearly simulates the symptoms. The remedy whose drug effect corresponds most nearly with the greatest number of disease-effects in the patient is believed to be the most certain cure. Herein lies the difference between the successful and the unsuccessful homeopathic physician, according to the doctrine of homeopathy.

Many devices have been employed by homeopaths to aid in "selecting the remedy" from the multitudinous lists of symptoms found in their text-books.

Boenninghausen's "Therapeutic Pocket-Book," Jahr's "Symptomen-Codex" and "Repertories" are the refuge of the true Hahnemannian. Dr. Morgan, for example, tells us²⁴ that he once sought a remedy for a case of intermittent fever, with chill beginning on the right side. Taking Jahr's "Symptomen-Codex," he examined the "fever" rubric of every drug, and found under Rhus tox., "the left side of the body felt hot, and the right side cold," etc. Examining for the other symptoms, pain, etc., this drug was found to have all of them; and Rhus tox. was then known to be the remedy. The same author describes the "numerical method" of finding the remedy thus: "Its most salient expression is found in Dr. W. J. Guernsey's "Boenninghausen." In this the rubrics of the "Therapeutic Pocket-Book" are printed upon separate long strips of stiff paper, with the rank of each drug thereunder, 1, 2, 3, 4, in numerals. Selecting the slips containing the various symptoms, they are placed side by side upon a table; then each drug, beginning with those of highest rank, is counted by adding all its printed numerals together. The one having the highest number is held to be the *similimum*, irrespective of the claims of keynotes, etc.

Homeopathy, therefore, lays no stress upon the importance of the study of physiology and pathology. Hahnemann says: "I can not comprehend how it is possible for physicians to imagine that they ought to search the interior of the human economy."

Some doctors, still calling themselves homeopaths, reject many of these doctrines of Hahnemann; but in so doing seem to be no longer homeopaths.

There are still in the ranks of homeopathy, however, those who believe in the universality of the law of similars and the potentiation of drugs by trituration and shaking. E. W. Berridge, for instance, shows by the following words his belief that the homeopathic law of similars is unfailing: "We, however, never give medicines for the cure of disease on any other law than that of similars, and have never any occasion to do so."²⁵ The statements in this quotation are Dr. Berridge's, not mine, and show the earnestness with which he makes the assertion that the law of similars is in his mind a universal therapeutic law.

Dr. Neidhard uses the words,²⁶ "If this fundamental law can be overthrown, then homeopathy, as a science, is as good as lost. If it is not a universal law of cure that will shorten the natural course of diseases, that will mitigate more permanently the pains of disease than any other method of cure, it will not deserve our respect nor our study." He says also that from the time of Hippocrates, and, as far as any records are left from the beginning of all times, all true cures of diseases were always performed according to the homeopathic law.²⁶

He, on page 7, illustrates the working of this law of similars by citing the case of two ladies who were entirely exempt from seasickness at sea because they were previously subject to chronic sick headache with nausea and vomiting. The same author (p. 10) shows his belief in infinitesimal doses by reporting the account of a number of men who escaped cholera during an epidemic because they were engaged in making and selling copper articles. Copper,

²³ Loc. cit.

²⁴ Homeopathy Vindicated, Liverpool, 1879, p. 38.

²⁵ Universality of the Homeopathic Law of Cure, by Charles Neidhard, M.D., Philadelphia, 1871, p. 1.

²⁶ Idem, p. 5.

it must be recollected, is believed by the homeopathic school to be a medicine of superior efficiency in cholera.

Dr. Neidhard likewise administers (p. 10) small doses of rattlesnake venom to destroy the appetite for liquor, because "whisky in large quantities is a well-known frontiersman's remedy for the bite of the rattlesnake and is often successful." Further illustrations or proofs of the universality of the law of similars are given by the same author as follows (Id. p. 12). "A friend throwing some flowers, withered by a hot July sun, into a basin of warm water found them, some hours after, to his astonishment, as fresh as ever, completely revived."

"The best thief catchers and detectives are those who formerly have been engaged in the same business—that is, have been thieves."

"Disappointed love can cause consumption and rheumatism, but when you have it, it may also cure it—a true homeopathic cure" (Id. p. 13).

The homeopathic law is, according to Dr. Neidhard (p. 21), operative in education. He says: "A vicious boy who pokes his umbrella into everybody's side is cured by letting him stand in a corner with an immense umbrella over his head until he is tired."

Dr. J. C. Guernsey says: ²⁷ "If a remedy fails to act, after giving it in a potency sufficiently high to warrant a fair trial, we may make up our minds that we have not found the *similimum*, i. e., we must blame ourselves and not the law *similia similibus curantur*."

Dr. J. H. McClelland says: ²⁸ "In the homeopathic law, internal medicine has reached finality."

The *Organon*, a homeopathic journal of Liverpool, England, published some years ago (April, 1878) a "Declaration of Homeopathic Principles," signed by nearly one hundred and fifty homeopathic physicians, nearly all of whom were practicing in America. The first essential point of the homeopathic doctrine is given thus: "The cure of the sick is most easily, mildly and permanently effected by medicines that are themselves capable of producing in a healthy person morbid symptoms similar to those in the sick." Another essential point is: "Local treatment of all kinds in *non-surgical* cases is not only unnecessary, but is apt to change the location of the disease and induce dangerous complications, and never *permanently* cures."

The non-sectarian doctor does not understand the position of these homeopathic physicians on the subject of the numerous skin diseases that are so quickly cured by mild local measures. They are certainly cured permanently, and just as certainly are not surgical cases.

The above declaration appears to have been prepared by Dr. Adolph Lippe, of Philadelphia, who states that among homeopathic physicians "the departure from Hahnemann's teaching have rapidly multiplied." (Reprint, p. 5 and 7.) Hence the necessity for the preparation and publication of the "Declaration of Homeopathic Principles"; for in his opinion: "We must be governed by *infallible principles* and not by the *opinions of fallible men*." Dr. Lippe goes on to show that homeopathy allows no deviation from the homeopathic law, and indicates that the homeopathic physicians and homeopathic societies that approve of such liberality are not truly homeopathic.

Dr. James B. Bell, President of the International Hahnemannian Association, in his address delivered in June, 1892, said: ²⁹ "Our society numbers in active living members about one hundred and fifty, and it would be a generous estimate, I think, to double that number, as representing in the whole world all those who may called true Hahnemannians, or who are becoming such. If we have patients going to other cities, especially in the West and South, how rarely can we recommend a physician to them, and if the patients are going to Europe or England, we know of but five or six men in the great cities to whom we can safely intrust them."

Until the recent establishment in the United States of medical examining and licensing boards it was practically impossible to determine the relative numerical strength of the homeopathic profession. In many States, all physicians have to pass a medical examination before being given a license to practice. Homeopathic physicians have insisted upon having a separate examination, and it thus has become possible to compare accurately the numbers of non-sectarian and homeopathic practitioners. In New York during 1892, 1893 and 1894, 713 applicants for license appeared for examination before the non-sectarian board of examiners, 80 applicants before the homeopathic board and 15 before the eclectic board. ³⁰ In Pennsylvania during the year ending March 1, 1895, there were 331 non-sectarian applicants, 56 homeopathic applicants and 12 eclectic applicants. ³¹ The Illinois State Board of Health shows in its Report on Medical Education of 1894, that in 1893 there were graduated from the medical colleges of the United States and Canada 425 homeopathic physicians and 4,975 non-sectarian physicians. The number willing to graduate from homeopathic schools would seem by these figures to be about one-eleventh of those graduating from the non-sectarian schools. If the President of the International Hahnemannian Association, quoted above, is accurate in his statement, the relative proportion of real followers of Hahnemann is much less.

The attitude of modern medicine and its votaries to homeopathy and homeopathic physicians will be readily understood after this survey of the principles of homeopathy based on the writings of Hahnemann and his disciples. Non-sectarian physicians believe it is a duty to the patient that the doctor shall use every means of cure which seem to hold out a prospect of benefit. To limit himself to "similars," or to decline to use "local treatment of all kinds in non-surgical cases" because it "never permanently cures" seems to such physicians unjust in the one case and not in accord with practical experience in the other. To subscribe to a law of "similars," a law of "dis-similars" or to any other dogma of treatment and say that it is "infallible" and "universal" appears to him unscientific and a step sure to lead to harm to the sick man. He feels that he must have the whole world of science, medical and collateral, from which to draw; that he must have a right to use any remedy in any dose or form that seems to him good; and that he similarly must have a right to decline to prescribe according to any law if he have no faith in the law.

The refusal of most non-sectarian physicians to meet homeopathic physicians in consultation over

²⁹ The Homeopathic Physician, Philadelphia, August, 1892.

³⁰ New York Medical Record, May 4, 1895.

³¹ Compiled from statement received from Medical Council of Pennsylvania.

²⁷ Hahnemannian Monthly, February, 1894, p. 82.

²⁸ Jubilee Address before American Institute of Homeopathy, 1894, p. 47.

cases of disease, is based on the *exclusiveness* of homeopathy. So long as the homeopathist believes in the exclusive dogma that "like cures like" and is therefore debarred from using remedies and methods and doses which do not conform to that law, the non-sectarian physician feels unwilling to consult with him, because the homeopathic doctor would be prevented from using any and every drug and method. Hence, the hands of the non-sectarian doctor would be tied and the consultation would not give the patient all the advantages that ought to be at his service.

This is the position that has long been taken by the AMERICAN MEDICAL ASSOCIATION, the representative of the non-sectarian medical profession of the United States, and its affiliated State medical societies and county medical societies. The Code of Medical Ethics of the AMERICAN MEDICAL ASSOCIATION in Art. IV, Sec. I, says:

"But no one can be considered as a regular practitioner or a fit associate in consultation, whose practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology and organic chemistry."

The following explanatory statement was adopted by the ASSOCIATION about twelve years ago:

WHEREAS, Persistent misrepresentations have been and still are being made concerning certain provisions of the Code of Ethics of this ASSOCIATION, by which many in the community, and some even in the ranks of the profession, are led to believe those provisions exclude persons from professional recognition simply because of differences of opinions or doctrines, therefore

1. *Resolved*, That clause first, of Art. IV, in the National Code of Medical Ethics, is not to be interpreted as excluding from professional fellowship, on the ground of differences in doctrine or belief, those who in other respects are entitled to be members of the regular medical profession. Neither is there any other article or clause of the said Code of Ethics that interferes with the exercise of the most perfect liberty of individual opinion and practice.

2. *Resolved*, That it constitutes a voluntary disconnection or withdrawal from the medical profession proper, to assume a name indicating to the public a sectarian or exclusive system of practice, or to belong to an association or party antagonistic to the general medical profession.

3. *Resolved*, That there is no provision in the National Code of Medical Ethics in any wise inconsistent with the broadest dictates of humanity, and that the article of the Code which relates to consultations can not be correctly interpreted as interdicting, under any circumstances, the rendering of professional services whenever there is a pressing or immediate need of them. On the contrary, to meet the emergencies occasioned by disease or accident, and to give a helping hand to the distressed without unnecessary delay, is a duty fully enjoined on every member of the profession, both by the letter and the spirit of the entire Code.

As soon as a homeopathic physician asserts that he is willing to give any drug in any dose and to use any method of treating disease that holds out a reasonable prospect of benefit, and states that he is not bound to practice *exclusively* according to the homeopathic law of similars, he becomes eligible for membership in the AMERICAN MEDICAL ASSOCIATION, and the State and county societies connected with it. There are thus at the present time, quite a number of physicians connected with the AMERICAN MEDICAL ASSOCIATION and its constituent societies, who previously were considered and considered themselves to be homeopaths. As will be readily understood from the Section from the Code of Ethics, above quoted, such gentlemen are no longer considered undesirable physicians to meet in consultation.

As has been stated in the earlier part of this paper, a very large proportion of the graduates of homeopathic colleges no longer believe in the infallibility of the law similars, and do not restrict their practice

to treating diseases according to its principles. All such physicians become eligible for membership in the AMERICAN MEDICAL ASSOCIATION and in the society which I now address, by the simple statement that they do not believe in the infallibility of Hahnemann's law, and who constitute, according to Dr. Bell, a very small proportion of the physicians considered by the public to be homeopathists, would not be eligible to membership in the AMERICAN MEDICAL ASSOCIATION, or similar organizations of physicians, because they believe and practice according to an exclusive dogma.

Those graduates of homeopathic colleges and members of homeopathic societies, who admit that the law of similars is sometimes fallible, seem to be unwilling to publicly assert their modified belief in Hahnemann's teachings. By permitting themselves to be called homeopathic physicians by the public, though really not practicing according to Hahnemann's law (except in a proportion of their cases) they seem to be using the name "homeopathist" for the purpose of making the public believe that they are in some indefinite way different from all other physicians; and that they possess powers different from those possessed by physicians who do not accept the designation, "homeopathist." Non-sectarian physicians look upon this assumption of a special title as derogatory to the votaries of any science.

This is the reason that homeopathists are sometimes referred to as doctors who assume a sort of trade-mark for the revenue that may be derived from such a designation. Hence, many non-sectarian physicians contend that a man graduated from a homeopathic college, or publicly professing to practice homeopathy, should not be considered worthy of being met in professional consultation unless he publicly disclaims the title "homeopathist," and asserts that he is willing to practice by other methods as well as those prescribed by Hahnemann.

Dr. Solomon Solis-Cohen states³² his position thus: "If, however, one whose personal character fits him for membership in this society, but who had formerly professed homeopathy, becomes convinced of his mistake, and desires to join the ranks of scientific medicine, he should be freely received; provided only that he repudiates any sectarian designation and gives to the censors satisfactory evidence of his professional attainments. More than this we ought not to ask. Less than this we can not honorably accept."

A considerable proportion of the non-sectarian profession, however, is of the opinion that it is unreasonable to expect men who have been associated with homeopathic colleges and societies to make such a public disclaimer. They think it should be sufficient for such gentlemen to show by their actions that they do not believe in the infallibility of Hahnemann's law; that the very fact that they use methods of treatment founded on anatomy, chemistry, physiology and pathology, should be sufficient to entitle them to join the AMERICAN MEDICAL ASSOCIATION and similar professional organizations.

This is the view of a recent correspondent of the *Medical News*, whose name I do not know, who says: "If they were allowed to come into the regular societies without going down on their knees and confessing that they have been sinners, and being forced to renounce their previous faith, they would

soon after admission stop preaching homeopathy, as they became accustomed to their new positions, with that gradual change of mind that good fellowship produces. The majority of them now do not practice homeopathy, but they are forced to preach it in self-defense."³³

The attitude of physicians and modern medicine to homeopathy, then, is that assumed by these two classes of non-sectarian physicians, namely, those who insist that the homeopathist must make a formal public disclaimer of exclusiveness; and those who think it sufficient that he should simply indicate in any way that he is willing to treat patients by any drug, dose or method, that seems to him to be worthy of confidence in the treatment of disease.

The New York State Medical Society has publicly proclaimed itself of the opinion that a physician should be free to consult with any other doctor who seems to him personally to be worthy and likely to be of service in the treatment of the patient under consideration. This action caused the formation of a new State medical organization by those non-sectarian doctors of New York, who believed that homeopathists should make a formal disclaimer before becoming eligible for professional consultation. This society is called the New York Medical Association. No action similar to that of the New York State Medical Society has been taken by any other State medical society or by the AMERICAN MEDICAL ASSOCIATION; but a considerable proportion of the membership of these organizations seem to believe that the action of the New York State Medical Society should be followed; I do not know of any member of the AMERICAN MEDICAL ASSOCIATION refusing professional recognition to members of the New York State Medical Society since it took the step mentioned. It is probable that in a few years the world will see most physicians consulting with those homeopathic graduates, who are willing to treat patients by any and all drugs, doses and methods, without demanding of a formal recantation of their former belief in the exclusiveness and infallibility of Hahnemann's law of "similars."

Much of the instruction received by students in homeopathic colleges at the present time is identical with that given in non-sectarian medical schools. That this is well known is evident from the fact that the Association of American Medical Colleges has passed by-laws permitting those who have received instruction in homeopathic schools to advanced standing in the colleges belonging to the Association³⁴.

The Woman's Medical School of the Northwestern University, at Chicago, admits to the senior class graduates of homeopathic and eclectic medical colleges who "have taken considerable post-graduate work³⁵ on the same terms as graduates of non-sectarian medical colleges. This action is especially significant, because Dr. N. S. Davis, an ex-president of the AMERICAN MEDICAL ASSOCIATION, is one of the Trustees of the University; and two members of the Faculty (Drs. D. W. Graham and E. Fletcher Ingals) are Trustees of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

MEDICAL ASSOCIATIONS AND IDEALS.

Retiring President's Address before the Denver and Arapahoe Medical Association.

BY J. N. HALL, M.D.

PROFESSOR OF MATERIA MEDICA, THERAPEUTICS AND CLINICAL MEDICINE
IN THE UNIVERSITY OF COLORADO.
DENVER, COLO.

In retiring from the chair I wish to thank the members of this society, for myself and my brother officers, for the cordial support which has been accorded us during the year. As the custom of the society requires that the President shall make some remarks upon laying down the gavel, I shall ask you to consider with me the relations of physicians to medical societies, their duties toward them and the advantages to be derived from membership in them. The function of the medical school is to teach anatomy, pathology, medicine and surgery, and the other branches which go to make up a physician's education. But the graduate, with this knowledge, is not all that a physician should be, for there are many things yet for him to learn before he can become a polished member of the profession. Where the medical school leaves off the medical society should begin, that the young practitioner may absorb, may imbibe from his fellows the things which the school can not teach—the traditions, the ethics, the etiquette, the high ideals which make our profession, not a trade, but a liberal profession, which has come to us in its present shape because enriched by the labors of our predecessors for more than two thousand years. If the physician is to add anything to the knowledge of his guild, and he can not pay the debt he owes to the profession unless he does, he must have high ideals. As the stream does not flow higher than its origin so, in our craft, good work can not come unless the inspiration is drawn from a high source.

If you note in your morning paper that, in Montana, or Alabama, or Maine, a horse has trotted a mile in two minutes and ten seconds, you may wager with almost absolute certainty of winning, that there flows in his veins the blood of Darley's Arabian, or the Byerly Turk, or the Godolphin Arabian, for the reason that no horse ever trotted a mile in that time unless he sprang from the great English thoroughbred race, which, in turn, sprang from the sources indicated. Nurtured for two hundred years by the most skillful breeders of England, this race has given origin to the fast horses of every country where modern civilization holds sway.

In analogous manner we may trace the origin of every great discovery in medicine. We will mention, however, but two examples. When a student I used to wonder how it happened that Jenner, a country physician, gave us his immortal discovery. When I learned that he had been a favorite pupil of the great John Hunter, and had, for some years, resided in the teacher's house, the matter was plain. Who could have studied under this famous physician, surgeon and naturalist without becoming imbued with his zeal to do something for the benefit of the profession to which he belonged, and for humanity, which was his charge? I wondered also how it happened that the first ovariectomy should have been performed away out on the western frontier, remote from medical centers, in the wilds of Kentucky; how it could be that the great European schools had no part in it, and that New York and Philadelphia equally lagged

behind. But when I learned that McDowell had received his degree in Edinburgh, and had studied under old John Bell, who by his own personal force had built up under the adverse conditions of those times, a great school of anatomy and surgery, the mists cleared away. It became plain then how there arose on the border of an unknown wilderness the man with the requisite anatomic knowledge, the technical skill and, above all, the magnificent courage to do this operation, and, what was more, to defy the howling mob without, who threatened him with death in the event of a fatal result, while the sheriff waited to arrest him if he escaped from the mob. What finer example could be quoted of loyalty to the highest ideals, under the most trying circumstances?

All leaders of men, in all times, have benefited by the knowledge that high ideals were needed for great works. One of the best illustrations may be drawn from the history of our mother country. When Cromwell saw his irregular troops scatter before the king's cavalry at the battle of Edgemoor, he told Hampden "that decayed serving men and tapsters . . . could never encounter gentlemen and persons of quality." And did he then enlist men with broader shoulders or with thicker loins to fight the king's regular troops? No! He took advantage of the gloomy, religious fanaticism of that age, and gathered about him men who could lead a prayer meeting, or advance into battle singing psalms or storm a redoubt in the silent hours of night with equal ability. He led them to believe that in fighting the king's army they fought, not only for their country, but for their religion and their God; and these men, the Ironsides, became the finest body of troops the world knew, for they were never defeated in battle. Marston Moor and Naseby testify to the wisdom of their great organizer and leader.

But, you say, this was religion, and has no bearing upon our subject. But it has, for it makes no difference what the motive may be, so long as it is present. An equally striking example I can give from our own history. Ten years ago I examined a soldier for a pension, and drew from him this story: "He had been captured, after being wounded, with that battalion of Federal infantry which was sent into Cumberland Gap, to prevent the passage of hostile troops through that important thoroughfare. The Confederates, realizing its importance, had sent a heavy force into the gap from each end, and, after a hard day's fighting surrender became inevitable. The Federal troops were commanded by a major of the regular army, a West Pointer, who had grown up in the service, full of the etiquette and traditions of army life, and whose hair, as Scott tells us of Marmion's

* Was grizzled here and there,
But more from toll than age."

"As the Federal firing ceased a Confederate captain, accompanied by a cavalryman, dashed up and demanded the major's sword, the trooper meantime covering the major's breast with his carbine. Looking by the weapon's grim muzzle and observing the rank of his would-be captor, the Union officer said: 'Captain, I am a major in the regular army, and by the living God, sir, I will not surrender to my inferior in rank.' And the captain, marking the character of the man he had to deal with, replied: 'That's all right, major. I'll send for a proper person to receive your sword,' and he dispatched the trooper with

instructions to bring up the colonel of his regiment, to whom the sword was gracefully delivered."

And are we, the members of the medical profession, less susceptible to the influence of high ideals than this soldier who, his breast covered by a musket, the trigger pressed by a hostile cavalryman, faced death rather than yield one point in the etiquette of his profession? Are we less influenced by the traditions which come down to us concerning our proper mode of life than other men? Can anyone gainsay that the members of this society, or of our State society, do better work because they feel that they stand upon an equal footing with the best men in our profession in this State?

Did you ever study why it was that some physicians fail to attend the meetings of the medical societies? Perhaps it begins in carelessness or laziness, but sooner or later such men are likely to get so far behind their brethren that they do not attend because they are painfully conscious of the fact and fear to appear at a disadvantage. Such men remind me of a certain little boy who went to the great metropolis with his father. He was cautioned not to talk with the street arabs, because, being from the country, he would show his ignorance, and they would think him a fool. Finally, after asking him many questions without receiving any answer, one of his tormentors said: "Why, he must be a fool." And Freddy, bursting into tears, said to his father: "There, dad, I didn't say a word, but they found out I was a fool anyhow."

Further, the physician who does not associate with his fellows runs great risk of falling into one of two errors. Either he becomes an egotist because he fails to see the good work that others are doing, or, if of a timid nature, and faithful in his work, from knowing his own weaknesses so well, he feels that he is immeasurably behind his brothers in the profession. One can not see where he stands in the race unless he sees both those in front of him and those in the rear.

Let us, then, support warmly our medical societies. Let us inculcate into the minds of the younger men all that is best of the sacred inheritance which has come down to us from the earliest times, that they may know the debt they owe to the profession, and be led to attempt to add something to our store of knowledge, as an acknowledgement of the immensity of the debt. Let us instill into them ideals so high that they shall make of our occupation, not a mere trade, but what it should be, a liberal profession, and, I thank God, the noblest profession it is given to the sons of men to follow.

ORIGINAL ARTICLES.

MENSURATION OF THE DEFORMITY OF HIP DISEASE.

Presented at the Ninth Session of the American Orthopedic Association, Chicago, 1895.

BY A. B. JUDSON, M.D.

ORTHOPEDIC SURGEON TO THE OUT-PATIENT DEPARTMENT OF THE NEW YORK HOSPITAL,
NEW YORK.

The object of the present paper is to facilitate methods of recognizing, measuring and recording the degrees of deformity of hip disease. A great advance in the study of this subject was made in 1877 by our

Corresponding Member, Mr. Howard Marsh. I reproduce, in Figs. 1-5, the original figures with which he illustrated his first lecture on hip disease at the London Hospital for Sick Children. These figures, modified in various ways, have reappeared many times in the literature of this subject, and to one clinically familiar with these deformities they do not require explanation. Mr. Marsh's lecture contains a complete exposition of the mechanics of the deformity of hip disease, and it will not be easy to add anything to what he has said.¹ I have, however, constructed the movable models represented in Figs. 6-10, in order to make this difficult subject more easy of comprehension.

FIGURE 1.

FIGURE 2.

As seasoned practitioners we appreciate at a glance the clinical significance of abduction or adduction when combined with fixation. Abduction means apparent lengthening and adduction, apparent shortening. Abduction and lengthening, adduction and shortening, flexion and lordosis, are to us mentally interchangeable terms, but it may not have occurred to us all that these factors of deformity may be easily measured and recorded, and that we may thus better appreciate the importance of affording relief and the merits of whatever method we may adopt to remove or prevent deformity. The dolls, in Figs. 6 and 7, were arranged and photographed several years ago. They show graphically the degrees of motion and deformity, but they can not, from the immobility of

FIGURE 3.

FIGURE 4.

FIGURE 5.

their vertebral joints, show the effect of the disease on the length of the limb or the curve of the spine. These effects are, however, shown in Figs. 8-10, in which figures cut out of press-board take the place of dolls, and are so put together that they exhibit motion, and also the arrest of motion, not only at the hip, but also at the vertebral joints.

The figures explain themselves to a certain extent. The joints are made of eyelets not pressed too hard with the "eyelet-set," and loosely screwed to the background at V in the full figure, and at H in the profile. The piece representing the thorax in the profile is reinforced at the back by a thin piece of brass, as

the edges of the press-board were found to wear out against the four screws which act as guides. The spring clip is a "scarf-retainer." The apparatus is easily made, and is useful in class demonstration.

To show the effect of lateral deviation with fixation.—The full figure is first arranged symmetrically as in Fig. 8. The clip applied at A binds together the piece representing the pelvis and that representing the trunk, and thus prevents motion in the vertebral

FIGURE 6.

joints, at V, while motion at the hip joint is free. The limb is then drawn into adduction, as in Fig. 9, and the clip is removed from A, releasing the vertebral joints, and applied at B, where it fixes the hip joint, at H, by binding together the pieces representing the pelvis and the femur. When an attempt is then made to restore symmetry or to make the limbs pa-

FIGURE 7.

rallel, the figure exhibits tilting of the pelvis and apparent shortening, as in Fig. 10. In like manner, abduction and fixation may be made to produce apparent lengthening. A fortunate result is that in which the patient recovers with enough apparent lengthening to annul the real shortening caused by loss of bone or unequal growth.

To show the effect of flexion with fixation.—The cuts may be turned sideways so as to present the profile recumbent. The clip applied at A, as in Fig. 8, binds

¹ British Medical Journal, July, 14, 1877, pp. 37-39.

together the pieces representing the pelvis and the trunk, and thus prevents motion in the vertebral joints, V V, while motion at the hip, at H, is free. The limb is then raised in flexion, as in Fig. 9, and the clip is moved from A to B, releasing the vertebral joints, and fixing the hip joint. When an attempt is then made to reduce flexion or lower the limb to the table, the result is lordosis, as in Fig. 10.

It is interesting to note, by observing the transverse dotted lines, that the patient's height is in-

FIGURE 8.

creased by either adduction or abduction, and decreased by flexion when either is combined with fixation. The height is diminished in lateral curvature of the spine by the sigmoid curve, in Pott's disease by kyphosis, and in hip disease by lordosis. The deformity of hip disease may readily and with sufficient accuracy be measured by the use of the goniometer, two forms of which are shown in Figs. 6 and 9. This instrument is simple in construction and may well be in frequent clinical use. The one shown in Fig. 9 is made by attaching arms to a protractor.

FIGURE 9.

To measure adduction or abduction.—The limb is slowly moved in the direction of adduction and abduction alternately until, after repeated trials, it is seen that when it is held at a certain point in the arc of lateral motion the iliac spines are at right angles with the axis of the trunk. One arm of the goniometer is then held parallel with a line connecting the iliac spines. If the table is against the wall of the room, it is convenient to see that the iliac spines are at right angles with the wall, and then the arm of

the goniometer may be directed point blank at the wall. The other arm is then made to coincide with a line parallel, as near as may be, with the axis of the limb, which may, for this purpose, be considered to extend from the middle of Poupart's ligament to the middle of the heel. If the axis of the thigh only is considered, the incidental presence of genu valgum or varum would impair the value of the observation. The degrees may then be counted on the scale of the protractor.

To measure flexion.—With one hand the limb is slowly raised and lowered until, after repeated trials, it is found that, when the limb is held at a certain point, the lumbar spines press gently on the fingers of the other hand placed under the back. One arm of the goniometer is then held horizontally by the hand released from under the back while the other arm is made to coincide, as near as may be, with a line parallel with the axis of the mass of the limb. The degrees then read off on the inner scale of the protractor are degrees of flexion. Although its determinations are, from the nature of the case, only

FIGURE 10.

approximate, the goniometer is an instrument of precision, and easily makes itself useful in practice.

Writers on this subject have usually viewed deformity as the result of immobilization of the hip joint. The figures and models referred to in this article have been constructed with that view. As a matter of fact, however, few cases present absolutely immovable joints at any stage. There is almost always considerable motion. In the acute stage the joint, which at the first glance appears to be motionless, is found to yield through an arc of many degrees in response to gentle force rightly applied. Later in the course of the disease many cases show wide and free passive motion in different directions, and the point at which motion is arrested often varies from day to day. And even in after life the position of the limb is subject to considerable variation. The use of the goniometer facilitates recognition of these phenomena. Further observation in this direction may add to our knowledge and to the efficiency of treatment.

Artificial Larynx. At a recent meeting of a medical association in Berlin, Glück presented two patients with artificial larynx he had treated during the year. One, a middle-aged man, could speak naturally and distinctly although the entire larynx had been removed. *Therapeutische Wochenschrift*, January 18.

NORMAL MIND.

BY J. SANDERSON CHRISTISON, M.D.

INSTRUCTOR IN NEUROLOGY, COLLEGE OF PHYSICIANS AND SURGEONS
CHICAGO; ATTENDING NEUROLOGIST TO THE WEST SIDE FREE
DISPENSARY; FORMERLY OF THE NEW YORK CITY
ASYLUMS FOR THE INSANE, ETC., ETC.
CHICAGO.

PREFACE.

The scope of this article is little more than a suggestive outline of the subject in a fragmentary form. While some of my positions may be regarded as neither proven or self-evident, I am persuaded their correctness will become manifest on a careful consideration. At a later date I expect to deal more fully with some of the points under other headings. I have treated the question by contrast which will give a more accurate view than could otherwise result.

DEFINITION.

By the term normal mind I mean the prompt and coördinate action of all the mental faculties coexisting with pacific disposition or temper. It has no reference to knowledge in the numerical sense, nor capacity in the geometrical sense, but simply that state of mind which enables the individual to do his best in any given relation.

GENERAL ASPECT.

Of ten business or professional men selected at random, at least eight would commonly be regarded as normal in the sense of being representative of the community standard of free agency. But these eight will differ one from another to such an extent that each may meet his opposite in views and disposition in one way or another, and yet the faculties of perception, reason and will may be regarded in all as in good working order. Between the common types of different races and nations the same condition exists, a condition which, barring the difference of language, precludes harmonious action on any question of common interest, without a wasteful expenditure of both time and energy. This is evidence that the common normal is not the complete, and that perception, reason and will are somehow defective. But as there is naturally no essential difference between man and man viewed from both psychologic and physiologic standpoints, this difference must be due to difference in ideas and habits, and as every act not naturally instinctive is originally the product of an idea, the question of cause is resolved into: What ideas conduce to the really normal mind or approximately perfect?

When we consider the nature of ideas, it is evident they are not only true or false, but vary in importance or value as measured by their utility as means to an end—the scope of their application to final purpose, whatever that may be. Ideas of purpose being both the product of elaboration and motive to acts are either conservative of energy, or have an opposite effect, directly or indirectly. But as tone of brain is the equivalent of tone of mind, owing to mutual dependence, it is evident that a false purpose will induce a dissipation of energy which will reduce the intellectual range by its enfeebling effect. Thus the question arises, what ideas of final purpose are in harmony with nature that we may live to the best advantage—be serene in mind—coördinate with natural or necessary environment. To this end we might take the characters of great men who have been universally loved and respected, and find their actuating principles, which have done far more for our well-being than have pills and powders. We would find, on

careful analysis, that the dispositions of egotism, malice and fear were seldom, if ever, manifested as they rarely existed.

EVOLUTION OF CHARACTER.

When we consider mind as an entity, the question of its environment begins at the germinal stage of life—the relationship of the chromatic (Weismann) elements to the differentiating entity of the protoplasmic nidus or environment, and which entity is finally manifested as mind. Excluding maternal accidents, the formative forces prevail under prenatal laws with the minima of impediments. At birth, the new environment with its stimuli to the senses, gives mental motions to a potential basis which is gradually cradled, so to speak, into manifest consciousness. The cosmic conditions, as ever present factors in the molding of the infant mind, pave the way for the apprehension of those great and everlasting impressions or intuitions which later dawn upon the reason and stir the powers to still greater action. Thus that eternal monitor, the conscience, is evolved alike in all human beings. Though as unalterable as the fixed laws of nature, of which it is the exclusive product, conscience may be perverted or clouded by criminal career or criminal influence—crimes against truth, justice and economy. For the same reason that conscience is a fixed quality—the product of the fixed laws or operations of nature, and therefore of necessary experience—the inherent disposition against all aberrant conditions, physical and mental, is to assume the normal, a result that will always ensue if the evils of inherited bent and environment are not too strong for the healthy remnant. Otherwise “the weakest must go the wall,”—the wall of dissolution.

The infant mind is *passive*, receiving every impression with positive effect, and as the evil habits and conditions which contributed to its protoplasmic impress, or hereditary defect, may still rule the nursery, it is evident that mental restriction must follow with conscience crowded out of notice, or pointing in vain. Heredity, as the cumulative effect of all experiences cosmic, racial and ancestral, must necessarily give the child a bearing toward its external environment (trans-somatic) which will vary with the differences of transmitted impress, and consequently inclination and intuition will have different bents. Indeed, so powerful is transmitted bent that not uncommonly a child of criminal ancestry, though systematically educated under good influences, will revert to the criminal class, just as sometimes the young Indian from college does to his racial habits. Of course, the civilizing influences have only been *conforming* in effect, *not reforming*. Such disposition is due to the irksomeness of inaptness, a sort of intuitive leaning having a potential basis. Thus by early training, the natural, the necessary intuitions of the mind may be displaced by purely selfish ideas and criminal character be formed, such as the character of the burglar or the political or commercial knave. It is such cases that must be “born anew”—radically changed in views—before they can be brought in harmony with natural economy—with the great final purpose of nature which can only be correctly apprehended, even in part, by the normal mind—the fully free.

The stage of infancy is ruled by instinct and intuition almost entirely in the acquisitive form. At first ideas associated by suggestion gradually dispose the mind to analysis, then synthesis, and the faculties of

recollection, judgment and reason slowly evolved in due order. The experiences of all children, naturally treated, are essentially the same, so that when they arrive at the age of reason, instinct and intuition lose their official importance and questions of conservative interest arise for rational consideration. Later on the question of final purpose dawns upon the youthful mind, and though it can not be logically solved by it, experiences and intuitions have given sufficient assurance that certain things are right until intelligence makes duty and purpose more definite and distinct. Here, I may observe that the child of the country—of pastoral surroundings—being freer from artificial distraction than the child of a metrop-

olis, is more profoundly imbued with the results of cosmic impressions, and thus later in life is more likely to acquire prophetic insight. Thus the untutored mind of the peasant, as illustrated in the "Cotter's Saturday Night," may evince great wisdom and peace because of living in line with a final purpose in harmony with intuition and *common-sense*.

STATES OF MIND.

Self-possession is the essential characteristic of the normal mind. It is the condition of the greatest freedom of the will and power of attention with which it is commensurate. The power of discernment and the power of choice are at their highest degrees, and are at all times ruled by fundamental prin-

SKELETON No. 1.

SYNOPTIC ANALYSIS OF THE COGNITIVE FACULTIES.

(In the order of their evolution.)

ACQUISITIVE.
(Perception.)*Internal Perception.*

Consciousness of Self through contrast with externals in translation—Perception proper.

External Perception.

Consciousness of externals through their effect on the senses—Sensation.

CONSERVATIVE.

(Memory.)

Sub-conscious ideational coherence by the law of Association operating in inverse ratio to the time, space and causal distance between things (ideas). It is the "heart" or storehouse of the intellect.

REPRESENTATIVE.

(Imagination.)

Suggestion.

The involuntary return of ideas to consciousness through natural or association affinity. (Common to all animals).

Recollection.

The voluntary reproduction of ideas to consciousness according to individual habit or system. (Exclusively human.)

ELABORATIVE.

(Relational.)

Analysis.

Separation by affinities or qualities or structural relation.

Synthesis.

Conjoining by affinities or qualities or structural relation.

Judgment.

Affirming a similarity or dissimilarity between two things.

Reason.

The comparison of two things with each other through a third.

Intuition.

The sub-conscious action of the mind in a new and conscious relation bearing a concept.

Instinct.

The inherent faculty of lower and undeveloped organizations operating in lieu of reason or experience for conservative ends.

REGULATIVE.

(Reason and Will.)

Common sense—*a priori* or First Principles—the product of necessary or common experience—in action with new relations.

NOTES.—(1) A mental faculty is an inter-dependent mode of activity.

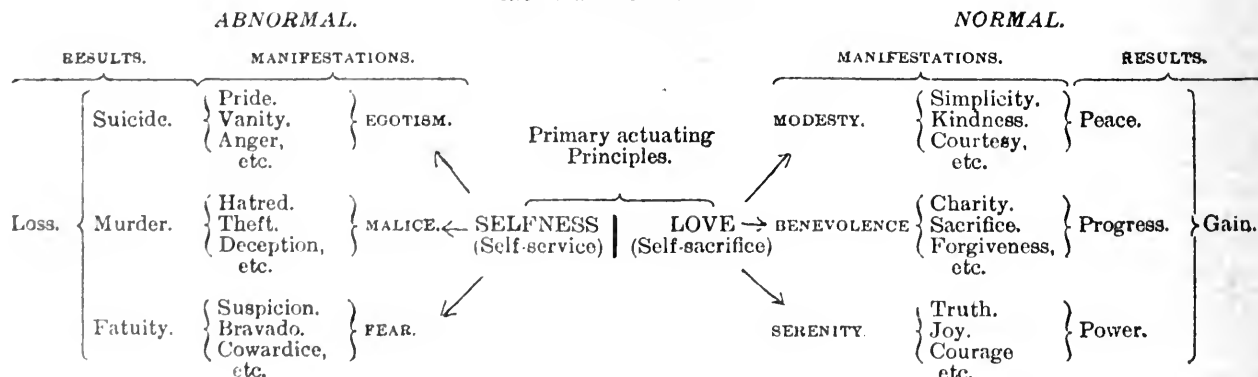

(2) *Active* Attention or the power of voluntary direction and exclusion is a measure of the freedom or power of the Will; the Will is dependent on Reason and Reason on the efficiency of the subsidiary faculties.

(3) The mind being ever active is always in a new relation.

(4) Instinct is the first manifestation of mind, Intuition the later and Reason the last or highest.

SKELETON No. 2.

MORAL DISPOSITIONS.

NOTES.—(1) Few, if any, individuals are exclusively the one or the other, but usually vacillate between the two principles owing to weakness. The one may wear the appearance of the other and thus have failure or success accordingly, viewed from the standpoint of fundamental principles.

(2) By *suicide* I mean either a violent or slow process of self-destruction. By *murder* I mean either a violent or slow process of destruction to others. By *fatuity* I mean that state of mind which has such a mixture of both these dispositions that more stupor than impulse results.

THE PHILOSOPHY OF DEGENERATION.

OR CAUSATIONAL ANALYSIS OF MIND FAULT.

Premise.—The power of Discernment with the power of Choice implies commensurate personal responsibility, therefore degradation has primarily a *moral* cause and finally a *mental* result, or reduced capacity for enjoyment.

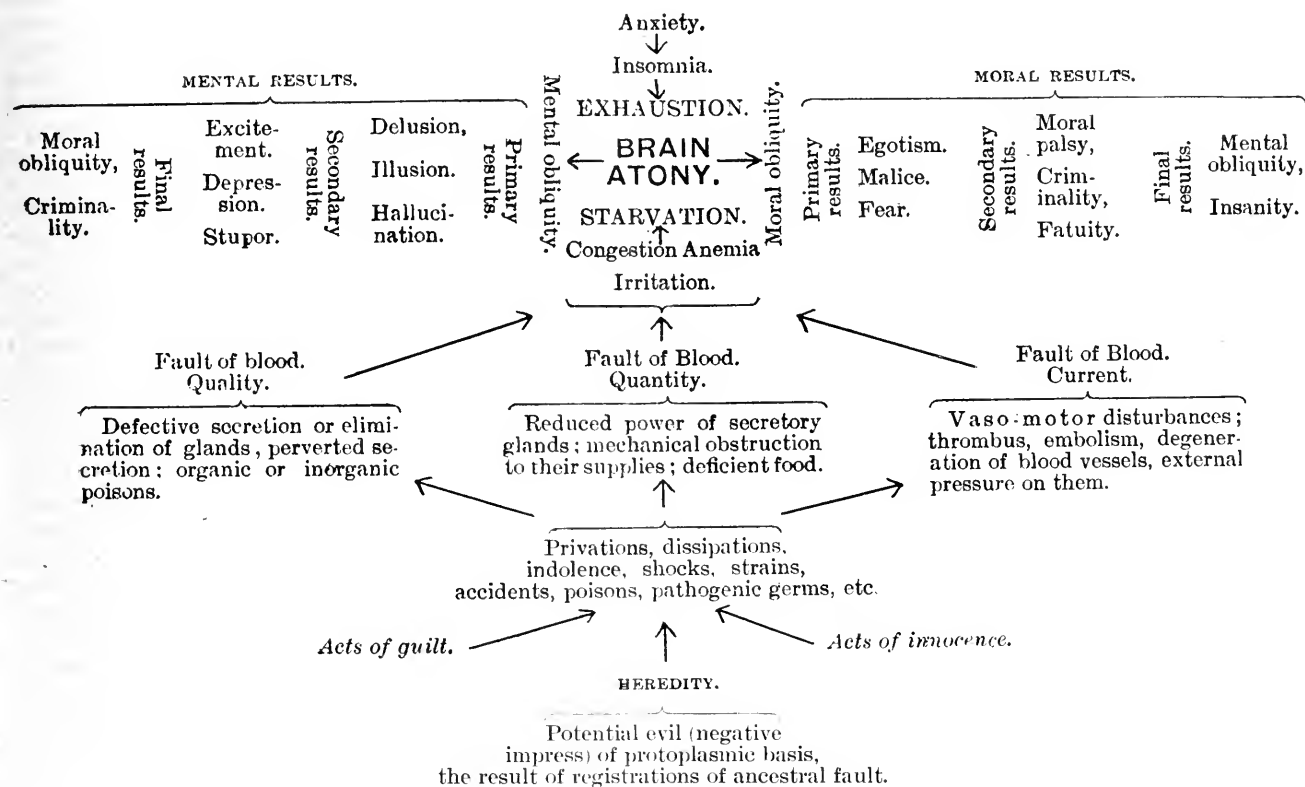

MENTAL ASPECT.

Moral Fault.

Def.—Any condition against our best welfare or final purpose.

Acts of guilt.
Shame,
Remorse, Despair, etc.
Fear.

Acts of innocence.
Defeat,
Loss, Injustice, etc.
Grief.

PHYSICAL ASPECT.

[Result of moral fault.]

- NOTES.—(1) Brain atony is any condition of brain which does not balance with the normal or fixed forces of nature and is relative to individual capacity.
(2) Causes and effects operate in a circle and run parallel to each other.
(3) Insomnia is deficiency of brain *rest* in any degree.

ciples. Full self-possession contains no egotism, malice, or fear, for it is the necessary product of logical living. The great and self-evident fact that the highest good to self is dependent on the attainment of the same by others is an ever-ruling principle of it, with the sense of duty from the dictates of conscience. One of the first great impressions which naturally comes to the human mind is the sense of absolute dependence—the law of gravitation, so to speak, in the psychologic world. Following this, the fact of inherited environment with its many and varied misfortunes, whether of wealth or poverty, gives basis to charity, which when logically exercised, works for harmony and efficiency along all progressive lines. Thus we gather guiding principles which with growing knowledge lead to a fuller recognition of our relationship to time, eternity and an infinite personality, and while we perceive our

high dignity in natural economy, we carry the conviction of self-insignificance. Witness the modesty, the magnanimity and the self-sacrifice of true greatness.

But these great and guiding principles which work for harmony and evolution may be stifled in their birth by the inculcation of morbid or false teaching and example, and thus the selfish character develop with egotism, malice and fear as necessary conditions.

A typical case of undiluted selfish character came under my notice in the New York city workhouse. He was a man about 30 years of age, and by occupation a burglar. He had served several times in the penitentiary, but was committed to the workhouse for one year on a minor offense. As prisoners were allowed more liberty during their last month's service, I engaged him to shave me in my room that I might have the opportunity of finding the roots of his

character. He was an unusually nice looking, shapely and clever fellow, facts that seemed incompatible with his history of early and continued crime. After discussing all sorts of questions with him at different times, the fact was revealed that he firmly held the belief there was no future state, and that it was reasonable to get everything *now*, no matter about the rights of others who possessed whatever he wanted. Thus all his niceness was policy.

Egotism as the "I am" what I am actually not, is quite a different thing from the positiveness of decision, the assertion of a truth, or heroic action. It is an exhibition of personal importance with disrespect for others without just cause, and arises from a selfish disposition to be esteemed more than our merit, with a delusional basis. It is very common and conspicuous among the insane and is essentially an abnormal product.

Malice, as the disposition to injure others purely for the sake of inflicting pain or antagonism, or in some cowardly indirect method of "getting even," is quite a different thing from punishment for a wrong, which, though it may be ineffectual, is curative in its tendency. It springs directly from selfishness as an attitude for its own protection along its selected lines, and with no disposition to apologetic considerations.

Fear is the product of uncertainty—a necessary condition of selfishness and comes from the obscurity which necessarily more or less exists in all abnormal states of mind and acts therefrom, whether of guilt or disease. To live in the light of fundamental principles (common sense) is to have such a telescopic view of life that consistent action can bring no fears. Not to so live is to live in shade or obscurity, so that acts must carry with them more or less uncertainty of result and fears arise. The innocent in view of the final result in the light of final purpose can have no fears. The fear of childhood is the fear of imperfect understanding and is as transient as the cause. Fear from guilty acts is the fear of conscious desert of punishment and has reference to unknown remote results with indefinite persistence.

Grief as the effect of unavoidable or unintentional evils has a disturbing action on the mind because of the element of uncertainty of result or personal responsibility and is therefore a form or degree of anxiety. It is frequently associated with personal misgivings of our own real or fancied delinquency in relation to the object and is thereby mingled with fear of a harsher nature akin to that of guilt.

Anger like fear works to the disadvantage of the subject and consequently is not a normal state of mind. It is precluded by a clear and full view of the whole situation and its relations, with complete self-possession—conditions depending on a full acting brain. Anger is a *product* of all abnormal dispositions of mind and brain, though not always manifested and while in its nature it is a symptom of imperfection it is the least aberrant of all abnormal dispositions of the mind. It is simply a disturbance of temper or co-ordinate mental action. Complete immunity for it would imply absolute perfection—a somatic impossibility.

Love is the outflow of the sense or realization of mutual dependence, mutual need of reciprocity. It is therefore the normal product of instinct, intuition and reason and thus it may have many forms according to whether instinct, intuition or reason predominate in serving the cause. Love begotten of intuition

is the most intense, that of reason is the most lasting. It is the assurance of harmony and coördination with nature and is the root of all conservation of energy in the line of true advance. It is the sacrifice of present personal gratifications which are in conflict with evolutionary ends.

Sociability.—Man normally has a social disposition which in childhood is general or promiscuous just as talents carry with them a desire for their use. As years increase this disposition becomes more and more select for specific purpose of mutual advantage and for that purpose systematic exclusiveness is required for the attainment of a particular end, otherwise there would be dissipation of energy. Thus while sociability is normally a product of love it can be claimed only by the fitness of means to an end and therefore an exclusiveness may result manifested as an eccentricity. Difference in habits from the conventional (eccentricity) due to exclusiveness for a rational purpose indicates intensity of character above the common, but otherwise eccentricity is a symptom of degeneration.

BRAIN RELATION.

The theory has been advanced that mind is a function of brain in the same sense that bile is a function of liver.

1. Were this a fact a portion of brain would represent a quantum of mind just as a portion of gland is a measure of its secretory product, which is not the case, for almost the whole of either hemisphere of the brain may be destroyed and yet the mind remain intact though it loses in its power of endurance for work. This fact demonstrates that mind is *supra*-material and is in no sense the elaboration of brain, but is only *conditioned* by a *product* of its cellular action—a product akin to electric energy, and which makes motor and sensory action possible. This cellular product bears much the same relationship to the nervous system as does electricity to the telegraph. The possibilities of the mind are therefore conditioned by everything that contributes directly or indirectly to the supply of brain energy and the integrity of its specialized centers which are probably as numerous as are the specialized organs of the body or their functional requirements.

2. The fact that the size of the brain and the number of the cortical cells are almost completed in the child, which is not true of any permanent gland, is also a fact against the analogy.

3. That the function of brain, aside from its being the location of communicating centers, is simply the production of an energy subservient to mental activity and organic life is strongly supported by such facts as that the brain of the *monk* monkey is much simpler in its convolutional form than many of the larger quadrumanas of inferior intelligence and it is even much simpler than that of so stupid a creature as the sheep. The cerebral convolutions of some monkeys as the *howler* are about as few and simple as a frog's. The clever beaver has a cerebrum devoid of any convolutions whatever, while our congener the hog which seldom has more than one and the same idea in life, is well supplied with convolutions. Thus the evidence is that while convolutional complexity is a matter of economy of space for increasing energy it is not necessarily in proportion to intrinsic intellectual eminence and that mass, proportion and complexity of brain convolutions are a measure of the

power of endurance, of energy production, rather than intellectual eminence.

4. The fact that histologic elements of the cerebral cortex of all vertebrates are much the same and also much the same in all parts of the cortex, is in favor of the energy theory.

5. The fact that excepting (possibly) alcoholic and traumatic insanities, the pathology and morbid anatomy of almost all forms of mental aberration are essentially the same.

6. Lastly but not least of importance as bearing on brain function, is the fact that mind has unlimited growth which no secretion of a gland has not even the energy produced by brain.

There is no such condition as disease of the mind pure and simple, for all mental fault and ideational error imply an abnormal state of the brain inherited or acquired, otherwise *perpetual* chaos would result. For the same reason that matter is indestructible, mind is immortal, and for the reason that precisely the same result can only take place when all the conditions are precisely the same as before, character can not be changed post-mortem, in any way possible ante-mortem.

THE FACULTIES.

By perception, reason and will we commonly include all of mental action. The one can not exist without the other, but they embrace distinctive modes of mental process, as seen in the accompanying analytic table.

The *acquisitive faculty* is the power the mind has of receiving impressions through the peripheral system and translating them into ideas. So keen can this power become that disciplined observers can accurately note hundreds of objects in a room by a glance on passing its door and afterward describe every detail which was within view. In my own experience in early student days, I acquired the faculty of reading a whole line at a glance, or about as quickly as I now ordinarily do a word. That the mind is also constantly receiving impressions which are not consciously perceived at the time is evidenced by somnambulistic feats and the doings of persons pre-occupied. The case of an ordinary female servant who in the delirium of fever repeated whole passages of Greek and Hebrew which had been recited within her hearing years before, and which she neither understood nor gave attention to at the time of hearing them, goes to show that nothing can impinge upon the senses without becoming a mental acquisition, though impressions at the time may pass unrecognized.

The *conservative faculty*, or the power of holding impressions or ideas subconsciously for future use, preserves all experiences and thoughts, classified according to one relationship or another, and therefore made more or less available for use when needed.

The *representative faculty* is commonly known as memory, but is properly the power of the mind to reproduce ideas from memory. It is either voluntary or involuntary, but in man usually both, and in the purely voluntary form is exclusively a human faculty. Voluntary reproduction, strictly speaking, is a process of exclusion in favor of certain lines of association. This faculty habitually exercised can perform wonders compared to the degree in which it commonly exists. Indeed, some persons can instantly recall almost any forgotten experiences. When a lad

of 16 years at Edinburgh wading through the ponderous tomes of Turner and Liebig's chemistry, I systematically tested my recollection after four or five hours' consecutive study, covering forty to fifty pages of new matter, and found that at times I could not only recall many of the ideas but also the page and setting containing them in pictorial representation. This faculty improved by practicing the careful re-tracing of thoughts by sequence. The faculties of perception and recollection show what a mass of mental material exists subconsciously, only to be brought in view when the mind is fully emancipated from somatic conditions. Later on when a student in London, I practiced as an experiment for a number of weeks the habit of daily reviewing my experiences in minute detail, beginning with the last sensation or thought. Between 5 and 6 p.m. I would comfortably recline upon a sofa and close my eyes. At first the task required considerable effort to connect all the perceptions of a day, but I soon acquired the power of reviewing the experiences (subconscious perceptions) of many months within a space of time less than an hour. I found that by *directing* my attention to a given point and then holding it *passively*, ideas would instantly cluster about the central one by the natural law of association—suggestion. I would have a pictorial representation in natural order and seemed to again experience something of the original feelings that accompanied them. The review seemed complete, although some fields of experience required more effort than others to complete them. But the most remarkable revelation was the rapidity with which I sometimes could cover a large territory—many thousands of perceptions—within a few moments. It was mostly by *suggestion* and only partly by *recollection*.

The faculty of *Recollection*, depending as it does upon a conventional system or predetermined line of association of ideas by the individual, is one of the latest evolved and highest faculties of the intellect, so that when degenerative changes of the brain take place, it is one of the first to weaken. For example, a person may be able to speak and write numerals to some extent, because they represent the simplest kind of natural relationship—an evolutionary order or systematic proportion of one quality—while the same person may forget the alphabet, which is an *artificial association of different qualities*.

The *Elaborative faculty* is the power of the mind to relate things according to purpose or plan. Its highest form is *Reason*, which calls in service every mental process. Reason is largely dependent on the faculty of recollection—the faculty of recalling anything *wished* through a system preëstablished by the individual. This enables reason to advance beyond intuition and also produce certainty for surmise. Reason pure and simple is the last and most complex faculty evolved, and as the creature of self-discipline it is the first faculty to weaken in most brain degenerations. This is why fixed delusions usually appear long before the simpler faculties show any marked enfeeblement. I doubt if reason, strictly speaking, is possessed by any other creature than man.

The *regulative faculty* is the presidential power of the intellect, but with no more power of action than is delegated by its constituents, the subsidiary faculties. Its strength of action (the will) depends upon the relative efficiency of all the mental faculties governed by fundamental or first principles discerned

by intuition and reason from necessary or universal experiences and known as *common sense* (not common notions). They are the principles that work for harmony and evolution.

Instinct is the expression of elaborative efforts of organization and parts for conservative ends. There are three principal forms: 1. Cosmical instinct, or the instinct of *first acts*, such as the sucking of the babe, or the pecking of chicks—for the *preservation of the individual*. 2. The instinct of *sexual attraction*—for the *preservation of the species*. 3. The instinct of *preponderating talent* or the desire to exercise an inherited power—to the *advantage of the species* for final purpose (evolutionary end). As a propensity, instinct is the first manifestation of subconscious elaborative action, which is a necessary condition of growth and experience.

Intuition is also a subconscious action of the mind, but bearing a *concept* as a product, instead of a *propensity*. It is a faculty common to all the higher animals and is often mistaken for reason in them. It is the power of the natural or poetic mind as distinguished from the *logical*. If the state of the mind is normal and the related subconscious data are correct, intuition must be accurate when pronounced. Such a condition is only approximately attainable. But our great motive ideas are mostly intuitional, more or less, as few minds can consciously calculate to a conclusion with all the data involved even in everyday problems. Women, who commonly live more *naturally* than men, possess it in a higher degree, and in those who are well informed and conditioned it is more reliable than the exercise of reason in the imperfect form so common.

Attention.—The power of attention is the power of the will and is the first condition required for the appreciation of an object by the perceptive faculties. If it equals the measure of scrutiny and if the measure of scrutiny equals the nature and number of ideas engaged and the order in which we bring them to bear on the object, together with the manner in which the object is exhibited then the impression or notion received of the object will accord with the measure of attention given it. In mental fault the attention is weakened and the subject is more or less passive, as in infancy, so that perception is incomplete. Attention is given more to the *pro* side than the *con* side of the thing presented or the quality suggested and if the favoring circumstances remain undiminished, complete subjection (hypnotism) will result. Arrest of attention is palsy of the will which is subjectivity of the mind.

Emotion is a normal condition, but in its manifestation is inversely proportional to intellectual range. It is the product of suggestion on subconscious factors in the mind in accord with the law of the association of ideas. In normal mind it can be controlled by the power of the will to exclude or substitute ideas as directed. Emotion is most profound in the intellectual but least manifest as there is less physiologic excitement, because of greater self-possession which is equivalent to a higher tone of the nervous system. It is most manifest in those who have a *poetic* habit of mind rather than a *scientific*—systematic or logical, and thus they are more or less subjective to external direction. The subjective state of mind is equivalent to passive attention or the taking cognizance of nothing but evidence of support and thus hypnotism or mesmerism may be induced by an exclusive direction

of attention instituted by a second person. Voluntary exclusive direction of attention to a *negative* object will induce auto-hypnotism. Ordinary manifested emotion is largely an expression of confusion and weakness. No one can be hypnotized without assisting and many can not resist. It is this rendering an audience subjective, or gaining passive attention by *direction* or control that is the secret of the orator's success. Emotion (feeling) is largely the product of the actual state of the bodily organs which are more or less influenced by thought. Pain or misery, like hunger, is the expression of a need, and the feeling of well-being is the expression of satisfied claims for physiologic requirements. Perversions of different organs have different effects or suggestions on the mind by their sensory influence. The different mental effects of drugs is thus probably due to their action on one or other of the various vegetative organs by the selective affinities of their different cell elements which each possesses, rather than on any direct action on the brain.

NORMAL DECADENCE.

Dotage or second childhood is commonly regarded as the normal terminal of old age. But as over all other organs the brain is much the least affected by general waste or starvation, it would appear that the mind should retain its powers much beyond those of the bodily frame. As a step toward the solution of the question as to the normal disposition of the mind in advanced age to recur to early experiences I communicated with a number of distinguished persons advanced in years in regard to their personal experiences, and who have most kindly replied to my inquiry. I here present the experiences of two men and two women who, at the date of writing me, were in good health and actively engaged in one way or another.

From Mrs. Elizabeth Cady Stanton, now over 80 years of age, and at present preparing her reminiscences, I glean the fact that her mind is strong and active with a vivid memory. She says: "I love to think over the joys and sorrows of my childhood and girlhood, and to see myself in pictures as I looked then." She thinks "there is an immense advantage in doing this as it makes us more sympathetic with the young, more tender with their trials, and more desirous to make them happy. I would feign save childhood from suffering what I did from restrictions." But her opinion is that "with a vivid, keen memory, all persons must more or less dwell in the past. Those who retain an active interest in the questions and reforms of their day, would, on the other hand, be more occupied with the living present."

Miss Francis Willard, 56 years of age, President of the National W. C. T. U., says: "I have observed for some time past that I was growing inclined to think of that which had been of especial interest to me in my childhood and youth. The same tendency was clearly manifested in my dear mother who was with me until the 88th year of her age, and who retained every faculty until the end. So far as my observation goes, this tendency is strongly marked in all people who are known to me. The more years, the more backward looking over, though they may be profoundly interested in and preoccupied by current affairs."

The Hon. Joseph Medill, editor Chicago Tribune and President of the Chicago Press Club, 73 years of age, says: "I can discover no further change in the

action of my mind than can be accounted for by experience, further study on many topics, and wider observation of men and things. The most marked change is that memory of the more recent occurrences seems weaker, less accurate, especially in dates, names and sequences of events. My mind recurs to youthful events and dwells on pleasurable or painful matters which then took place, the memory being quite vivid and accurate of things which happened in my teens or the first decade thereafter. I believe this is the experience of most elderly persons. My judgment or reasoning powers do not seem to be impaired with advancing years, though I can not think or conclude as rapidly as in past years, but consume more time in arriving at fixed conclusions."

Ex-Governor Oglesby, thrice governor of Illinois, now 72 years of age, writes me: "I can not say that my mind recurs more frequently to early experiences in advancing age than it did formerly in younger years. As a matter of fact, I have always delighted in reflection upon and remembrances of my childhood days. I suppose this is quite common with all rational beings."

It is thus evident that the normal dispositions of the mind in advanced age are retrospective and contemplative. Early experiences are the more profound and enduring in their influences on life as "the child is father to the man" and they sink to obscurity by the calls of an ever changing environment of necessity and ambition, until, finally, the pinnacle of experience is reached and historic contemplation begins. The acquisitive faculty wanes with the decline of the sensory and motor powers, and things of recent date become less impressive. Thus, the disposition to retrospection is born of the growing retirement from the daily cares of active combat and the punctuation points of early life which lie at the basis of all character, press forward for the consideration of the wisdom that comes with maturity of decadence as a blessing to rising generations. But the process of degeneration as differing from normal decadence must play a part, though ever so slight, for it is not to be presumed that heredity and environment will leave any individual untainted with the effects of their evils. Also, the highest type of the individual through strain of ambition, may forget the inexorable exactions of nature and thus trespass the conservative limits.

It thus would seem that dotage is not a normal or necessary condition of old age, but a product of degeneration as differing from normal or necessary decline, when at last the servile mechanism of the mind fails to furnish the degree of energy requisite for coöperative labor, time and space cease to be factors in the evolution of the individual and the veil of mystery—the occasion of all effort—remains as ever, to solicit the attention of the living and spur the strong to thought and conquest.

SUMMARY—THREE PRINCIPAL POINTS.

1. That mind is a distinct entity in which there is no heredity, otherwise endless chaos would result. Heredity is exclusively protoplasmic.

2. That for the same reason there can be no *disease* of mind pure and simple, but that wrong ideas in action necessarily induce disease of the brain, and as one evil begets another, disease of the brain begets wrong ideas, which may become fixed against reason—insanely delusional.

3. That the normal state of mind is self-possession and peace, which is the result of self-sacrifice for a satisfying final purpose.

103 State Street.

THE TREATMENT OF NASAL CATARRH IN THE LONDON CENTRAL THROAT, NOSE AND EAR HOSPITAL.

BY FAYETTE CLAY EWING, M.D.

Late Senior Clinical Assistant Central Throat, Nose and Ear Hospital and at the London Throat Hospital; Fellow of the British Rhinological, Laryngological and Otological Association, and of the American Medical Association.

ST. LOUIS, MO.

It occurred to the writer that the treatment of the several forms of nasal catarrh pursued in the Central Hospital would prove interesting to many of the readers of the JOURNAL.¹ Five varieties are recognized, viz: Acute, chronic, hypertrophic, chronic atrophic, croupous and caseous. The first of these presents few cases in hospital practice, and the last two are so rare as to be regarded as clinical curiosities.

Acute.—Since patients with this form of rhinitis rarely consult a physician until the acute stage has passed, little is attempted except prophylaxis. This includes abundant open air, exercise under restrictions, and hygienic dress. Light wool next the skin and variable weights of over-garments. Heavy garments indoors are specially cautioned against. No agent is more relied upon for its hardening effect than the morning sponge bath with cold water. This should be taken in a warm room, and supplemented by vigorous rubbing with several towels, the last of which should be a coarse crash. When these rules are observed the most delicate person will suffer no ill effects from the bath. Among drugs the first place is given menthol as a prophylactic, and also a modifying agent when the affection is once set up. Cushman's menthol inhaler is recommended to be carried in the pocket, and used frequently during the day as a hardener of the mucous membrane. Menthol is germicidal, and stimulates the capillaries to contraction, thereby relieving obstruction. Cocain, though accomplishing this result much more rapidly, is never prescribed for the purpose, since it produces, after a few applications, dilatation of the vessels, setting up the trouble it originally palliated, and further, there is always danger of the cocain habit being established. During the second stage a mixture composed of camphor, opium and belladonna, in stimulating doses, is advised to be taken between meals.

R. Tr. opii aa gtt. v. 30
Tr. belladonnæ ad 3 i. 30
Aquæ camphoræ

Misce.

A mixture of menthol and powdered spermaceti, in proportion of 15 grains to the ounce, is frequently used for the same purpose, as a snuff. Quinin is without honor, but Dover's powder is serviceable if the first symptoms of the rhinitis are discernible in the evening.

Chronic Hypertrophic.—The usual symptoms of this disease are nasal obstruction, accompanied by discharge anteriorly and posteriorly. In slight cases where there is very little obstruction a powder is prescribed composed of:

¹ Excepting one, the Central Hospital is the largest institution in the world devoted to diseases of the throat, nose and ear, having over 40,000 visits annually.

R. Potassium chlorat.	
Sodii biborat.

A teaspoonful (level) to be dissolved in half a tumbler of tepid water, and injected along the floor of the nostrils night and morning. After using, the nose must be blown, without holding it. As an accompaniment of this an ointment composed of ol. eucalypti gtt. xx, vaselin 3i is ordered, a little to be introduced into the nostrils after the wash. This treatment is not considered energetic enough to fulfill the requirements in the severe cases. Here, operative measures are demanded. When the tissues are permanently thickened, the condition is cured in one of three ways, viz., by the application of caustics, the use of the wire snare, hot or cold, or by the galvanocautery. Of caustics chromic acid has superseded all others. The hypertrophied turbinate is thoroughly cocaineized by the introduction into the nostril of a pledget of cotton soaked in a 10 per cent. solution of cocain. This causes complete anesthesia and shrinkage of all intumescent tissue that might otherwise interfere with the application of the probe to the spot diseased. After the cotton is removed the surface is wiped dry through a speculum with a cotton carrier. A flat probe, with the chromic acid fused on one side only, is then introduced and pressed against the selected spot. One side of the probe is kept clean so as to avoid touching the septum. Should this accident occur there is danger that a bridge may be formed between the septum and turbinate, and a probe is passed at intervals until the healing is complete. A few minutes after the application the acid is neutralized by an injection of a saturated solution of bicarbonate of soda and water. The slough is removed, in a few days, with the forceps, and a little of the pulv. potass. chlorat. compound is blown in. Of wire snares, no particular pattern takes precedence, the main object being to have one that will allow the hand to work out of line of the operator's vision. Cases in which the turbinates have undergone a kind of polypoid degeneration in front, or project largely into the naso-pharynx behind, blocking the choanæ, are regarded as desirable for the snare. These posterior hypertrophies often require great dexterity to encircle them with the wire and catch a hold. The method pursued is to pass the wire loop through the anterior nares along the floor, then with finger introduced through the mouth into the post-nasal chamber and by touch get the loop into position. When the galvanocautery is used it is never heated beyond cherry, else bleeding may occur. The same method described above for cocaineizing is followed. Flat or pointed burners are preferred, and the point should be thrust into the thickened tissue several times, according to indications. The same care is exercised to prevent touching the septum that was noted in describing the application of chromic acid. The spokeshave of one of the surgeons (Mr. Carmalt Jones), is not so largely employed as the acid, snare and cautery. The shave is a useful instrument in dextrous hands, but those less experienced find it hard to regulate the amount of tissue that may be taken off, the eye not being invoked.

Chronic Atrophic.—Most patients who apply for treatment in this affection do so because of the disgusting odor which makes them offensive in com-

pany. Cleanliness is the basis of all treatment. Crusts are immediately removed, and this is followed by a thorough washing with some antiseptic solution such as Dobell's. The removal of crusts is facilitated by the packing of the nasal passages full of cotton wool, which irritates the lining membrane and produces an abundant flow of secretion, loosening the scabs and enabling them to be removed by the forceps. A coarse spray of Dobell's solution follows, the nose-piece fitting tightly in one nostril, and from hand-ball pressure the stream runs in and comes out of the other nostril. When the crusts are adherent to the posterior parts a bent nozzle is passed through the mouth into the post-nasal chamber, and the spray thrown forward. The patient is then ordered to keep the nose clean by using the spray at home. Sometimes the pulv. potass. chlorat. compound is prescribed instead of Dobell's. An oily spray follows the wash the ones commonly advised being:

R. Menthol.	5ss.	2
Ol. Olive.	3i.	30
Misce.	Or	
R. Ol. eucalypti	gtt. xx.	120
Iodol.	grs. v.	30
Vaselin.	3i.	30
Misce.		

This treatment is not expected to effect a cure, but is given to render the nose free from odor and keep the patient from being offensive to those with whom he comes in contact. There is another form of treatment of these cases pursued by some of the surgeons connected with this hospital, and believed by them to be absolutely curative. The principle is to create irritation of the mucous membrane sufficient to change the atrophic process. Several plans are followed, but sometimes it is necessary to take the patient into the hospital in order to have the directions carried out. The generally adopted plan is to make the patient, nightly, stuff the nostrils with iodoform wool, after using the spray. One side is packed at a time, the stuffing alternating. He is made to sleep with it in place if possible. Another way is to paint the entire lining membrane, after cleansing, with a 10 per cent. solution of trichloroacetic acid, or with diluted tincture of iodine 1 to 7. Still another way is to take a small roll of canthos paper, and after the usual washing, a piece of the paper is cut an inch square, and made into a roll and introduced into the nostril, only one side being treated at a time. This is left in place as long as the patient can stand it, which is about twenty minutes. This treatment, and the ones by painting, are repeated every two weeks, but must be prolonged to accomplish good results, and continual spraying is required to prevent relapse. Constitutional treatment is directed in all forms of catarrh, but is considered secondary to local measures. Since the mental state of all victims of atrophic rhinitis demands stimulation, they are encouraged in every way possible and urged to persevere in their treatment.

Caseous.—This is an obstinate and rare affection in which cheesy and putty-like masses block the choanæ. The caseous accumulation fills up the sphenoidal sinus at times and is generally considered as due to caries of the ethmoid bone, but little is positively known of its pathology. The masses are carefully scraped out, and the sphenoidal and ethmoidal cells curetted, when this can be accomplished. The coarse spray is used persistently, and hygienic

and general constitutional measures prescribed. The disease is regarded as curable if properly and persistently treated.

Croupous.—In its relationship to diphtheritic rhinitis this disease holds a subsidiary position corresponding to that of membranous croup in the larynx. The treatment is rather tedious, since the membrane is very adherent. Alkaline washes are followed by forceps, and an oily spray. Sometimes the nostrils are provided with a lightly carded pledget of menthol wool, 5 to 10 per cent. Tonics and a change of air are often required.

VAGINAL OVARIOTOMY.

BY JOHN MADDEN, M.D.

MILWAUKEE, WIS.

Dr. T. G. Thomas, of New York, performed the first systematic vaginal ovariectomy in February of 1870. Before undertaking the operation he prepared himself by operating eight times upon the cadaver. He placed his patient in the knee-elbow position, secured by the apparatus of Bozeman. He passed a rectal bougie into the bowels for a distance of five inches "to prevent all possibility of the rectum falling into the line of incision," lifted up the perineum and posterior wall with a Sims speculum, seized the fornix vaginae between the rectum and cervix with a tenaculum, and, with a pair of long-handled scissors, made a longitudinal incision into the cul-de-sac "with one stroke." The tumor was then seized with a tenaculum, three small cysts ruptured and their contents evacuated, whereupon it was easily drawn into the vagina. The patient was now placed in the dorsal decubitus, the pedicle of tumor ligated with a double-silk ligature, cut off and the stump returned to the abdominal cavity. The incision was closed with a single wire suture.

Dr. Robert Battey performed the operation first in 1874, and in 1877 (Trans. Am. Gyn. Soc.) successful cases were reported by Drs. Gilmore, of Mobile, Clifton E. Wing, of Boston, and Goodell, of Philadelphia. In reporting his case Dr. Goodell mentioned a successful vaginal ovariectomy by Dr. R. Davis, of Wilkes-Barre, Pa.

In all of the cases here quoted the operation was done for the removal of an enlarged ovary, and are not examples of Battey's operation, which was introduced at this time. After the introduction of Battey's operation, however, a number of operators removed the ovaries per vaginam; but it is not possible to separate the cases belonging to each class.

In Europe vaginal ovariectomy never received any favorable recognition. Whether Hegar, following in the footsteps of Battey, selected the vaginal route for the performance of any of his cases of castration is not recorded. That he did so, is not likely. Olshausen in 1886 (Krank. des Ovar.), remarked that the operation had "never met with favor in Europe and seems to be quite generally abandoned in America, its fatherland." He quotes Mignon of having collected, up to that time, the literature of 113 cases. These cases, however, include all operations in which the ovaries were removed through the vaginal vault, including those in which destructive inflammatory and suppurative diseases had existed. Since 1887 this mode of operating seems to have been quite completely abandoned; for a careful search through a good deal of gynecologic literature published during the inter-

vening eight or nine years failed to discover the record of a single case,¹ and modern text-books dismiss the subject with a half-dozen lines. The complete abandonment of this method of operating is due more, perhaps, to the development of aseptic methods than to any other cause. Fifteen or twenty years ago an abdominal section was not made without hesitation and any method looking to an avoidance of wounding the abdominal peritoneum was looked upon with favor. At the present time the abdominal section has reached a degree of favor little short of an apotheosis. There can scarcely be any doubt, however, that in many cases the vaginal route is preferable to the abdominal. Certainly the operation is too valuable to be cast aside.

On the 8th of December last I operated through the vagina for the removal of a cystic ovary, and wish to contribute a description of the operation to the scant literature which now exists upon that subject. The patient was 42 years old, of a nervous temperament, poorly nourished, and gave a history of pelvic disturbance extending over a period of fifteen years. An examination disclosed the presence of a tumor occupying the left side of the pelvis, its lowest part reaching about the level of the internal os. There was no evidence of previous salpingitis, nor attachment of the tumor to surrounding parts; for when the patient was placed in the knee-elbow position the tumor escaped from the pelvic cavity entirely. The pelvis was roomy and the uterus freely movable; but the choice of method was influenced not a little by a lack of faith in being able to have strictly aseptic methods observed in the hospital which the patient had selected. After making the usual preparations, the patient was put in the lithotomy position, the vagina again thoroughly washed out, first with a 1:1,000 bichlorid solution, then with sterilized water, and the uterus exposed by means of perineal and vaginal retractors. The lower lip of the uterus was then seized with a pair of strong bullet-forceps, drawn down to the vulva and given to an assistant to hold. In the same hand the assistant held the nozzle of a fountain syringe filled with sterilized water, to which had been added bichlorid of mercury, 1:5,000, and chlorid of sodium, 6:1,000, for continuous irrigation. A transverse incision was now made through the lowest part of the cul-de-sac, close to the uterus. The incision was begun with the scalpel and made large enough, at first, only to allow the insertion of the index finger tip. The bleeding of the afferent uterine vessels was stilled by the introduction of a stitch. The incision was enlarged with a pair of blunt-pointed scissors, a stitch being taken each time to prevent hemorrhage (Fig. 1), before the tissue was cut. The method adopted is almost exactly like that used by Martin for vaginal extirpation of the uterus, whence this illustration is taken.

After making the incision about 2½ inches long, the finger was introduced into the pelvic cavity and the tumor found to be entirely free of adhesions. The tumor was now seized with a pair of volcellum for-

¹ Since this was written my attention has been called to a case reported by Staude, of Hamburg (Monatsschrift für Geburtshilfe und Gynäkologie, Bd. II, Heft 4). In this case the tumor was not discovered until labor had begun, when it was felt crowding the posterior wall of the vagina forward. Unable to push it up, Staude opened it, allowing the escape of considerable fluid. He then drew the tumor into the vagina and ligated it together with the tube; but the labor pains came on with such strength and rapidly that he was obliged to finish the operation after the child was born. He closed the incision with a catgut suture. The patient made an uninterrupted recovery.

ceps, drawn down, two of the cysts ruptured and their contents evacuated, when the tumor was easily drawn into the vagina. The pedicle was ligated, cut off and returned to the abdominal cavity. The pelvis was thoroughly washed out with sterilized water, the incision was left open, several strips of iodoform gauze were put in for the purpose of absorbing whatever moisture might be left, and the vagina was also filled with the same material. The tumor, after being in alcohol several weeks, now measures $6\frac{1}{2}$ inches in lesser and $9\frac{3}{4}$ in greater circumference. The time occupied in the operation was a little less than thirty minutes, and there was absolutely no shock following it. A profuse uterine hemorrhage, however, occurred on the third day after the operation, and on the fourth day there began septic disturbance, resulting in the formation of a pelvic abscess which apparently began in the pedicle stump, and made the convalescence tedious. The point of infection, however, was easily reached and the abscess thoroughly drained through the vaginal incision.

The employment of the vaginal route for the removal of ovarian tumors certainly has great

INCISION INTO CUL-DE-SAC.

limitations. A large tumor can not be removed in this way, especially if it be solid. Dr. Thomas would limit it to cases in which the tumor was "not larger than the head of a child a year old," but this must necessarily depend upon the peculiarities of each individual case. It is obvious that a simple cyst filled with serum only might be easily removed, while a multilocular cyst containing much semi-solid matter and connective tissue, though comparatively small, could not be removed in this way. Firm adhesions, too, especially between the tumor and the intestines, would make the operation impracticable.

The ovaries are not as easily accessible through the vaginal vault as they are through an abdominal incision, and if the soft parts be rigid and the pelvis narrow, these conditions may make the operation difficult; but if the uterus be freely movable the difficulties are not insurmountable. Furthermore, this method of operating can be abandoned for the abdominal route at any time during its progress, should it be thought for any reason to be impossible to complete; for the vaginal incision does not add to the gravity of the abdominal operation. It may, indeed, serve a useful purpose in permitting perfect

drainage. The advantages of the vaginal operation are, first of all, that it is not followed by shock. The short, simple incision, involving only the thin septum between the vaginal vault and floor of the cul-de-sac, produces little or no impression upon the nervous system, while the abdominal incision is often followed by profound nervous depression. The operation leaves no sensitive scar and there seems to be no danger of subsequent hernia. Upon this latter point I wish to quote Dr. Leopold Landau, of Berlin. He told me (in October of 1893) that that he had made over 200 vaginal hysterectomies with clamps and that he had never had a prolapsus of the intestines and had never seen the operation followed by a hernia. Furthermore, septic infection is certainly more dangerous where there is a large abdominal wound to become involved; aside from the fact that the abdominal peritoneum is much less tolerant of septic invasion, and much more speedily and frequently terminates in death than when only that of the pelvis is involved; and lastly, the point of infection is easily reached through the vaginal incision if suppuration does take place. Of the recorded cases which I have been able to find, none have terminated fatally. Olshausen (*Krank. des Ovar.*), in his discussion of this operation, states that Mignon collected from literature 113 cases, with 77 recoveries. As these cases embraced all kinds of conditions, some of profound inflammatory and suppurative disease, they should not be discussed under the head of vaginal ovariectomy. To sum up, the writer believes that in the case of a small, non-adherent tumor of the ovary with a normally mobile uterus, the vaginal route should be selected for its removal.

63 and 64 Sentinel Building, Milwaukee.

THE SANITARY INSPECTION OF FACTORIES.

Read before the New Jersey Sanitary Association at their Twenty-first Annual Meeting held at Atlantic City, N. J., Dec. 6 and 7, 1895.

BY O. W. BRAYMER, A.M., M.D., PH.D.

President of the Camden City Medical Society; Member of the American Medical Association; Fellow of the American Academy of Medicine; Fellow of the Military Order of Surgeons of New Jersey; Member of the District Medical Society of Camden County, the Medical Society of New Jersey, the New Jersey Sanitary Association, Etc.

CAMDEN, N. J.

While a study of the legislative enactments on factory inspection, as found in the labor laws of our States and Territories, teaches us that our legislators and health authorities have not entirely neglected the subject of sanitary inspection (since in a few of our manufacturing States there are laws good so far as they go), yet it is very evident that no great effort has been made to improve the sanitary and hygienic environments of the workingman, and create the best possible conditions for his health and work; conditions which conform to the scientific knowledge of our age. It would appear that nothing had been done beyond what necessity had enforced. No scientific knowledge of sanitation seems to have been promulgated among our factory owners and the working people of our country.

It is true that laws have been enacted regulating the age at which children can be employed in mills of various character, yet from going through these mills and looking at those working therein, we feel doubtful as to whether these laws are being lived up to. It is also true that the working hours of men, women and children have been established by law; also ventilation, water-closets, and accidents from

machinery have been considered, and recently in New York State a very good law has been enforced regulating the sanitation, of bakeries both to promote health and cleanliness among the employes and also to give the public a better and purer article of food. It is also a fact that several of our States have factory inspectors, yet after reading the laws governing the same, and noting the amount of compensation allowed for the work, we are, very doubtful whether much good is being accomplished. We can see in all this nothing especially to better the sanitary conditions of the workman, or the public. About all the functions these inspectors have, is to order the rules of the department posted in the factories, and in some few instances, when complaints have been made, they may make an effort to remedy the existing wrong. This is not the kind of law we want; it is not the kind of legislation that protects the workingman and shield him from the diseases of his occupation and frees the masses from the danger of filthy products sent upon the market, or the contaminated air which comes from poorly managed factories.

We have a great problem to solve when taking up a subject of this character, and it is impossible in the short time allotted to me to do more than give you a few scattered ideas in reference to the solution.

Statistics show that one-fourth the deaths in Great Britain occur from pulmonary consumption, the majority of which can be traced to the breathing of dust-laden or impure air. Some foreign countries have taken up this subject in a more rational way than ours. They have made it a national question, and to-day we can point to England, France and Germany as having very good laws, the enforcement of which has done much to benefit the workingman and the public. We also are pleased to know that the medical profession, especially in these three countries, has taken a great interest in the subject of factory sanitation, and some most excellent works, describing the diseases of different occupations, have been published. In looking over the laws of our States, I was impressed with what seemed to be a fact, viz., that notwithstanding considerable had been accomplished concerning the inspection of factories, very little, if anything had been done to establish an inspection and regulation of a true sanitary or hygienic nature. While there are laws bearing on the subject they are only of a general character and do not cover the ground in a way to do much good. For example they take up the subject of guarding against accident by machinery and fire. These are naturally to be guarded against by the mill owner for personal reasons; legislation is not needed, since any such accident would cause more or less loss of time and money to him, and further annoyance might be anticipated from suits for damage, etc.

In the case of injury and disease from unhygienic conditions this will not hold true, because it does not interest the average capitalist to correct these things. In the majority of instances he overlooks them entirely and when disease overtakes his workmen they are allowed to drop out and fresh hands are taken on without any or little thought concerning the cause of the disease or how it might have been prevented.

The details which enter into the regulation of sanitation in a factory, to the average employer, only interest him in so far as they have to do with the amount of salable products put on the market from

his place of business. Sanitary science may have little to do with this, but may have everything to do with the health of the workmen. The capitalist's motto reads, "The maximum gain for the minimum expenditure." The life of the workingman is of little importance in his sight. In looking over the last census report of the United States, we find that over five millions of our population, ten years of age and over, are employed in factories; of these about 80 per cent. are males and the balance females. A vast army of citizens who go to make this country stand high in the list of nations as a manufacturing people! Yet very little has been done to furnish protection, by sanitary regulations; little care has been taken to guard these millions from their unseen yet deadly foes, the bacilli of disease, that are cutting them down with a greater force than would the missiles of a battlefield in times of war. Can we, as sanitarians, be idle and see this havoc go on? Should we not take hold of this subject and with one mighty, united effort strive to protect this hard working host of humanity? We must remember that these millions of beings do not only represent themselves, but they are an illustration, a reflection of future populations; and they determine what the health and status in society shall be of subsequent generations; their children and their children's children.

That unsanitary and unhealthy occupations do cause degenerations in whole communities and produce a stunted and poorly developed people both mentally and physically is no visionary thought. It has been proven by many investigators and as an example let us cite the English manufacturing district, where competent authority states that of 2,000 children, who were working in the mills, only 341 were well developed, and scarcely sixteen of the whole lot could be called handsome, and these latter were most every one of them not natives of the colony but girls imported from Ireland. What would the progeny of such a population be? Certainly no better mentally or physically. These unsanitary conditions in factories and among factory people not only cause a lessening of health and intellect but also lessen the amount and quality of goods produced; and in large manufacturing districts, this would be even more marked than it is, were it not for the fact that new material is being constantly taken in, from the country and neighboring locations, which raises the percentage of health and consequently lowers the rate of defect.

In all the factories visited by me some attempt seems to have been made to favor sanitation, yet it lacked that system which follows wisely enacted and righteously enforced law. It wants more science at the fountain head to give life to the stream. Especially is this true, with reference to water closets, ventilations, cleansing of floors and walls, drinking water and the personal hygiene of the workers. Improvements in machinery and method of manufacturing have done much to benefit the workman. Electric lighting has caused a great sanitary gain; not only because it gives better illumination, but also because it lessens the danger from fire and explosion, and the atmosphere is not impregnated with the products of combustion and it also reduces that oppressive heat which originally was one of the results of illumination by means of oil or gas.

We all realize that it is very important that ventilation be looked after and in no factory should there

be less than 250 cubic feet of air space for each individual workman; yet so far as I know, only two of our states have such a clause in their factory laws. Then it must be considered that with all the ventilation known to science, there are many kinds of industries where a certain amount of danger from dust still exists as in flour and rag mills, pottery polishing and china scouring factories, etc. In all such factories employees ought to be compelled by law to wear respirators and at the same time every effort should be made to devise means to carry off the dust.

Then again, this sanitary inspection has not only to do with the people employed in the mill, but, as inferred before, the surrounding population; the inhabitants living near the place of manufacturing should be protected. Places where old fats and hides are being utilized, and chemical works are continually annoying certain of our committees by various forms of offensive odors more or less deleterious, coming from their midst, should be compelled to regulate the amount of stench thrown off into the air. The steps which England has taken, and the results, have proven that many of the causes of air pollution can be removed.

But when such legislation is obtained, unless there is a proper head to enforce the law it is of little or no avail. It must not be inferred that sanitary inspection would tend to restrict the manufacture of chemicals and like substances. Good laws would only set a limit to the amount of obnoxious gas to be discharged into the atmosphere, and in England it has been proven that the enforcement of the alkali act has not only benefited the workingman and those living in the neighborhood, but it has caused improved methods of manufacturing to be invented and materials to be saved. We must have the aid of the powerful hand of the law if we hope to accomplish anything in this line. One of the first laws of nature is self preservation and Blackstone says "no human laws are of any validity if contrary to the laws of nature." We contend that it is in accordance with nature's law to create and enforce sanitary legislation. Our fellow men and ourselves must be protected.

Many are the instances of filthy customs allowed in factories which need our attention. As an example let us cite the moistening of cigar ends and wrappers with saliva—a detestable habit which should be prohibited. Again, tenement house or sweat shop clothing must be closely guarded and the employees and work rooms kept clean, and all goods coming from such factories should be labeled so that the dealer and consumer might protect themselves. That bakeries be kept clean is of the highest importance since we believe that in this occupation there is a great danger of becoming diseased. The very thought of filth and carelessness allowed in some of our bake shops is enough to create disease. Strict legislation should be enforced to compel this class of workers to be clean both in person and in their work.

Capital secures legislation to protect its interests regardless of the conditions of the workmen employed, while at the same time very often the only capital possessed by the workingman is his health and strength. Certainly the State owes the employees as much protection as the employers. Desire for increased wealth on the part of the owner of factories often causes a reduction of the working force, and an attempt to reduce breathing space may be made, to curtail the extra expense of building. In some in-

stances the workers remaining will not complain if their wages are not reduced. They may be ignorant of the danger that lurks about them, they may not understand nature's laws, which condemn in no mild words over exertion and poorly ventilated rooms; yet their health is at stake and it is for this reason that sanitary science should interfere and save these beings from an untimely death. If you take the time to look up the statistics on this subject you will find that there is a very great increase of lung disease among those people who work in factories, nearly or quite 100 per cent. more than among those working in agricultural districts. Observation shows that mineral and metallic dusts are the most dangerous and one reason why the evil effects of breathing dust-laden air is not more apparent to workmen is because they are slow in action. Yet the effect is in the end deadly. The inhalation of dusts, mineral, metallic and organic not only cause fatal lung disease, but offensive and poisonous gases, sudden changes from hot to cold or vice versa, will cause disease, and often death. Such diseases, if not fatal, rob a man of health and strength and thereby lessen his chances of self-support; and since they are in the majority of instances avoidable, it seem criminals for our authorities to allow them to go on without a greater effort for their prevention. It is not only the individual but the community and state that loses in allowing such evils to exist.

These subjects require the careful attention of our legislators and health authorities and every possible effort should be put forth to bring about the needed change. Naturally the question arises: How can this be accomplished? Let me answer: Educate the masses; teach sanitary science to the child and when he becomes a man he will put his knowledge to good use. When the public becomes more enlightened concerning sanitary science; when our school authorities are awakened to the fact that hygiene and sanitation, both of the individual and the community, are among the most important foundations of learning that can be instilled into the youthful mind; and when they learn that it is for the interest of every one that these subjects be taught in our public schools and colleges, and that this instruction be given not by one who has little or no idea of the science, but by competent medical men, appointed by each school commission, then will a demand for better sanitation in factories be exacted.

To know how to read, write and cipher is not enough for that child who has to leave school at 12 years of age and go forth to earn its living. He should also have a fair knowledge of self-preservation, as unfolded by sanitary law, physiology and hygiene. Our people are filled with a false modesty from which they must be purged. Every child, both male and female, should at the age of puberty be taught the important laws of life and procreation and be shown how to escape the ills which befall those who live unclean lives and be guarded against the sins of immorality. The time is coming when laborers will strike for hygienic surroundings as well as for money. They will learn that "health means wealth" and act accordingly. We, as sanitarians, must look deep into this subject of sanitary legislation. No matter what elaborate laws may exist on the statute books, unless there is a well-organized system for their enforcement, by a carefully chosen board of sanitary inspectors; men selected for their

ability as sanitarians, not for political prestige; men versed in medicine and sanitary science, not politicians, principally interested in drawing their salary; unless these particulars are looked after, we say our purpose for a betterment of the workmen in our factories will not be accomplished. These laws must be broader and take in a greater scope than any ever enacted in this country heretofore.

It is not sufficient that machinery be so guarded that injury will be prevented; it is not enough that fire escapes be provided and water closets and good drainage be established. All these things are essential for the welfare of the workers in the factory, yet thousands of other subjects are crying for our attention. These urinals and closets must be well lighted, ventilated and disinfected. This disinfection should be done daily after the room has been thoroughly scrubbed. These closets should be arranged separately and in different parts of the building for the two sexes. Investigation has shown that notwithstanding these matters are looked after in a measure in most factories, yet this attempt is only a poor excuse for doing an important work. The stench emanating from most of these places leads us to believe that no powerful hand directed by a sanitary mind is superintending the cleansing and disinfection of these places. Instead of a factory inspector with power to employ deputies, as the law provides now in different States, we want a sanitary inspector, a thoroughly educated and competent man, who will have a deputy in every district, who will look into the workings of the factories; have a keen insight and observe the wrong, and will enforce the law.

Not only the mill itself and the owner should be kept on the right track, but the habits of life of the workmen must be looked into, and where disease is being contracted because of ignorance, the people should be brought to light. Among the important necessities of every factory is a good, pure supply of drinking water, and each employee should own and be compelled to use a drinking vessel. The miscellaneous use of a common drinking cup is often the cause of the spread of disease, not only in factories but in our schools and places of public assembly. The fact that our churches are adopting individual communion cups has been a great step in promoting sanitation. It shows that our people are interesting themselves in the right direction. There should be wash rooms in every factory, so that employees could change or adjust their clothing and wash their hands and faces. Indeed where the work is very dirty, not only should a place be set aside where those who are compelled to carry their dinner could eat with comfort, but baths should be provided, so that the body could be cleansed before going home. Seats should be provided so that especially females could sit down when not actively engaged.

When one goes into a factory, as we have done not long since, and observes the tobacco juice and corruption being expectorated on the floors, and then notes the poor ventilation, he will be even more impressed, as I was, with the fact that cuspidors should be provided, filled with some antiseptic fluid, and a rigid rule enforced, compelling the same to be used. These receptacles should be cleansed daily. Such a procedure would prevent the spread of many diseases, the germs of which are contained in this filthy sputa, and are carried in the air when dried. Our legislators should feel that without reference to

profit or loss, the first thing in every factory should be, to see that as great a chance as possible be given the employe to maintain his health. It may be claimed that it is not practicable for our government to take hold of this subject. Such a protest would appear *feeble*. Other countries have enacted good laws and have kept them in force. Our own government looks after its different departments and protects her citizens from wrong in every land of the earth. Why not some such attention to the health of the people. When we look at the increased death rate from lung and other preventable diseases arising from badly regulated factories we think of that line which runs:

"Hark, from the tomb a doleful sound, mine ears attend the cry."

Thousands, yes, tens of thousands of our fellow citizens are yearly going down to untimely graves simply because our factories are not properly looked after by sanitarians. Let us apply the remedy and prevent this premature decay. Educate the people; begin in the public schools and in a few generations we shall have a population of sanitarians, create a Department of Public Health, and let its power and influence be felt in every city and hamlet of this broad land. Elect men to office, both National and State, who understand the principles of sanitary science. Then with a public backing them that demand such laws, they will be able to see the necessity and will have the courage to enforce sanitary legislation.

THE RELATION OF ADENOID VEGETATIONS TO IRREGULARITIES OF THE TEETH AND ASSOCIATE PARTS.

Read in the Section on Dental and Oral Surgery, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY GEO. F. EAMES, M.D.

BOSTON, MASS.

Your attention is invited to a few preliminary statements as indicating my position in relation to the subject of which I am to speak.

1. While mouth-breathing is usually attendant upon adenoid growths, this is not *always* the case, while, on the other hand, mouth-breathing may exist without the presence of adenoids, or it may be due to a chronic hypertrophy of the turbinated bodies, or some septal deformity.

2. The adenoid growth rarely fills the pharyngeal space so as to obstruct breathing, but mouth-breathing results from irritation which it produces.

3. Mouth-breathing does not produce adenoid vegetations.

4. Mouth-breathing does not cause irregularities of the teeth.

5. I have examined many cases presenting deformed arches and irregular teeth, in which no adenoids existed.

It is argued by G. MacDonald, that nasal stenosis is a constant factor in post-nasal growths, and that this being the case, "as long as respiration is conducted through the nose, there is, of a physical necessity, a diminution in the barometric pressure behind the seat of stenosis. This inevitably results in more or less overfilling of the blood-vessels which, in its turn, leads to hypernutrition and hypertrophy." It is obvious, that when the diaphragm is depressed, the mouth closed, and the nose partially closed, there is more or less suction produced which would invite

blood in extra amounts to the pharyngeal region, but according to my observations, patients breathe through the mouth, both by instinct and force of habit, even when it is possible to breathe through the nose. The swollen turbinates, with their rich supply of nerves, readily convey a sense of suffocation to the brain, and the mouth is immediately opened. I have repeatedly found children breathing through the mouth, and upon request to breathe through the nose, they have been able to do so, but as soon as their attention was drawn in another direction, the mouth opened and mouth-breathing was continued. Moreover, the mouth opens so readily, upon so little provocation from the nasal irritation and stenosis, that it does not seem possible that sufficient "diminution of the barometric pressure" can be produced in the pharyngeal vault to cause a growth of tissue. Again, if this be true, we ask why the growths are so often pedunculated, while the pressure is exerted equally in all directions. This view also necessitates nasal stenosis to begin with, but it is generally understood that the enlarged turbinates are the result, not the cause of adenoids, and observation shows that the nasal obstruction gradually disappears after the removal of the growth. Again, this will not account for the congenital growths, and those in infants whose oral respiration has only been established a few weeks or months; and still again, those cases of nasal stenosis of long standing in which there is no adenoid hypertrophy. If it is true that this "diminution of barometric pressure" acts also to increase the size of the faucial tonsils, how shall we account for many cases of post-nasal adenoids, in which the faucial tonsils are normal? Their growth and development is acknowledged to be on the same principle, they have physiologic limitations in common, and it would seem reasonable to assign a cause common to both. It has been said that adenoid growths in the pharyngeal vault cause irregularities of the teeth. I do not believe this to be the case, but rather that the dental irregularities are only another expression of the same cause that operates to produce the adenoid growth; in other words, there is one cause common to both, yet this cause may not be able in all cases to produce both. The bone developing vital movement may be strong and active by inheritance, while the lymphatic glandular system is weak. Deformities of the hard palate, forming the dental arch, are frequently associated with adenoid growths, but not always, as many would give us to understand. There are various reasons given concerning the origin of these irregularities. For instance, it is said that a so-called high arch, or V-shaped arch is a diagnostic sign of adenoids in the pharyngeal vault. The late Dr. F. H. Hooper in his pamphlet on "Mechanical Effects of Adenoid Vegetations" says, "The hard palate, from the constant atmospheric pressure within the mouth, is pushed upward." It is difficult to see how there can be a constant pressure within the mouth while it is open and the air is free to move either in or out. The air must be confined in a given space, and a force exerted, in order that pressure in any direction be made. Therefore we can not believe that this deformity of the arch is due to atmospheric pressure caused by nasal stenosis.

The theory of David accounts for the deformity of the hard palate in persons suffering from nasal stenosis, by a partial vacuum produced in the nasal cavities and upper pharynx by the act of swallowing.

The atmospheric pressure remaining the same in the mouth, its roof is pushed upward. It is difficult also to reconcile this theory with the writer's view of the case. In the first place, it must be a rare case in which the nasal stenosis is so perfect that a partial vacuum should be produced behind it. It is well known that in the act of swallowing, the tongue presses forcibly against the roof of the mouth from before backward, the soft palate is slightly raised, as the bolus of the food passes it, the posterior pillars of the soft palate then contract on either side of the uvula, forming a nearly perfect valve which, with the application of the posterior wall of the pharynx to the superior surface of the soft palate, forms a successful barrier, protecting the posterior nares. The necessity of this, as well as proof of this function, is shown in cases of paralysis of the soft palate, in which liquids swallowed regurgitate into the nose. Now, the act of swallowing is momentary, and the muscles contract firmly, and it does not seem possible for this temporary diaphragm to be so pulled downward as to cause partial vacuum in the nasal cavities; moreover, immediately after swallowing there is a reaction, the breath being held during deglutition, it is expelled with some force through the nose, or into the nasal cavities, the mouth being closed in the act of swallowing. If the air does not find exit through the nose, the mouth does not open until after considerable pressure has been exerted in the upper pharynx and the nose. This may be demonstrated by occluding the nose with the thumb and finger, and performing the act of deglutition. Again, if deformities of the hard palate are caused by the withdrawal of atmospheric pressure on one side, and maintaining it on the other, it would seem that as the pressure bears on all parts equally, the palatine arch should be pressed upward equally high in all directions. This is not the case always, for example, model 1, shows the case of Mr. C. aged about 39 years, with a large adenoid growth in the pharyngeal vault, but one side of the hard palate is much higher than the other side.

It is said that mouth breathing necessitates a constant dropping of the lower jaw which, in so doing, causes pressure of the masseter and other muscles upon the buccal surfaces of the upper teeth and consequent flattening of the lateral alveolar arches, and the projecting forward of the cuspids and incisors. I can not believe that the dropping of the lower jaw produces pressure on the teeth in the superior maxilla. The lower jaw is approximated to the upper teeth principally by the masseter, temporal, and internal pterygoid muscles, and when the jaw drops by the relaxation of these muscles, and with it other muscles and tissues of the face, unless the mouth be open to the fullest extent by the action of the platysma myoides, digastric and other muscles, the tissues of the cheek are not put upon the stretch; in fact the finger can be easily passed in between the teeth and jaw without being sensible of any pressure upon it, provided the mouth is not opened widely; moreover it seems reasonable to conclude that the jaw is held suspended, not by the cheeks, but by the masseter and accessory muscles. The cheeks cover the jaws and teeth loosely, with tissue to spare, and will, as a rule, admit of the jaws being opened to a considerable extent without separating the lips, or stretching the cheeks, which is the case during sleep; therefore when the lower jaw relaxes sufficiently to let the air in

through the mouth, it can not put the tissues of the cheeks on the stretch, or draw them tightly against the teeth. Both observation and experiment will show that it is only necessary to open the lips slightly, in order to allow sufficient air to pass in by the mouth, and that all the tissues concerned are in a relaxed condition while the mouth-breathing is going on. In order to demonstrate this, I have made a number of experiments to determine the pressure of tissues and muscles against the teeth. The device which I have found most successful, is one which I take pleasure in passing around for your inspection. The instrument will explain itself. At first I intended for the little pointer to make a tracing, but I find that unnecessary, for the pointer may be observed while the mouth is being opened. The use of this apparatus confirms my views as above expressed. Moreover, the anatomy of the parts involved bear the same testimony upon careful observation and study. Notice the fact that a straight line drawn from point of origin to insertion of these muscles, would not touch the teeth. A profile view shows the fact that the masseter extends no farther forward than the second molar, while the other muscles concerned do not come as far forward as this. It has been suggested privately by several prominent gentlemen here present, that this demonstration was unnecessary, that it is absurd to suppose that the pressure of the cheek causes a narrow arch; but the others have differed from me publicly, and I then made a vow that I would make a demonstration upon which my opinion would either stand or fall, and I think I have now done it, and that my opinions as expressed, have been substantiated.

Bazin is quoted as advancing the idea that the weight of the tongue in the roof of the mouth would tend to expand the lower jaw beyond its normal limits. I would suggest, however, that if weight is the expanding force, how can it press laterally, since gravity would carry the tongue downward into the floor of the mouth, which would rather draw the sides of the jaw together than otherwise. But if it be the muscular force of the tongue, then it is easier to see how the teeth might be pushed outward. But here is a case, Model 2, Mrs. H., aged 30, with a history of mouth-breathing from infancy, with a marked contraction of the lower jaw, the bicuspid closing entirely inside their would-be antagonists. The nasal breathing is fairly free at the time, yet mouth-breathing is continued, partly from habit, and partly from a mild chronic, nasal catarrh. There are no adenoid growths or enlarged tonsils; there may have been in early life, but the one thing to be noted is, the habitual mouth-breathing did not expand the lower teeth in this case. Dr. Henri Chatellier, of Paris, calls attention to the bones of the head and face, consequent upon obstructed nasal respiration. He points out that the air cavities, as the frontal, sphenoidal, ethmoidal and maxillary sinuses being normally in communication with the air, cease to develop when the circulation of air through the nose is interfered with, and hence dimensions of the face are altered. The only article on this subject, written by a practicing dentist, which in any sensible degree reaches the truth and demonstrates it, is by Dr. E. S. Talbot, of Chicago. I believe the ideas which he thus expresses, to be based upon a correct principle. Dr. Talbot says: "There are many cases of contracted arches where mouth-breathing does not exist, there

are also many cases of normal arches where it is present." I have cases, seen by a number of competent witnesses, to show that the above statement is entirely correct.

I now wish to present two cases, both having marked adenoid growths and consequent nasal stenosis and mouth-breathing, but the dental arches present a striking contrast; models 3 and 4. Model 3 represents J. H., aged 13 years, upon whom I operated Nov. 4, 1893, removing a large quantity of adenoid tissue. In this case there was defective speech, the usual dullness and deafness. After the operation, the first improvement was shown in the hearing in two weeks, the speech was slightly better in four weeks, and the nasal stenosis is decidedly lessened. The marked feature in this case is the broad and regular dental arch. The other case, E. F., model 4, aged 9 years, was operated upon a week later. The symptoms were about the same as in the case just described with the exception that there was very little deafness. Compare the dental arch with No. 3, narrow and deformed arch.

Marked adenoid growths are sure to produce mouth-breathing and more or less nasal stenosis, but irregularities of the teeth, and deformities of the arch are not at all certain to follow as a consequence, but are rather companions, due to a common cause. Dr. Talbot further says that in most cases, the cause of these deformities is an arrest of development of the bones of the nose, and this produces mouth-breathing. While there may be an arrest of development of the bones of the nose, I would call attention to the fact that the opposite condition exists as to the turbinated bodies, which are hypertrophied.

As long ago as 1879 there appeared a paper in the *Philadelphia Medical Times*, by Prof. Harrison Allen, in which he says: "Inasmuch as the face is the result of the lateral visceral half arches joining the median structures, projected from the front of the brain-case, it follows that if there is want of harmony between the two genetic movements, errors of symmetry will readily occur." Explanation may thus be given of asymmetry of the nasal chambers, the external nose, the two halves of either of the dental arches, entirely apart from the acquired defects in the same localities. Applying this hypothesis to practice, Dr. Allen had recognized a well-defined group of cases in which the nasal chambers remained, from birth, partially or entirely occluded. Also that cases of obstinate nasal catarrh in children from 7 to 18 years of age, in whom the upper permanent incisors were overlapping and convergent, the two halves of the upper dental arch more or less V-shaped, the tonsils tumid, the roof of the mouth with a high narrow vault, the cause was deep lying and congenital, and affected all the structures of the face. Dr. Allen has frequently noted the way in which the dental arch was narrowed and elevated in adults, in whom no history of either adenoid disease or nasal obstruction was given. It should be noticed also that the upper incisors approach the vertical position, sometimes overlapping, in many cases of adenoid disease, while in thumb-suckers these teeth protrude from the mouth.

In a clinical lecture delivered before the First District Dental Society of New York, Dr. Allen describes a case which is instructive, showing the possibility of the Hutchinsonian, or an allied deformation of the teeth, occurring without a history of syphilis or scar-

latina. that oral respiration was established as early as the fifth year, due to a large adenoid growth, that the teeth were congenitally deformed, that this congenital deformation could hardly be caused by oral respiration established at the fifth year. The following is a description and remarks concerning the above case as given by Dr. Allen:

"A lad in his tenth year lately came under my observation for difficulty arising from oral respiration. He was the son of respectable parents. The father denied the taint of syphilis, and did not exhibit, upon examination, any sign of the disease. The child's mother died of phthisis a short time after his birth, and he had been brought up most carefully and intelligently by a nurse who is acquainted with his clinical history from the time he was born. The child has always been delicate, especially in the functions of digestion and assimilation of food, but there was entire absence of the ordinary signs of syphilis. There was no deformation on the top of the head (which has been described as natiform). There were no fissures in the skin at the nostril or at the angles of the mouth, no cloudiness of the cornea, no traces of previous eruption of the skin, nor evidence of periosteal disease. At the fifth year it was observed that oral respiration became established and there was also a disposition to take cold easily. Examination of the pharynx revealed the presence of a large adenoid growth pendant from the roof. The palatal arch was high and narrow, the obstruction to nasal respiration was absolute. The nasal septum was irregular, apparently due to enormous thickenings of the maxillary crests. The teeth presented all the characters of the Hutchinsonian deformity, excepting only that the lateral incisor teeth were not pegged. After the removal of the adenoid growth, nasal respiration was reestablished. Now what, in all probability, has been the order of events in this case? The clinical condition which brought the child under my care was not announced until the fifth year. Evidently this was not the first factor. So far as the shapes of the teeth are concerned, they must have arisen at a period certainly not later than at the time when the enamel organs and the dentine bodies were being adapted one to the other. In a word the shapes of the teeth as seen at the tenth year, were congenitally deformed.

"In the next place, the maxilla, especially in the alveolar region, must have been changed by the presence of these mal-formed teeth. It is scarcely likely that the establishment of oral respiration at a period so late as the fifth year should cause an elevation and narrowing of the palatal arch and hyperostosis of the maxillary crests. If this position be accepted, a narrowed, high, palatal arch, with thickening alveolar processes, would be just as apt to arise because of prenatal forces (the same which caused the deformation of the teeth) as to be created by the establishment of oral respiration."

We have leaned too much toward the faulty function last named, in attempting to explain this deformation, and not enough, at least in my judgment, to causes which are in operation at the time the teeth are being developed in the maxilla.

Gentlemen, the evidence is all in. I only wish to call your attention to other models which I pass around; they are all cases in which large adenoids were present. You will notice that a number of these casts show a fairly well-formed arch. I may say, also,

that I have operated upon many other cases, removing a large quantity of adenoid tissue, in which the arches were well-formed. I make this statement to show what has not been shown before, to my knowledge, namely, that a large number of adenoid cases present well-formed dental arches.

ECTOPIC GESTATION—REPORT OF A CASE.

Read before the Champaign County Medical Society, Sept. 18, 1895.

BY JOHN LAUGHLIN, M.D.

RANTOUL, ILL.

My reasons for reporting this case are because of many extraordinary conditions that maintained in its ten months' history and the remarkable recovery, the completeness of which was demonstrated by an operation for a complication.

Mrs. E. N., aged 36, the mother of four children, the youngest 4 years of age; no miscarriages. Her menstruation began in her sixteenth year. The flow was abundant and it came about every three weeks. Twelve years ago the menstruation disappeared for four months. A tumor came in the right lumbar region and it was aspirated of a large amount of offensive material by Dr. McClure, now deceased.

Her health continued fair until the fall of 1893. She said her menstrual periods were a little more prolonged and painful than common and a physician was consulted. In November, while going to church, she had a sudden attack of abdominal pain accompanied by weakness. After stopping at a relative's house for a few hours she returned home and afterward suffered from painful and irregular menstruation as before. I first saw the patient June 28, 1894. She complained of pelvic pain and menorrhagia. Urination was painful and frequent. The pulse and temperature were normal. The abdomen was tympanitic. There was a badly lacerated perineum and a bilateral laceration of the cervix. The uterus was enlarged, retroverted, fixed and, with the surrounding organs, so exquisitely tender as to prohibit a thorough examination. My diagnosis was endometritis with pelvic peritonitis. After a few days' treatment these symptoms subsided, and I did not see the case again until July 15.

The same conditions were present except that menstruation had ceased, and it did not reappear until near the end of her sickness. There was also retention of urine, and from that time till convalescence it was drawn with a catheter two or more times a day. Urinary analysis showed nothing abnormal. August 4, the amount of urine began to diminish, and for four weeks not more than from one to six ounces was passed a day. Some days there was complete suppression. A painful fluctuating tumor came in the right lumbar region, gradually increasing to four or five inches in diameter.

My colleague, Dr. J. C. Harmon, and Dr. S. M. Wylie, of Paxton, Ill., were called in consultation. Our united opinion was that we had a hydronephrosis due to occlusion of the ureter either by calculi or by pressure of a tumor. And since the patient said that certain small hard objects had been passed with the urine, we thought probably the former was the true cause.

Through the month of September the history continued as follows: On the first there passed from the bowel a pint or more of liquid containing blood, mucus, pus and portions of the mucous membrane of

the bowel. On the afternoon of the third a messenger reported her suffering great pain and very weak. A catheter was passed and two pints of urine drawn, and in four hours a total of five pints. It contained considerable pus and blood and was very offensive. The tumor was very much reduced in size. The diagnosis of hydronephrosis was confirmed, but the cause was yet in the dark. Two hard grayish masses the size of peas were assisted out of the urethra on the eleventh. They had the appearance of phosphatic calculi and were so considered at the time. No more were passed until some time in October, and then without the covering of urinary sediments that were on the first ones. They looked like the ends of the long bones of a stewed chicken. Then they followed in large numbers, each separate one following the same painful course from the region of the kidney to the bladder just as is usual in the passage of urinary calculi.

Dr. Wylie was again called in consultation October 31. The questions for us to decide were whether the case was one of dermoid cyst or ectopic gestation, and whether or not an operation was advisable. The history of the case, the absence of hair, teeth and nails and the great number of bones excluded the probability of a dermoid.

To do an abdominal section with the urine almost completely suppressed, with very little vitality left in the patient and with symptoms indicating an opening into the ureter and possibly into the bowel, seemed to offer no chance of recovery. Besides, a careful examination revealing no considerable tumor, we hoped a spontaneous recovery might soon take place.

Through the month of November each day's report was about the same. There was intense pain for several hours before each bone would drop into the bladder. Sometimes two or more would seem to be passing at one time. The patient could locate each one and pretty accurately predict when it would reach the bladder. The urine, always small in amount and often entirely suppressed, was taken with the catheter. As soon as the bones engaged in the urethra they were carefully fished out with the tissue forceps. On the twenty-eighth the abdomen became tympanitic and sensitive to touch, with pain particularly on the left side. The next day in several copious evacuations of the bowels there was passed liquid, blood, mucus and pieces of mucous membrane of the bowel.

The first three days of December showed marked amelioration of all symptoms. No bones were passed. Pain and tympanites decreased and the patient rested well. From the fourth to the eighth, pelvic pain and tympanites again increased, accompanied by nausea, vomiting and a slight rise in temperature. These symptoms again subsided and the remainder of the month was comparatively easy. No bones were passed. Symptoms of hypostatic congestion of the lungs that had threatened her for a month improved greatly. She slept fairly well and gained perceptibly in flesh and strength. The last three days of December and the first three days of January she passed her urine unassisted—the only time during her entire sickness.

But these hopeful signs were soon dispelled. January 4 two bones were passed accompanied by great pain. Retention of urine was followed by complete suppression; tympanites and pain increased; the cough returned; nausea and vomiting were more or less constant. Dyspnea became so marked that death

was daily expected. These symptoms continued practically the same during the entire month.

February was an easier month for my patient. On the first day I dilated the urethra expecting to find some large pieces of bone in the bladder. But in this I was disappointed, finding only a few small particles. Except being small and the walls thickened the bladder was normal. After this the bones came faster and easier. The urine was drawn with the catheter and in very small amounts. The most marked feature was obstinate constipation, the bowels moving only five times in the month, viz., the seventh, thirteenth, fifteenth, nineteenth, and twenty-eighth.

In March the bones came thicker and faster, the urethra being packed with four or five pieces at every visit, which was usually four or five times a day. The urine became more abundant. Constipation continued, the last passage for the month being on the seventeenth. A free movement was obtained on April 3. Three slight passages the twenty-eighth, the day of the operation, and a good movement the thirtieth. April was ushered in by the reappearance of menstruation, which lasted seven days. The last bone was passed on the ninth. All outward symptoms subsided one after another except obstruction of bowels. Finally peritonitis became general with pain and great tympanites; nausea and vomiting was more or less constant. The temperature range was 99 to 101.

Having despaired of the bowels moving I recommended an operation April 16. The consent of the relatives was not obtained until ten days later, when Dr. D. A. K. Steele, of Chicago, was called. Making an incision in the median line of the abdomen, loops of intestine were brought up and the fecal masses carefully broken down. The obstruction was in the large bowel and was due to fecal impaction. Remains of the ectopic gestation were sought for but practically found wanting. There were no adhesions. A small tab of healthy tissue about two inches in diameter and half an inch thick was attached to the right and back portion of the bladder.

On the right ovary was a cystic tumor about the size of a walnut and two smaller ones on the broad ligament. The ovary was tied off and removed in the usual way. The recovery was uneventful and convalescence rapid. The bowels moved freely the third day after the operation. To-day my patient is in good flesh and fair health. She is doing most of the housework for a family of six.

In conclusion, I suppose this patient conceived near the first of October, 1893; that the pregnancy was in the right Fallopian tube and that the tube ruptured in November; the embryo escaping into the broad ligament, continued to grow for perhaps six months and died, becoming a foreign body. Pressure symptoms supervened, followed by infection, ulceration and discharge of the contents of the sac into the bladder and out through the urethra. She was confined to her bed ten months. From the passage of the first bone to the last one was seven months less two days. During most of this time she suffered intense pain. No record was kept of the amount of morphin given hypodermically, but three hundred grains would be a fair estimate. The habit, if in reality there was any habit, was broken up by the sudden withdrawal of the drug the day following the operation. There was no menstrual flow from June 28, 1893, to April 1, 1894. Both before and since, the flow has been copious and comes about every three weeks.

There was total suppression of urine for ten days at two different times. In February the total amount passed was 128 ounces—an average of four and a half ounces daily. The bowels moved only five times in February and only once from March 17 to April 28, *i. e.*, once in forty-two days. The amount of bone passed was five ounces by weight and more than a thousand pieces by actual count. I have them here in an eight-ounce salt mouth bottle and they fill it to the neck. They will be passed around immediately for your inspection.

NINE YEARS OF DIPHTHERIA;

INCLUDING ONE YEAR'S EXPERIENCE WITH ANTITOXIN,
CALLING ATTENTION TO EFFECTS PRODUCED IN
DISEASES AND MORBID CONDITIONS OTHER THAN
DIPHTHERIA.

Read at the Forty-eighth Semi-Annual Meeting of the Mitchell District
Medical Society at Bloomington, Ind., Dec. 27, 1895.

BY H. T. DALGLEISH, M.D.

VEVAY, IND.

While using the serum treatment during the past year, both as a curative and as a preventive agent in a series of nearly three hundred cases, some very startling results, not so far referred to by any of the writers upon the subject of antitoxin, or at least if described by any other observer such description has not come to my notice. In these days of our entrance into a new era of medicine every new result from the use of a serum is worthy of close study and publication to the world for use. We who believe in the serum-therapy are going to be given a stubborn battle by our brother practitioners who refuse to see any good results from any serum, and who classify all such products in the same category as Koch's tuberculin; they also seem to think it a sacred duty to preach dire death and damnation against all who have the temerity to use such a remedy. The expression "refuse to see" is used advisedly, for if you ask a physician who opposes the use of antitoxin why he so opposes, the answer will usually be, that Koch's lymph was a failure and this is *just like it*, and then when further questioned as to the source of such remarkable information concerning the identity of the products, he will confess that he has neither used the remedy nor even taken the trouble to read the medical journal reports from those who have used it, but simply shuts his eyes and blindly refuses to see anything but adverse reports, and no matter how absurd or patently untruthful those reports may be, accepts every word and gloats over such an article as a personal triumph. I have brought upon my own head some such pet names as murderer and poisoner, so I say to all such brother physicians as see the dawn of the new day in which "the serum-therapy" and the principle there involved, will be the basis from which all diseases will be attacked; watch your cases closely; study them carefully and report any and all unusual or previously unnoted results, for one apparently trivial feature in a case may be, by directing attention to it, the means of saving many lives. No symptom is so unimportant but that it should be noted, no person so humble but may instruct the greatest. The results of experiments now being made in various laboratories in preparing and using a serum for almost every known disease, only partial reports of such having been made public, make it certain that in days to come medical history will have but two divisions, *the ante-serum* and *the post-*

serum periods. Serum-therapy is the logical result of the germ theory of disease causation, which is only in turn a microscopic demonstration of the doctrine of the survival of the fittest.

In October, 1886, diphtheria appeared in a mild form in Vevay and from that date to the present time there has never been six consecutive months within which I have not treated cases of the disease; the months of September, October and November have in every year produced the largest number of cases, except the past year. In December, 1894, the disease appeared in its most malignant form and has continued ever since. The disease has varied in virulence very greatly in different years; during September and October of one year I treated 123 cases without a death, the cases being all in a mild form with no tendency to invade the larynx; on the other hand during November and December of 1892 five cases treated all proved fatal, the larynx being invaded in each case, so-called membranous croup, a term, by the way, which is rapidly disappearing and the more sensible one of *laryngeal diphtheria* used in its stead, the location of the diphtheritic deposit being the only distinction. I never could understand how anyone could believe that there was any pathologic difference between diphtheria and so-called membranous croup, for in a large majority of cases the deposit begins on the tonsils and extends downward into the larynx, occasionally beginning in the larynx, and spreading upward into the pharynx. It would have been just as sensible to contend that in those cases where the deposit extended from the pharynx into the nasal cavities that the disease essentially differed in its pathologic character. Now, happily, the discovery of the Löffler-Klebs bacillus has forever settled the controversy. When I first began practice the very general treatment of diphtheria was by whisky administered in very large doses internally, and a mixture of Monsel's solution and glycerin applied locally; some advocated also the administration internally of very large doses of tinct. ferric chlorid, the very general belief being that the disease was at first local, and if the deposit was removed early in the disease the system would remain unaffected, the reverse we now know to be the fact; the deposit is the local manifestation of general toxemia, as a chancre is a local manifestation of a poisoned system. Before treating a dozen cases of the disease I noted that however often the deposit was removed so long as fever and other systemic symptoms were present the deposit rapidly returned, but upon the subsidence of the fever and disappearance of other symptoms of infection, the deposit, or false membrane exfoliated without any local treatment. And from that time to the present I have never used any local treatment whatever with the object of removing the false membrane, but solely with the view of rendering or keeping the deposit aseptic. My treatment until the discovery of antitoxin has been the tincture of iodine in dilute alcohol. For an adult one drop of tinct. iodine to thirty drops of alcohol with enough water added to make a tablespoonful swallowed slowly every hour, and the dose of both iodine and alcohol diminished in proportion to the age of the patient. In all but the malignant type of the disease it acts like magic; its great advantage over all other remedies being that it will be retained when all other remedies as well as food are rejected by the stomach.

Since Jan. 1, 1895, I have treated fifty-seven cases of diphtheria varying from the most malignant to moderately severe cases, none having been mild. Antitoxin was used in all cases; there were two deaths with fifty-five recoveries, a mortality of less than 4 per cent. During the same time I have made over two hundred inoculations as a preventive measure; not one of those inoculated have taken the disease. Quite a large number of those inoculated had been exposed to malignant cases, and in several instances where a case occurred and the whole family had been exposed, but some members having declined to be inoculated, some of those so declining contracted the disease, while all of those inoculated escaped. Nine persons were inoculated after prodromal symptoms were present and well marked, and in all such cases all of these symptoms had entirely disappeared within thirty-six hours. When inoculating as a preventive measure I have uniformly given 200 antitoxin units (Behring) and repeated the same at the end of three months. As a curative measure, when the disease was well established, the dose has varied greatly, being governed by the duration, age of the patient and by the severity of case as indicated by the symptoms, as follows: Where the membrane was still confined to the tonsils and the temperature not exceeding 102 degrees F. I have uniformly given 400 units, watched results and if at the end of twenty-four hours there was an improvement as indicated by subsidence of fever and no extension of membrane, given 200 additional units, and in such cases uniformly nothing more was required. But if at the end of twenty-four hours there was no improvement, the case remaining unchanged, 400 additional units was given and repeated each twenty-four hours until cured. If after first giving the 400 in such cases, at the end of twelve hours, when I always make my second visit, I found the symptoms worse I gave from 600 to 1,500 units additional according to the apparent severity, I then visit my patient every six hours, administering 200 units at each visit until improvement is manifest.

If on first seeing my patient the false membrane has invaded either the larynx or post-nares, or the terrible stench indicates that the streptococci have been absorbed and that in addition to the toxic effect of the bacilli diphtheriæ, I have a case of septicæmia to fight, I administer from 1,500 to 4,000 units at once and then give from 200 to 1,000 additional every six hours until improvement, and I have never yet treated a single case that there was not improvement. The two cases in which there was a fatal result both died after my visits had ceased and they apparently were safely convalescent. One, who, contrary to my instructions, had been allowed to go out in the yard and spend the afternoon reviewing a circus parade, died that night from heart failure, not paralysis. The other died from heart clot. Both had been of the most malignant type, having in addition to involvement of both nares and larynx the additional feature of septicæmia. In both case the false membrane had readily disappeared from all points, after which I had a long, stubborn battle with the septicæmia (due to the streptococci) which left them extremely enemic. Both cases were far advanced in the disease before treatment was begun, the glands being greatly swollen when first seen (the cervical lymphatic glands). One recovery was a case primarily of laryngeal diphtheria, the membrane extending on the third day to the tonsils.

Summing up, my conclusions are as follows: In average cases when seen early, give from 400 to 600 units and repeat at intervals of from six to twenty-four hours. In malignant septic cases or where the larynx is involved, give from 1,500 to 4,500 at the initial dose and repeat with from 200 to 600 every six hours and give stimulants. When the nares are involved use an antiseptic wash every two to four hours.

So far as the membrane or diphtheritic deposit is concerned the greatest danger from it is the streptococci and the staphylococci contained in the superficial layers and which if absorbed add to your case, which is primarily a poisoning of the blood with a toxin generated by the Löffler-Klebs bacilli, either from their life activity or as a product of their decomposition after death. The additional element of ordinary septicæmia, the danger of absorption, is much greater from the larynx than from the pharynx, and greatest of all from the nasal cavities, they being so difficult to cleanse, and the danger of absorption from the nares continues for weeks if the antiseptic douche is not continued for some days after the membrane has disappeared. Paralysis after diphtheria is nearly always due to pus absorption, hence the necessity for keeping the superficial layers of the deposit which contain the pyogenic bacteria aseptic. Paralysis after cases treated with antitoxin is slight and rare. The bacilli diphtheriæ are burrowed in the mucous membrane and the diphtheritic deposit or false membrane is thrown up as the crawfish chimney is thrown up by the crustacean as he burrows in the ground. When the underlying bacteria die the deposit exfoliates. The exhaustion following even mild cases of diphtheria not treated with serum is entirely wanting after the serum treatment, most patients expressing themselves as being *stronger and more vigorous after recovery than before contracting the disease*. In addition to the preceding remarkable fact, the following additional surprising results were noted as a consequence of serum inoculations: Some were made as a preventive measure and part were purely experimental, being made by me with the consent of parents. A child 13 months old was weak and undeveloped, having been bottle-fed and had never taken any form of nourishment without also taking a digestive ferment with the food or after. It had also suffered from birth almost constantly with diarrhea and vomiting. This child along with the other members of the family was inoculated with serum as a preventive; since twenty-four hours after the inoculation it has never taken a dose of medicine, has not had diarrhea and rapidly gained in weight. The father called my attention to the fact about a month after the administration of the serum, and while on my way home from his house I met a lady who is the mother of a child with the same history, and which had been inoculated a few days before the first case; the mother called my attention to the child and stated that the results had been identical with the other. Since then I have inoculated a considerable number of children with the object of improving their nutrition and digestion and the results have been magic in every case. A tuberculous patient has been greatly benefited since being inoculated as a preventive of diphtheria. Two paralytics treated at their own request by serum injections have improved in weight and strength in paralyzed muscles. Two cases of melancholia treated by me for want of some

better thing to do in their cases, have shown improvement; but these as well as the former two are not trustworthy, as the results may be purely from a psychic cause.

The most satisfactory results of all in this class has been in two little boys born of tuberculous parents, and since birth have been subject to ulceration and pus formation in various portions of their bodies, so-called scrofulous children. One is six, the other is eleven years of age; both were thin, pale and anemic; both have grown fleshy and much stronger, the color of the skin entirely different; in short, an entire change in their nutrition.

BACTERIOLOGY.

Read in the Section on Dental and Oral Surgery, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY S. A. HOPKINS, M.D.

BOSTON.

(Concluded from page 275.)

In connection with diphtheria, certain important work has been done at the Harvard Bacteriologic Laboratory, and as I myself have been engaged in that work, it might interest you if I describe in brief what has been accomplished. The Board of Health of the City of Boston has turned over to Dr. Ernst and his associates the work of making examinations in suspected cases of diphtheria, and of preparing the antitoxin for its treatment. The following method has been adopted and has proved eminently successful in examinations for this disease:

Boxes are provided containing two tubes of culture media. Usually blood serum or hydrocele fluid is used, agar-agar if they are not to be obtained. These boxes also contain a platinum wire, and they are to be procured at the college or from drug stores which are scattered throughout the city. When a suspected case presents itself the physician procures one of these boxes and proceeds to the house of the patient. After sterilizing the wire, he places it along the edge of or into the deeper portion of the false membrane of the throat. He then draws it lightly over the surface of the culture media in the tube, and the box is sent to the laboratory. There the culture is allowed to grow over night in an incubator kept at the temperature of the body. The method of its growth is noted, and cover-glass preparations are made and submitted to the microscope. In twenty-four hours or even less time the physician receives his report and is able to make a diagnosis. Occasionally a second or even a third culture may be necessary, as the fact of the bacillus not appearing in the culture is negative evidence only, and may be due to a technical mistake or lack of care in inoculating the culture media. After the patient has recovered, or after apparent recovery, cultures should still be made at frequent intervals, and not until two or more negative cultures have been obtained should the patient be allowed to come in contact with others. Frequently the bacillus appears several weeks after apparent recovery. It is expected that the antitoxin treatment will be introduced to go hand in hand with this work of the board of health, and to that end both the State Board and the Board of Health of the City of Boston have made arrangements for the production of antitoxin from horses.

The preparation of antitoxin is exceedingly interesting. It is known that certain animals can be

immunized against certain diseases, and upon this assumption rests the foundation of serum-therapy. This immunity may be produced in several ways; one is by inoculation of a different disease of a milder type, as in the familiar example of vaccination; another is in attempted cultures of the same disease, producing the disease in a mild form; still another is by inoculating with the poisonous products resulting from the growth of the bacteria, the tuberculin, which is the toxin of tuberculosis; a fourth is by an antitoxin produced in the system as a result of the action of a toxin. When such a poison or toxin is inoculated into susceptible animals, a peculiar cell action, about which our knowledge is limited, takes place, which results in the production of an antidote for that poison.

In diphtheria, the Klebs-Löffler bacillus is found in the throat; we do not expect to find it in the blood. Its presence then in the throat does not necessarily produce death. It does, however produce a poison, a toxin which, entering into the blood, may result in death if the cell action is not active enough to produce something in the nature of an antitoxin which will overcome the effects of the poison. I do not want to convey the impression that a simple chemic antidote for poison is produced in the blood, for it is probable that this is not the case, but that certain changes in the tissue cells, possibly some leucocyte action, enters into the process as well; but for the sake of simplicity we speak of it in this way as an antidote to the poison. If, therefore, the cellular action is sufficient, an antidote is produced which overcomes the poison, and the patient recovers. It is for the purpose of supplying this antidote artificially that we prepare the antitoxin from horses. Horses are selected because they are easily immunized and the immunity can be carried to a very high degree. They are usually healthy animals, are easily handled, and a large quantity of blood can be taken from them without serious injury, which blood contains a large proportion of serum. The steps of the process are somewhat as follows:

We first make a virulent culture from some severe case of diphtheria. It is, however, a fact well known in the laboratory that the most virulent cultures do not always come from the severest cases. We have to determine the degree of virulence by experiments. This is done by inoculating a small quantity of bouillon, and allowing the bacillus to develop in this for twenty-four or forty-eight hours. The bouillon is the ordinary beef bouillon with 2 per cent. of peptone and a small quantity of salts added. Microscopic tests are then made to determine if the culture is pure, and if it is found not to be contaminated, experimental inoculations are now begun upon guineapigs, and if it is found to kill in forty-eight hours a guineapig of 500 grams with a dose of .5 c.c. the culture is assumed to be virulent. An autopsy, however, is made to confirm, and if it is then ascertained that the guineapig died from this cause, we feel sure that the culture is virulent. The cultures increase in virulence as they pass through the animals.

The next step is the inoculation of large quantities of bouillon in flasks of appropriate size with this virulent culture, and these flasks are placed in an incubator kept at the temperature of the body, and the bacteria are allowed to grow and develop for a month or six weeks. By passing a current of filtered air over the bouillon in which the organ-

isms are growing, the process may be shortened, and in three weeks, if everything has been favorable, we may have a toxin which is of sufficient strength for inoculation. The bouillon is taken from the flasks and carefully tested to see if there are any organisms except the Klebs-Löffler, and if no contamination is shown, it is filtered through a porcelain filter, a modification of the Chamberland candle, suggested by the brilliant Japanese scientist Kitasato, and it is then ready for the inoculation of horses. Before inoculation, however, its strength is tested on guinea-pigs. A normal toxin is one that will kill a guinea-pig of 500 grams by a dose of .1 c.c. in forty-eight hours or less. Toxin of this strength requires great care in handling it, and in the first injections into the horses a small percentage of Gram's iodine solution is usually added to reduce its irritant properties. Injections having once been begun are carried on at intervals of a few days, gradually increasing the doses, until at the end of two months an injection of 50 c.c. of a normal toxin can be made without the horse suffering any ill effects beyond a certain febrile reaction. This failure to react under increasing doses indicates that immunity is becoming complete, and at the end of a period of not less than eighty days, usually a much longer period is required, if the injections have been successful, there should be a very considerable amount of immunity, and at this time the jugular vein may be opened and a certain quantity of blood taken from the horse.

From the serum of the blood thus taken the antitoxin is prepared, and its preventive and antitoxin power is determined upon guinea-pigs by finding what percentage of antitoxin will be required to overcome a fatal dose of the normal toxin. For practical use this power should not be less than 1-50,000 and if 1-100,000 can be obtained, so much the better; that is to say, 1-100,000 of antitoxin in a guinea-pig should prevent fatal results from the inoculation of an amount of toxin which would ordinarily kill in forty-eight hours, that is 1-10 c.c. of toxin will kill 500 grams of guinea-pig; 1 c.c. or ten times as much will kill 5,000 grams in the same time. Now if 1-10 c.c. of antitoxin will render inert 1 c.c. of toxin it is an antitoxin of the strength of 1-50,000; if it is double that strength it is an antitoxin of 1-100,000. Do I make myself understood? It is possible to produce it even stronger.

To indicate what has already been done by this method of treatment, I would refer you to the reports of the Hospital des Enfants Malades in Paris, where the reduction of mortality in the diphtheria wards has been from 60 per cent. to 24 per cent. Later advices from Paris would seem to show a still greater improvement. At the City Hospital in Boston the treatment by antitoxin was begun December 9, and the period from which I take the following figures was from that date, December 9, to about January 22. At that time, as you know, the antitoxin was very hard to get. It was not to be obtained in large quantities, and was very expensive for hospital work; moreover the antitoxin power of the serum was not as great as it should have been. Manufacturers who had been tempted by the high prices had put material on the market before it was ready for use.

Notwithstanding these drawbacks, of sixty-nine cases treated only eleven died. This is a percentage of about sixteen, and during the corresponding period of the previous year the death rate was 52 per cent.,

and that is the usual hospital death rate from diphtheria. It should also be remembered that only the severe cases were treated by antitoxin on account of the expense. Of the eleven patients that died the average length of time which had elapsed since the beginning of the disease until they were treated was 5.2 days, so long a period that in some cases the patients were almost moribund when they entered the hospital. Some of the cases were complicated by other diseases, one patient dying with scarlet fever four weeks after apparent recovery from diphtheria, one dying from pneumonia, and so on. Without elaborating this subject, if these results are to be corroborated by further and wider experiments, it would seem that in antitoxin we have a remedy that in uncomplicated cases which are treated early and in sufficient doses will prove almost unfailing. But more important than this is the fact that through this agency we seem destined to acquire a new system of therapeutics. The door is open for further investigation, and it is impossible to predict how many diseases may answer to treatment on similar lines.

If I have perchance exhausted your patience in thus enumerating some of the results accomplished by bacteriology, I have done so under the impression that to no class of specialists is the subject fraught with greater interest than to dentists. The mouth is teeming with bacteria and is indeed a hot-bed perfectly adapted for their production and development. Not one of the necessary conditions is wanting. We find the exact temperature best suited to the growth of most varieties, we have the moist condition, free access of oxygen, and we have in the broken down epithelial cells and in the particles of food, which even the greatest care can not remove, a perfect soil for their development. Investigations in this field teem with the possibilities of brilliant discoveries that may serve to revolutionize our whole practice, and render to our suffering patients inestimable services. The field is one that is almost uncultivated, and scientific work in this direction can not fail in producing wonderful results.

Even the brilliant work of Miller, Vingal, Black and others has been but a beginning, an important beginning I grant, which will make the work of studying these forms easier for you and for others who may attempt their study, and we shall have daily occasion to be grateful to these pioneers for the difficult work which they have performed. The tendency has been, however, to cover too much ground, and the incompleteness of the work is best described in Miller's own words: "I myself have made the mistake, which I think others have made, of attempting the impracticable task of examining all the species which I have isolated instead of concentrating my attention upon individual cases and studying them thoroughly." This certainly has been the tendency, and in but few cases has the work been carried out to its ultimate completion. To illustrate my meaning better, certain chromogenic or color-producing forms probably account for certain discolorations of the healthy teeth and for the pigmentation of carious dentine, but in the present state of our knowledge, we can go little further than the mere statement of the proposition, although it is a subject of vital interest to us. Work upon the fermentative power of certain mouth bacteria seems to point to the conclusion that some of the digestive processes are dependent upon the presence

of bacteria. Yet we are still in the dark as to what forms perform these important functions.

In connection with diseased pulps, we have a great deal to learn. It is no reflection on our intelligence to say that probably not two men in ten would use exactly the same methods in treating the same conditions presented by a diseased pulp. I am convinced that through applied bacteriology we shall be able to differentiate between the various conditions, and to treat them with uniform success. One of these conditions has recently occupied my attention, and I hope in time to offer some definite results. It sometimes happens that a dead tooth which has given no trouble for years sets up an active inflammation a short time after it is opened. This has been accounted for by saying that the entrance of air laden with bacteria produces the trouble. Miller demonstrates that a liter of air contains such a small number of bacteria that this explanation is unsatisfactory, and he disposes of the matter by asserting that it must be due to the carelessness of the operator in forcing putrid matter through the foramen apicale or in introducing infection by means of unclean instruments. I think these charges may be unfair, and I think the explanation will be found in the fact that certain facultative anaerobic bacteria become aerobic and develop rapidly under the new conditions which the increase of oxygen furnishes. Spore formation, I am inclined to think, may also account for certain conditions which now seem very puzzling. But this is a digression. In the greater subject of caries of the teeth such careful bacteriologic work has been done that we have no longer any doubt as to the causes of dental caries. Black in his "American System of Dentistry," Vol. i, says; "That herein lies the true explanation of the etiology of dental caries there is no longer a reasonable doubt." My own opinion is that he has not put the matter too strongly, and that we but waste time in pursuing other theories. Much remains to be done, however, in the way of differentiation and classification of the various phenomena of this disease, and it presents an inviting field for the investigator.

Miller describes the process of caries as a chemico-parasitic one, and divides it into two stages, the first being the destruction of the enamel by acids. The destruction of the enamel is chiefly due to lactic acid, which we have learned is brought about by the action of bacteria, several forms being probably engaged in the work, and saccharin and starchy foods being the important media for their development.

The second stage, the destruction of the dentine, is now pretty generally accepted as being due to bacteria, but to what specific forms these changes are due is still a matter of conjecture. Our present knowledge seems to point to the fact that the so-called *leptothrix buccalis* is not to be considered as one of these forms. Miller calls particular attention to five different kinds, four of which are cocci forms, and one a bacillus or spirillum. All have the general property of fermenting carbo-hydrates and of producing lactic acid. Galippe and Vignal have isolated six varieties, five of which are bacilli and the sixth a large coccus.

A puzzling discrepancy you will at once see exists between the results of these brilliant workers. In the October number of the *Centralblatt*, Dr. Carl Jung gives the results of important work that he has done in the same direction. He has isolated ten dif-

ferent varieties, eight of which are rod-shaped forms and the other two cocci. He has made use of a variety of culture media, and has advanced our knowledge of this subject a little further in the unknown field, but he concludes by saying that although one or another kind of bacteria may take part in a particular measure in the various forms under which caries appears, it must be proved by more advanced research. To this I would add that further researches must be made along the lines which Koch has laid down as applying to all pathogenic forms, and which I repeat: 1. The organism must be constantly present. 2. Pure cultures must be made. 3. These must be able to reproduce the disease. The first two conditions have been in a measure fulfilled in caries, although much still remains to be done in the way of devising new culture media. To fulfill the third condition, a most interesting field for experimentation is opened to us. Before we can determine the specific factors in caries, we must first fulfill the third of Koch's laws and produce the disease by pure cultures of the bacteria that we find to be constantly present. Such work presents obstacles but no insurmountable barriers, and it can be carried out upon lines somewhat as follows: A certain number of freshly extracted teeth must be obtained and covered with paraffine, wax, or other suitable material, leaving exposed only such portion as we wish to have acted upon. One of these, previously sterilized, is placed in a mixture of bread and saliva in a test tube, plugged with cotton and carefully sterilized. Into this is then introduced a pure culture of one of the organisms, and the culture is allowed to grow at the temperature of the body for several months. The experiment is varied by selecting teeth of all kinds, by boring into some and exposing different portions, by varying the kind of organism used, and by mixing the cultures in some of the tubes. This work has never yet been carried out to its ultimate completion, but the work is now in progress, and I refer to it in order that others may be encouraged to take it up. From what I have seen, I believe that when this Association holds its next annual meeting we shall know the specific work performed by the various organisms that take part in the destruction of the human teeth, and shall be able to differentiate between one form of caries and another. When this is accomplished, we shall be far on the road leading to the discovery of more suitable prophylactic and curative measures than we now possess.

I have taken so much of your time already that I will not stop to point out the bacteriologic aspect of pyorrhea alveolaris and other baffling diseases of the mouth, nor can I more than hint at the possibility of the saliva becoming pathogenic under certain conditions, but all these are burning questions which we have got to solve if we would elevate the profession and make it what it should be, an important branch of medicine.

Throughout this paper I have purposely avoided any reference to the treatment of diseased conditions and to practical operations, for as I said in the beginning, no class of men are more alive to the practical affairs of their profession than the dentists of America. It has been my object rather to stimulate your interest in bacteriologic work, and perchance to induce others to make further progress in the direction that I have pointed out. If I shall have succeeded in this, I shall feel that my labor has not been in vain.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.

W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, FEBRUARY 15, 1896.

EUGENE FIELD.

In an eloquent tribute to the memory of the late EUGENE FIELD, the *Medical Mirror* of St Louis, says:

EUGENE FIELD had promised to furnish the Editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, a special poem descriptive of the doctor's life. It was the intention to have had it liberally illustrated and FIELD was planning in his mind the play of the lines. Indeed he had expressed great enthusiasm in the work, feeling that it was an opportunity for him to delineate the doctor as he had met him and as he knew him an ever faithful and devoted friend of his patients. By association and general equipment he was in good form to have presented a product which would have marked an epoch for the medical profession in a literary way, and we venture the opinion that the subject was one so filled with interest and general attractiveness that the work which was being planned so enthusiastically would have been the literary cap-sheaf of his life, one arousing the interest and the appreciation of the entire medical world. So that his sudden and untimely death was more than ever a calamity to the lovers of true sentiment.

The plan as outlined by MR. FIELD was to take for his type some middle-aged practitioner engaged in family practice, and follow him in his rounds on a Christmas morning. The child patient surrounded with every luxury; the child in less favored circumstances, and the poor sick child amid its pathetic surroundings, were each to have their say to the good doctor as he traveled on his errand of mercy from house to house, and that EUGENE FIELD, better than any poet then living, could have voiced the tender Christmas prattlings of the infant clientelage, every one who has read the productions of the child's poet must admit. And so the loss of EUGENE FIELD

was a direct and personal loss to the medical profession.

The article as outlined above, was intended to appear in the Christmas number of this JOURNAL, and to several friends he mentioned thoughts and expressions that he intended to have his sick children use, but man proposes, God disposes.

TREATMENT FOR PHTHISIS PULMONALIS.

In a very interesting article,¹ DR. CYRUS EDSON, of New York, states that during a study of phenol, made in the early part of 1895, he was very much struck by the observations of STADLER, MERCK, BRIEGER, SALKOWSKI and others, to the effect that phenol could be found in the urine of man the horse, and the cow, and that during health it is a normal constituent of the urine, and during disease the per cent. is enormously increased. He is of opinion that the high temperature of fever may arise from the poisoning of the nerve-centers by such products, and that if this be true, the increased secretion of phenol by the system during disease is an evidence of the *vis medicatrix naturæ*. This led to the proposition: "If nature herself provides phenol during disease, then it can not be possible she will not tolerate the administration of the agent in effective dosage," and yet the fact that effective dosage was believed to cause poisonous symptoms, seemed to be against its use. It is apparent that phenol being the only known antiseptic agent, except cresol, of which the amount in the system is increased during disease, it would be best to select that for experimental purposes, and the problem of DR. EDSON is to find the form of solution of phenol which nature would tolerate. It is to be remembered that creosote is not phenol, but has it as one of its constituents, and that the two substances are therefore not identical. In the opinion of DR. EDSON, the success of the creosote treatment depends mainly on the presence of the phenol. After a long line of experimental work in the laboratory, he has produced a fluid which he uses in his formulated treatment of phthisis, which DR. HENRY A. MOTT speaks of as "aseptolin," and which term DR. EDSON adopts. The fluid is a chemically pure solution of pilocarpin-phenyl-hydroxid. He added the pilocarpin for two reasons: First, "to induce leucocytosis: second, to stimulate glandular activity." It also accomplishes a third purpose, for it is an expectorant and stimulant of secretion of very considerable power. It causes a certain increase in the amount of water separated from the blood in the lung cells. This is shown by the fact that there is an increase of watery vapor carried off by the breath of a person taking it. After a short study of pilocarpin, he further says: "From what has been said, it will be apparent to all chemists that the fluid is a hydrophenol, containing a definite

¹ Medical Record, Feb. 8, 1896.

amount of the new pilocarpin compound. The solution prepared in my laboratory is a colorless fluid, strongly refracting light, having the characteristic odor and taste of phenol. Injected under the skin, it causes a sharp, burning pain, not so severe as that following an injection of bichlorid of mercury in solution.

"In the great majority of cases the injection is not followed by any local irritation whatever. . . . Though I have given over one thousand injections, and some of them very large ones, viz: single injections of 350 minims each, I have not seen a single abscess resulting therefrom, and nodulation in only two cases: one of these was on my own person, following an injection of 250 minims for experimental purposes. No reaction, such as follows the administration of tuberculin, is observed after the injection of properly prepared pilocarpin-phenyl-hydroxid solution, nor is there any visible physiologic action following an injection of 250 minims, given to a man weighing 150 pounds, except that the urine passed subsequently reacted strongly to tests made to ascertain the presence of phenol, and traces of phenol were noted in the condensed vapor of the breath, and in the contents of the stomach drawn off through the esophageal tube within three hours of injection." He recommends a dose of fifty to seventy minims daily to commence with, given in the abdominal parietes in a single injection. This dose should be increased ten minims daily, until 100 or 120 minims is reached. With these injections, he injects daily, or in some cases every other day, according to the severity of the case. He gives inhalations delivered from a spray. The most efficient of these sprays he has found in a 10 per cent. solution of iodoform in ether. The object of the spray, he says, "is to assist in clearing the larynx and bronchi of infective material contained in their secretions." Where this spray is not tolerated by patients, he uses a carbolic acid spray for a few times, after which the iodoform and ether can be used in most cases. Not only does he regard this as a useful treatment in phthisis, but in malaria as well. It will be noticed that Dr. Edson does not herald this as a "cure," but simply submits this treatment to the profession, and we are inclined to believe that the startling announcements in the papers, like the notice of a bill agent, with which this new treatment was heralded, was due rather to the enterprise of our distinguished contemporary, than to any desire on the part of Dr. Edson to place himself in a false light before the profession. He has experimented sufficiently to make it clear that he has produced a useful method. Whether or not it may reach the dignity of a specific, he very properly leaves the profession to decide after a careful trial of the remedy.

We will reproduce the article in full next week.

THE ITALIAN SCHOOL OF CRIMINAL ANTHROPOLOGY.

It is so common for men to dislike what is or seems absolutely new that we are not surprised that the Italian school of criminal anthropology—the so-called positivist school—should have so many enemies. For the teaching is so novel, so sweeping, so unpleasantly tinctured with fatalism, that it is naturally very obnoxious to the optimists of religion and science. But we imagine that much that is felt by excellent men on this subject is prejudice (if the word be not too severe) springing from a superficial knowledge of the works of the Italians themselves and their coadjutors in France and Germany. It will doubtless surprise those who have no other notion of this science than what an acquaintance with the least discreet of authors¹ affords, to be told that among those who have studied it with conviction are not only many of the most elegant of contemporary writers, but also many of the most learned and profound.² It is, therefore, amusing to hear that the investigations of the Italian school are mere exhibitions of morbid curiosity, or as Dr. SPITZKA says: the "pseudo-anthropology is dead just about three years." A competent critic has pronounced a very different opinion, *apropos* of the recent publication of the fifth edition of PROF. LOMBROSO's chief work "*L'Uomo Delinquente*." "In fine, whatever we may think of the value of all these details, all these documents taken by themselves, the least that can be said of them as a whole they confirm beyond any possible doubt the thesis of M. LOMBROSO. Everybody, or nearly everybody, to-day is agreed on this point—that the criminal is an abnormal individual, malformed mentally and physically—for to every mental anomaly should correspond a physical *par dégénérescence héréditaire ou par déchéance acquise*."³ Even Dr. BAER, the most prominent and the least fair-minded opponent of PROF. LOMBROSO, admits that the criminal, *i. e.*, the habitual offender "who is apparently born such" bears "many signs of physical and mental imperfection," but these signs he goes on to say are neither singly nor as a whole so constant and essential as to make the criminal a type distinct from the rest of his nationality. We resist the temptation to examine the logical structure of this sentence. The habitual and born criminals are not necessarily identical; and it is usual for anthropologists to draw a distinction of more or less lucidity between them. But we pass to another point of view. It is well known that many anthropologists have attempted to show that in the case of

¹ Dr. Max Nordau's "Degeneration."

² See Taine's letter to Prof. Lombroso, *Archiv. di Psichiatria*, Fasc. v, 1887; Darwin: *The Emotions in Man and Animals*; Delzett-Newwin: *Ueber Sittliche Dispositionen*, Gray, 1892 (in this work is an excellent criticism on the older investigations of Galton and De Candolle); Spencer: *Sociology*; Du Camp: *Rev. des Deux Mondes*, 1869; Gautier: *Le Monde des Prisons*, in *Archives d'Anthropologie Crim.*, 1888; "Gyp," (an admirable study of the so-called Decadents); Dostiewsky: *Le maison des morts*, etc. by Garofolo, *Criminologia*, p. 79; *Quarterly Review*, October, 1891.

³ *Rev. Scientifique*, October, 1895.

born criminals the phenomena of the criminal instinct are identical with the obliquities of moral insanity. A fierce outburst of polemic rage followed the publication of this doctrine. Those who disbelieved in the existence of moral insanity, and those who were averse to reading PROF. LOMBROSO's works in the original were the most *embêtés*. It is simply necessary in this and in other cases where controversy grows wicked to read the passage that has provoked all the sound and fury. "It was objected with reason against the fusion, I attempted to prove in the first volume, of the born criminal with the *pazzi morali*, that the number of these is too small. It is certainly true; but if the born criminal and *fou moral* are the same it is inevitable that not many should be found in asylums. Nor is it possible to draw a comparison between the two; since identical things are more naturally summarized than compared. But there is a point of contact between them much easier to define, and incomparably more important, in a vaster field, in epilepsy, which reunites and founds together the one and the other group into the same grand family."⁴

If the reader will refer to the fifth Italian edition of "L'Uomo Delinquente" or to the second French edition, he will find an extraordinary amount of documentary, biologic and statistical evidence to support these views. The number of criminals studied reaches nearly six thousand, as against 968 examined by DR. BAER. The reader will find, too, if he desires in good faith to make the acquaintance of an ingenious work, a learning, eloquence, fecundity, humanity, the great merits of which we should not "haggle about," as the writer in the *Revue Scientifique* says. A perusal of this work, too, will dispel a common error, namely, that an excessive value is placed upon such phenomena as the *signes de dégénérescence*. The doctrine of degeneration, says KURELLA,⁵ "is imperatively in need of revision." On this point practically all observers, LOMBROSO⁶ among them, are agreed. It is significant, however, that the *signes de dégénérescence* are exceedingly common in epileptics,⁷ so common, indeed, as to be fairly constant. But as in criminals they are much less constant an appearance, it is impossible by means of them alone to constitute a type. Their importance it is impossible to deny.⁸ An authority competent as DR. MOEBIUS,⁹ makes the diagnosis of neuropathy in the appearance of even one sign, as, for instance, the Morelian ear; and any anthropologist may easily verify the observation for himself that such an imperfection is never as LOMBROSO truly says, disassociated from "*profondi quasi morali*;" or at least from distinct oddities of disposition.

It is not to be forgotten that the industry of the Italians has revealed to us a large number of signs which materially assist to establish a type, that we may call physiognomic¹⁰ and certain traits, or "*penchants au crime*," that DR. MARRO has excellently described in his treatise, "*I Caratteri dei Delinquenti*." We extract from the preface of this work a passage which we think ought to be a red eye-opener for the blind optimists who see in criminal anthropology no balance, no moderation nor judgment, but only a desire to make the venture of Icarus. The following passage shows anything but the sweeping indiscretions with which the positive school is charged: "I have included the inclination to excesses (in Baccho) among the characteristics of criminals, who are more addicted to them than normal people. My own observations on this subject are in complete accord with those of other students, so that there can be no doubt about their value. With all that, I do not see in inebriety a disposition inseparable from crime, nor do I in the least attribute to alcohol a power absolutely compelling evil."

This passage is quite admirable as an example of the ability to see two sides of a question. And such moderate views abound in the works of LOMBROSO and his pupils, as any accurate knowledge of their writings will show. It is a proof of how uncommon the power to judge coolly is even among scientific men, that MARRO's work, thoroughly judicious in tone throughout, has not been unattacked by partial critics. Contrast the above from MARRO with the following: "The criminal has absolutely no especial specific (sic) formation,"¹¹ and "crime, on the whole, is only a relative conception; it exists only in relation to place and time."¹² Again; "whoever," says DR. BAER, "knows extensively the criminal classes, their characteristics, their appetites and aberrations, will acknowledge that such traits and uglinesses as LOMBROSO ascribes to them in such prodigious amount (sic) are not common, perhaps not commoner than among the better classes, the non-criminal portion of the population." The truth is that in opposition to this assertion we have an overwhelming amount of evidence not only from gifted observers like GAUTIER, DICKENS, DOSTOIEVSKY, MOREAU, but from trained observers like MAUDSLEY, CLOUSTON, KURELLA, GAROFALO, CASPER, KRAFFT-EBING, and even NICOLSON¹³—no believer in "criminalists." Indeed, such is the weight of authority on this point that GAROFALO is not putting it too strongly when he says: "We consider so much as solidly established that, as regards the shape and proportion of the head, the criminal is monstrous and anomalous

¹⁰ For an admirable use of these signs, see Casper. *Vierteljahrsschrift f. gen. Med.*, 1854.

¹¹ Baer: *Der Verbrecher*, p. 334.

¹² Féré, cit., Baer. Dr. Spitzka says that Baer's critique has remained unchallenged. The truth is "*Der Verbrecher*" is nothing but a tissue of dogmatic assertions. It has remained unchallenged because as Prof. Lombroso says, "*Si combatte coll' armi non coll' ombra!*"

in a larger number of cases than the normal man; and the greater criminals, the assassins, much oftener than the lesser. . . . Each of the three great varieties of evil-doers, the murderers, homicides and thieves has an especial physiognomy, with well-known traits and easily recognizable."¹⁴ He remarks that he was able to distinguish the murderers from the thieves in a prison, by the peculiar cold, filmy, immovable glance that is characteristic of habitual homicides,¹⁵ whereas the thieves have a mobile, elusive look.¹⁶

All this may seem fanciful and absurd to many readers. We can understand it, for the power of observing profoundly is not given to all men, and it is, perhaps, fortunately so. But in such studies as these it is absolutely essential to observe calmly and sharply, to be on one's guard against the *idola specus*, that spurious blindness of specialists, who see in everything some reference to their pet subject. We assure our readers, however, that criminal anthropology is a study that will repay any one who approaches it in a liberal spirit. It is not of such recent growth as some seem to imagine, but imbibed life from the earliest springs of psychiatry.¹⁷ It can not be called "dead," it is very much alive, as the writer in the *Revue Scientifique* could show, a writer who represents much more nearly than Dr. BAER the opinions of modern Europe.

THE ROENTGEN RAYS.

The general interest in the recent discovery of PROF. ROENTGEN, the details of which now fill the daily press and which were at first received with incredulity by the public as probably a scientific hoax, seems to call for some notice in the JOURNAL. Its medical or surgical possibilities which are already the subject of experiments in this country and Europe make this mention the more timely and appropriate in a purely medical publication.

In regard to the scientific question as to whether the results obtained by experimenters are due to the previously recognized cathode rays or to a new form of radiation as PROF. ROENTGEN suggests we can of course express no opinion; it is a matter to be decided by physicists. The fact that we have, however, a force, for that is what it may be called, that will act on the sensitive chemicals of the photographic plate through flesh, cartilage, skin, and other tissues of the animal body, is enough to be fertile of practical suggestions to any thinking physician or surgeon. The further fact that these rays go directly through prisms and lenses without modification or change of course, adds to their possibilities in a medical point

of view; it insures the accuracy of the image from distortion by refractive power of the different solids and fluids of the body. The further fact that in a general way only the density of the medium penetrated seems to affect them is suggestive of practical medical and surgical possibilities, it hints at future valuable physiologic revelations as well as diagnostic aids. It is only a hint, however, and whether it is to be ever realized to any extent is perhaps open to serious question. As regards its therapeutic possibilities which have already become the plaything of the popular imagination, they may be left to future investigation: they are not in a stage as yet for medical opinions to pass on the question of even their existence. There will doubtless be an extensive advertisement of cathode ray baths, X ray treatments, etc., but it is to be hoped that any active exploitations of these will, until the matter is more elucidated by accurate scientific researches, be confined to the irregulars who have no standing in the regular medical profession.

The real utility of the discovery has so far been demonstrated to a limited extent in the field of surgery. A few accounts have appeared in the lay press of needles, bullets, etc., having been detected lodged in the tissues, and some light has been thrown on pathologic diagnosis in one or two cases. In France M. LANNELONGUE believes he has been able to show by this method that in a femur affected with osteomyelitis the destruction of bone progresses from the center to the periphery rather than in the opposite direction as had been previously held. When it is considered that the discovery is as yet only a few weeks old, and that students all over the civilized world are laboring to investigate it and to perfect the methods of its application, it may not be unreasonable to hope for much more important results in the near or remote future. At present, however, the limitations of the methods are too great and the medical nature of the discovery is, as yet, a largely unknown quantity. Its surgical utility in certain ways has probably been sufficiently indicated by what has been already done, but enthusiasm as to its future should be tempered by a scientific spirit of moderation that proves all things before building its faith upon them.

THE COMPOSITION OF EXPIRED AIR AND ITS EFFECTS UPON ANIMAL LIFE.

In May, 1893, a grant was made from the Hodgkins Fund of the Smithsonian Institute to Drs. JOHN S. BILLINGS and S. WEIR MITCHELL, "for the purpose of conducting an investigation into the nature of the peculiar substances of organic origin contained in the air expired by human beings, with especial reference to the practical application of the results obtained to problems of ventilation for inhabited rooms." With this object in view, a scheme of experimentation was

¹⁴ Criminologia, p. 75.

¹⁵ See Casper, loc. cit., Kurella, p. 132.

¹⁶ Garofalo, p. 70.

¹⁷ For proof of this statement see Krafft-Ebing's early works; Beltracchi, Zur Erkennung und richtigen forensischen Beurtheilung krankhafter Gemüths-Zustände, Erlangen, 1867. References in this work to the prison work of the French alienists.

prepared by Drs. BILLINGS and MITCHELL, which scheme was carried out in the laboratory of hygiene of the University of Pennsylvania, by Dr. D. H. BERGEY. The results of the conjoint labor of these investigators has been published in the shape of a memoir which forms a fasciculus¹ in the series of "Contributions to Knowledge" issued from time to time by the Smithsonian Institute.

After reviewing the existing literature upon the subject of the effects of expired air, the results obtained from a series of new experiments are presented and commented upon. These experiments had various points in view: To determine whether expired air contains microorganisms; how much ammonia, albuminoid and oxidizable material there may be present in expired air; the effects of inoculating animals with the moisture condensed from the exhaled breath; the effects of confining various animals in glass jars, etc. These are some of the problems that the authors tried to solve.

The results obtained in this research indicate that in air expired by mice, sparrows, rabbits, guinea-pigs, or men, there is no peculiar organic poison or agent of disease. The injurious effects of such air seemed to be due entirely to the diminution of oxygen, or increase of carbonic acid, or to a combination of both these factors. In ordinary quiet respiration, no bacteria are contained in the air expired. Coughing or sneezing may throw out bacteria or other particles. The small amount of ammonia and oxidizable matter recovered from the condensed moisture of human breath appears to come from the decomposition of organic material constantly taking place in the mouth and pharynx. This fact received strong support by the differences in the amount of such matters in the air exhaled through a tracheal fistula and in that expired in the ordinary manner. The air of inhabited rooms, hospital wards, and similar places, is contaminated from many sources besides the air of expiration; the most important contaminations are in the form of minute particles of dust. The greater part of ammonia in the air of a hospital ward was shown to be connected with dust particles which could be removed by filtration. In this dust were also found microorganisms and among these some of the bacteria of inflammation and suppuration.

Experiments in which animals were made to breathe air vitiated by the products of expiration, or in which injections were made with fluids condensed from expired air, make it improbable that there is any peculiar volatile poisonous matter in the air expired by healthy beings, other than carbonic acid. It is well to recollect, however, that the results of such experiments may be applicable only in part to man. The effects of reduction of oxygen and of increase of carbonic acid to a certain degree appear to be the same

in artificial mixtures as in air in which the change of proportion of these gases has been produced by respiration. Habit may enable an animal to live in an atmosphere in which, by gradual change, the amount of oxygen has become so low and that of carbonic acid so high that a similar animal brought from the fresh air into it dies almost at once. A continuance of an immunity like this was noted for the first time in some of these experiments, especially in certain mice but this normal or artificial immunity is rare and the conditions upon which such a continuance of immunity depends are not understood. It was found that an excessively high or low temperature has marked effect in the causing of asphyxia by diminution of oxygen and increase of carbonic acid. At high temperature the respiratory centers are affected, where evaporation is checked from skin and mucous surfaces by the saturation of the air with moisture; at low temperature the consumption of oxygen increases and the demand for it becomes more urgent.

The proportion of increase of carbonic acid and of diminution of oxygen that exists in badly ventilated churches, schools, and theaters, is not sufficient to account for the discomfort which such conditions produce in many persons. There is no evidence that such an amount of change in the normal proportions of these gases has any influence upon the increase of disease and death rates which statistics show to exist among persons living in crowded and unventilated rooms. Consumption and pneumonia are the most prevalent diseases among persons living and working in unventilated rooms and these diseases are caused by specific bacteria that are adherent to particles of dust which are inhaled. The special liability of such rooms to become infected with specific germs of disease accounts for the frequency of these diseases in persons occupying crowded barracks or tenement-house rooms. Impure atmospheres may, however, affect the vitality and the bactericidal powers of cells and fluids and thus act as predisposing causes of infection. Exact scientific evidence upon these questions is lacking. The discomfort produced by crowded, ill-ventilated rooms in persons not accustomed to them is due not to excess of carbonic acid, nor to bacteria, nor, in most cases, to dusts of any kind. The two great causes of such discomfort, though not the only ones, are excessive temperature and unpleasant odors. The cause of the unpleasant musty odor of the crowded room is unknown; it may, in part, be due to volatile products of decomposition in the expired air of persons having decayed teeth, foul mouths or certain digestive disorders, and, in part, to volatile fatty acids in the cutaneous excretions and in clothing soiled with the latter. These odors may produce nausea and other disagreeable sensations in susceptible persons, but most men soon become susceptible to them.

"The results of this research, taken in connection

¹ Smithsonian Contributions to Knowledge, 989, Hodgkins Fund, Washington, D. C., 1895.

with other recent researches, indicate that some of the theories upon which modern systems of ventilation are based are either without foundation or doubtful, and that the problem of securing comfort and health in inhabited rooms require consideration of the best methods of preventing or disposing of dusts of various kinds, of properly regulating temperature and moisture, and of preventing the entrance of poisonous gases like carbonic oxid derived from heating and lighting apparatus, rather than upon simply diluting the air to a certain standard of proportion of carbonic acid present."

CORRESPONDENCE.

Typhoid Fever Treatment.

FRASER, MICH., Feb. 4, 1896.

To the Editor:—Many of the conflicting reports of Woodbridge's treatment of typhoid fever would give results similar to those obtained by Dr. Woodbridge if they would use capsules instead of tablets. Take a bottle of tablets that has been carried in your rig some time, use your tablets all out: what have you left in your bottle? About one-eighth of your tablets in powder form. I have used in fifteen cases the Woodbridge treatment and have not lost a case that I have seen in the first ten days of the sickness. The following is the record of a unique case: Mr. A. H., age 43 years. Seen Nov. 23, 1895, 3 P.M.; temperature 103.5; this continued within less than $\frac{1}{2}$ degree day and night until December 2, when he lost about three to four quarts of blood from bowel. Temperature 97 to 99 for two days; then three days of 102.5 to 103; the next day 100, then reached normal on fifth day after hemorrhage, the eighteenth day of fever. His wife and two daughters had the same (typhoid) fever; wife was sick about three weeks, daughters about fifteen or sixteen days. In conclusion would suggest: 1. Do not use tablets. 2. Capsule the medicine for the solution, leave it in a vial with a dropper and empty capsules to be used. If temperature is high I reduce temperature with acetanilid. Respectfully,

F. GROVER, M.D.,

Health Officer, Fraser, and Physician to the Poor of Erin Township.

Montana Has a State Board of Examiners.

MISSOULA, MONT., Feb. 6, 1896.

To the Editor: In your issue of February 1, in an article by Dr. C. E. Farnum, "A Suggestion that National Legislation Provide for a Medical Examining Board to Confer a Special Degree of Medicine and Surgery," he omits the State of Montana as one requiring an examination for a license from all applicants in the list of States given by him. Montana has a board appointed by the governor which requires *all applicants* to pass a satisfactory examination in all branches before they are allowed to practice and this is rigorously enforced by the board, with the result that it has kept out a host of quacks and half prepared men whose sole claim to the title M.D. consisted of a diploma. This law has also been in force for the last four years or more. Please give this notice.

Very truly yours, J. J. BUCKLEY, M.D.

Climate for Bright's Disease.

CHICAGO, Feb. 8, 1896.

To the Editor. Noticing the inquiry of Dr. Godfrey of Camden, N. J., regarding a climate for Bright's disease, I would say that, theoretically, if it be admitted, as it very generally is, that Bright's disease is primarily a nervous affection,

that the most favorable conditions from a climatic standpoint are those least stimulating to the nervous and circulatory systems. These conditions combined with soft water afford almost complete immunity from the disease among the residents of such regions. The low altitude, humid atmosphere and soft artesian water of the long-leaf pine region extending across southern Louisiana from, beginning about fifty miles north of New Orleans, to near the southern line of Mississippi, covers the above qualifications as perfectly as any region it has been my fortune to find in my study of the resorts of our country. I found in that region Bright's disease almost an unknown quantity, and I am satisfied that it will sustain the prediction that it will become very popular as a resort for kidney, skin and nervous diseases in general. There is a good hotel at Hammond, the largest town in the region, fifty-two miles from New Orleans.

A. F. MCKAY, M.D.,

Cor. Sec. World's Congress of Medico-Climatology.

Cure for Hiccough.

WASHINGTON, D. C., Feb. 3, 1896.

To the Editor:—I have found the following method a positive cure for hiccough without the use of drugs. Immediately after the paroxysm of hiccough, close the mouth and inflate the lungs to their utmost capacity by breathing the air in through the nose; then hold the breath as long as possible; when finally compelled to expel the air from the lungs we do so and to our astonishment find that we are no longer troubled with hiccough. Once usually suffices, but it may be necessary to repeat the process the second time for the reason that during the first trial at thorough inflation of the lungs there may come a slight spasm of the glottis, when we find it necessary to quickly exhale. Immediately after this sudden exhalation take a long, full breath (mouth closed) and hold it from twenty to thirty seconds. There will be positively no hiccough after such a procedure, provided the hiccough be not a symptom of some grave disease. I refer to the ordinary cases of hiccough which we see frequently in persons otherwise in good health.

W. L. ROBINS, M.D.

PUBLIC HEALTH.

Typhus in St. Petersburg.—The St. Petersburg *Med. Wochenschr.*, of January 4, reports that the epidemic of typhus there shows no signs of abating: 1,700 cases had been reported to December 21.

Decrease of Mortality Alleged to be Due to Antitoxin.—M. Monod reported at the last meeting of the Académie de Médecine, that since the introduction of antitoxin into France the mortality had decreased 65.6 per cent. He estimated that it had already saved 15,000 lives to the country.—*Gazette Méd. de Liège*, January 9.

Medical Maritime Regulations. The new sanitary maritime regulations in Italy are commended as the most modern type of improved sanitary precautions. Among them is the rule that every vessel with 150 persons on board, starting for a long voyage, must carry a physician, and two, if the passengers and crew number 1,200. The vessel owners are to apply for physicians for this purpose to certain officials who keep a register of experienced men who have been practicing at least two years since they graduated. *Semaine Médicale*, January 8.

Success of the Berlin Sanitary System. The system of sewers in Berlin is no better than elsewhere, perhaps, but the way in which their contents are carried to a distance and spread out on land owned by the city, to be purified and rendered innocuous, while serving to fertilize the ground, is becoming the admiration and envy of other municipalities. The fertilized plains bring in an income to the city, and also give employment

to the inmates of the penitentiaries, etc. There is no unpleasant odor from them, and no complaints from persons living on and near them. Among other establishments, a military school stands in the midst of these fields and the health of 800 pupils is a convincing proof of the success of the purifying process. Those interested in sanitary questions in Paris are urging the authorities there to introduce the same system, for which the conditions are far more favorable than at Berlin.—*Journal d'Hygiène*, January 2.

On the Use of Sea Water for Street Cleaning and Sewer Flushing.—According to the *American Medical Review*, January, the experiment of using sea water for sanitary purposes will soon be tried.

"The recent formation of a company in London for supplying sea water for the purpose of flushing the sewers, recalls the suggestion made by Dr. Stephen Smith, of New York, many years ago, that the streets of this city could be cleaned economically and thoroughly by that method, and incidentally the sewers would be flushed at the same time. It was pointed out to us that New York is admirably located for securing the water from the North and East rivers at comparatively small expense to the city. That part of Dr. Smith's paper seemed worthy of serious consideration, and as the question of supply of fresh water is certain to become a vital one in a few years, it will be well for our authorities to carefully observe the operations of this new London company."

An Epidemic of Measles.—The Connecticut State Board of Health *Bulletin* reports that an extensive epidemic of measles is prevailing in Westport. The public schools have been closed, but the disorder seems to have gained a general prevalence throughout the town. It is more difficult to take precautions against its spread than in other diseases, because it is more contagious than most others, and because it is contagious even before it has advanced enough to be diagnosed. It is contagious in the incipient stage, before it can be recognized as measles. No deaths have yet occurred from it, and in general it is not a fatal disease of itself. Still it is a disease much to be dreaded, because the subjects of it are rendered much more susceptible to other diseases. The children who have it recover from the disease itself, but many of them do not regain their former health, and it has been often observed that the measles was the starting point of some other disease which eventually proved fatal.

Facts from French Statistics Concerning Habitations.—The Société Française de Hygiène has been collecting statistics in regard to the dwelling houses throughout the country, and we notice that of the 9,233,725 houses in the land, 190,521 have but one opening, and 1,724,215 have only two. This means that a whole family, with its domestic animals, occupies the one-roomed cottage, and among the Alps all are housed together for six months at a time. In many villages the stables are on the ground floor and the family rooms above. In others, the stables are used as a dormitory. This was once supposed to be one of the causes of goitre, but these statistics show that there was less goitre in these communities than in others. More than half of the houses in France are owned by the occupants (5,460,355). In some districts all the liquid household refuse is given to the pigs, even including the accumulations of the night. Entire communities were found where everyone was old; the young had forsaken them for the cities. Other towns have been entirely abandoned, like the village on the Avre, whose waters were diverted to supply the city of Paris. The railroads have built up new towns, always an improvement on the older settlements, and the fishing villages along the coast are improving and prospering with the money the summer visitors leave there.—*Journal d'Hygiène*, January 2.

Smallpox in the South.—Although there have been numerous cases of variola in Louisiana, Arkansas and Tennessee, there has been a remarkably low death rate from that cause. The *Bulletin* of the Board of Health of the State last named, for

January 20, describes the course of the epidemic in two infected counties, as follows:

In Tennessee during the period from Dec. 15, 1895, to Jan. 15, 1896, there has been no case of smallpox reported outside of Memphis and Shelby County.

In Shelby County, during this period, Dr. F. S. Raymond, County Health Officer, reports in all twenty-three cases; colored, eighteen; white, five. In nearly every instance the origin of the above cases could be traced to points in Arkansas or Mississippi. In some few instances the disease was contracted from exposure to cases heretofore reported.

In the city of Memphis, during the same period, Dr. J. J. McGowan, Secretary of the City Board of Health, reports twenty-nine cases and four suspects; of these cases there were twenty-seven colored and two white, and with but few exceptions, resulting from exposure to cases hitherto reported. Thus making a total of fifty-two cases in all.

In dealing with the above cases the usual precautions were observed; all smallpox patients were removed to the pesthouse promptly, premises disinfected and a general vaccination of those unprotected was enforced.

In the counties of Lauderdale and Crockett the spread of the disease has been restricted, no new cases having been reported, and all those stricken with this disease are reported convalescing.

Sanitary Exhibition at Nashville in 1896.—The last *Bulletin* of the Tennessee State Board of Health contains a notice of the proposed elaborate exposition of sanitary appliances that is to be made at the Nashville Centennial and International Fair. The *Bulletin* says:

Beginning September 1 of this year and continuing one hundred days there will be opened in Nashville an International Exposition, which, in this country, will have been unsurpassed in its character and proportions only by the Columbian Exposition of 1893 at Chicago. The directors of "the Tennessee Centennial and International Exposition" have paid the profession the high compliment of establishing, as one of its important subdivisions, the "Department of Hygiene, Medicine and Sanitary Appliances." This, we believe, is the first time in similar undertakings in this country, that medicine, in its comprehensive significance, has had a distinct and separate department, co-equal with other leading departments, assigned it. Naturally then, as a consequence it is but reasonable to expect that the profession of our own country at least will be quick to extend its sympathy, and where possible, its active support and assistance in furthering, so far as it may, the object sought in rendering this feature a striking object-lesson of the progress made in the science and art of medicine and hygiene through the century now drawing to a close. Elsewhere in this issue will be found the organization of this department, and also the classification adopted, indicating somewhat the character and scope of exhibit contemplated in the "Section A—Hygiene, Sanitary Devices and Appliances."

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Louisiana: New Orleans, January 25 to February 1, 8 cases, 4 deaths.

Michigan: Detroit, January 25 to February 1, smallpox reported.

Tennessee: Memphis, January 1 to 31, 44 cases.

Wisconsin: Mukwonago, February 6, 1 case; Waukesha, February 6, 1 case.

SMALLPOX—FOREIGN.

Cairo, January 1 to 7, 1 death.

Cardiff, January 11 to 18, 5 cases.

Dublin, January 11 to 25, 2 cases, 1 death.

Glasgow, January 11 to 18, 4 cases.

Odessa, January 11 to 18, 3 cases, 2 deaths.

Prague, January 11 to 18, 22 cases.

Rio de Janeiro, December 28 to January 4, 28 deaths.

Rotterdam, January 18 to 25, 1 case.

CHOLERA—FOREIGN.

Calcutta, December 21 to 28, 33 deaths.

YELLOW FEVER—FOREIGN.

Ceara, December 24 to 31, 4 deaths.

Rio de Janeiro, December 28 to January 4, 76 deaths.

Sagua la Grande, January 18 to 25, 8 cases.

Tuxpan, January 11 to 25, 4 deaths.

NEW INSTRUMENTS.

A NEW BONE CUTTING FORCEPS.

BY ALLEN DEVILBISS, M.D.

TOLEDO, OHIO.

When operating on the skull, after the first opening is made, if with a trephine, it need not be more than $\frac{3}{8}$ of an inch in diameter to admit the lower jaw of the forceps. A slot $\frac{1}{8}$ of an inch wide, and as long as necessary, can be cut out, and its direction changed so as to follow the line of fracture, or cut out a piece of any size or shape. Three sides of a small or large piece, leaving the tissue attached, may be cut, breaking back

the portion left, thus making a trap-door operation of a piece so small that we would be compelled to cut away with any other forceps now used. The jaws move parallel with each other. The lower one is small enough to enter the opening in the upper one, carrying the piece cut off out, and leaving the edge smooth and even to rest on the dura. It is an aseptic instrument, as its parts can be separated from each other by removing the thumb screw A. The leverage is such that it requires much less power to use it as compared with other biting forceps, there being no difficulty in biting through the

thickest portions of the skull or rib. The stem of the lower jaw gauges the amount to be cut out each time. Side bites can be taken so that the direction of the slot may be changed without materially increasing its width. After the slot is cut an inch or so long, it is best to take a side bite out, so that the lower jaw will pass in easily and not take the time to go back to the place of beginning. There are two interchangeable jaws, one cuts deeper and wider than the other. The smallest one should be used when the bone is charnated, or when a narrow slot is desired.

BOOK NOTICES.

American Climates and Resorts. Reprint from July, 1893 to July, 1895. Comprising Proceedings of the World's Congress of Medico-Climatology, held in Chicago May 29 to June 3, 1893. 4to, cl., pp. 298. A. F. MCKAY, M.D., Editor.

This is, as stated on the title page, the reprint of the monthly publication for the period stated. Hereafter, Dr. McKay states, the annual will bear this name, while the monthly journal will be entitled *Journal of Diagnosis and Climatology*. Subscribers to the monthly will receive the annual reprint volume at the end of the year.

Sentiments of patriotism, of humanity, and not less, of native thrift indicate that Americans should develop their own resorts, instead of encouraging the annual hegira to Europe, which not only retards the improvement of our own establishments, but sends millions of dollars abroad that might well be retained. The proprietors of our own resorts have heretofore depended too much upon their unrivaled climate, and too little upon the personal comforts of their guests. The remaining at home of thousands of valetudinarians, with their dollars, is largely due to lack of information. Such publications as these are therefore to be encouraged in every way by all good citizens, not less than by the medical profession.

The book under consideration is handsomely illustrated, interesting and instructive.

NECROLOGY.

ADOLPH KIRSTEN, M.D., of Jersey City, N. J., died January 23. He was born in Germany in 1824; came to this country when a young man. He was graduated by the University of the City of New York in 1869; he practiced in Poughkeepsie and Albany for a few years, and in 1857 settled in Jersey City. He took an active interest in local affairs, and was at different times Coroner, member of the Board of Freeholders, and alderman. A widow and six children survive him.

ANNE NEWS, M.D., formerly of New York City and lately of Newport, R. I., died at the latter city on February 7, after an illness of several weeks. She was graduated in medicine in 1872, at the University of Michigan, and began practicing in Newport about twenty-five years ago, continuing until she went abroad, where she studied for two years in Heidelberg, and with Charcot in Paris. Returning to this country, she practiced in New York, and did much work in the hospital there. She then returned to Newport. She was one of the organizing members of the Newport Medical Society.

COLONEL H. ERNEST GOODMAN, Emeritus Professor of Surgery in the Medico-Chirurgical College, Philadelphia, died of heart failure on January 3, while in a train near Philadelphia, on his way to visit a patient. He had been in his usual good health, apparently, up to the moment when he was taken ill. Dr. Goodman was born in Speedwell, Pa., in 1836, and was graduated in 1859 by the University of Pennsylvania. With five brothers he served with distinction during the Civil War, and retired with the rank of Brevet Colonel. Since then he has been prominent in the Councils of the Loyal Legion, of which he was an officer of high rank. During the administration of Governor Geary Dr. Goodman was Surgeon General of the State, and subsequently was port physician. He was Surgeon to the Wills' Eye Hospital for more than twenty years, and for several years was engaged in teaching as a member of the faculty at the Medico-Chirurgical College, where he held the Chair of Professor of Orthopedic and Clinical Surgery. He was a member of the AMERICAN MEDICAL ASSOCIATION, a Fellow of the College of Physicians of Philadelphia, and also of other societies. He was very social in his tastes, and was a member of the Union League, Saginaw Club, Meade Post, Union Veteran Association and similar bodies. He married the widow of Governor Geary, who survives him, and had no children. He especially devoted himself to ophthalmic surgery, but had not contributed much to medical literature.

JOHN VAN NESS, M.D., a veteran physician of Brooklyn died suddenly from angina pectoris in the 78th year of his age. He was a native of Northville, N. Y., the son of General and Congressman Henry Van Ness. The *Brooklyn Medical Journal*, February, furnishes the following data concerning the life of a very worthy and useful practitioner:

He received his early education in the district schools and at the Academy of Northville, and then, a young man, came to

this city, and was made a teacher in the old Brooklyn Institute at a time when it numbered among its pupils many who to-day enjoy considerable distinction in various walks of life.

In 1838 he married Charlotte Rebecca Adams, of Norwich, Conn., by whom he had five children, two of whom survive him.

In 1839 he commenced the study of medicine under the supervision of Dr. Purcell Cook, of this city, and attended medical lectures at the New York University from 1843 until 1846, when he opened an office at the corner of Pearl and Tillary streets, and engaged in the practice of medicine.

Meeting with considerable success, he relinquished his position in the Brooklyn Institute, and devoted his whole attention to his new calling.

In 1852, the Medical Society of the County of Kings conferred on him a license to practice medicine in accordance with the power with which it had been vested by legislative enactment, and in 1867 the regents of the University of the State of New York conferred on him the degree of "Doctor in Medicine" on the recommendation of the Medical Society of the State of New York.

CORNELIUS GEORGE COMEGYS, M.D., at Cincinnati, Ohio, February 10, in the eightieth year of his age. He joined the Association in 1884. Extended notice will appear next week.

MISCELLANY.

The New Photography.—A Roentgen photograph enabled the surgeon to locate and remove a glass splinter that was causing trouble in the joint of a middle finger. Case exhibited at the *Verein für innere Medizin*, Berlin, January 20.

Definition of Rape in Oregon.—The criminal code of Oregon, with regard to rape, was materially changed in 1895, so that now section 1733 provides that if any person over the age of sixteen years shall carnally know any female child under the age of sixteen years, or any person shall forcibly ravish any female, such person shall be deemed guilty of rape.

Government Monopoly of Quinin in Italy.—The deaths from malaria in Italy average 16,000 a year, and in order to prevent this mortality and bring quinin within the reach of the poor and facilitate its sale in the 3,000 hamlets where there is no apothecary, the Italian parliament is considering a proposition to make the sale of quinin a government monopoly, so that it can be bought in sealed packages at the rate of 2 cents per gm. at the groceries and tobacco shops.

"A Cry from Macedonia 'Come and Help Us!'"—We clip the following from our aged contemporary, the *Medical Record*:

Boycotted.—Our esteemed contemporary, the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, has a copious supply of news from numerous minor medical centers, but religiously excludes everything pertaining to the city of New York. The isolation is depressing. Is the JOURNAL preparing to move? If so we call its attention to a pleasant town situated on an island lying off the coast of Hoboken.

Bequests to Charitable Societies.—The will of Martin Brimmer, of Boston, Mass., gives \$10,000 to the Boston Child's Aid Society. It provides that after the death of his wife one-half of his interest in the "Old Corner Book Store" property shall go to the Museum of Fine Arts, \$20,000 shall go the Massachusetts General Hospital, and \$50,000 to Harvard College.—The will of Mrs. Eliza D. Harbeck, the widow of John H. Harbeck, of New York city, leaves a considerable residuary estate to the following named three public charities, one-third part to each, namely: To the Chapin Home for Aged Men and Women, the Peabody Home for Aged Men and Women, and to the Society for the Prevention of Cruelty to Animals.

Two Oregon Laws for the Insane.—In its 1895 legislation, the legislative assembly of the State of Oregon provided for the building of a branch insane asylum on the lands selected and purchased by that State, at Union, in Union County. It also enacted that in case of the discharge or death of any person

committed to the insane asylum, the superintendent of the asylum shall at once notify the county court of the county from which such person was committed of such discharge or death, and the date and cause thereof. The county court, upon such notification, is to at once enter in the journal of commitments an order showing the discharge or death of such person, and if the superintendent of the asylum shall report any person so committed and discharged as cured, the entry of such order shall be prima facie evidence of the removal of all legal disability arising from an adjudication of insanity.

One Authentic Cure of Leprosy.—Dr. Goldschmidt, of Madeira, describes in the *Bulletin Médical*, Dec. 18, 1895, a case of leprosy cured with euophen (isobutylorthocresolidid), the only case on record, he believes. The patient showed leprosy patches on the face and limbs, which he treated with a solution of 5 grams pure euophen to 95 grams olive oil. This was rubbed into the leprosy patches with brisk friction twice a day, ten minutes at a time, for four years. It was also applied on cotton at night, with tampons for the nostrils all the time. The leprosy patches disappeared and in some places the skin healed to look normal, in others there are scars, but there is not a trace now of leprosy nor of the leprosy bacillus. The lepers' hospital at Funchal dates from the fifteenth century, when convicts and lepers were transported from Portugal and is the only one of its kind yet in the kingdom. The poverty and insufficient food of the natives favor the development of leprosy, especially as the use of the bath is unknown. Dr. Goldschmidt has published a work on leprosy and has tried every remedy without success, until this case cited above.

Tennessee's Board of State Charities.—In 1895 a Board of State Charities was created in Tennessee, the same to consist of six persons, to be appointed by the governor, not more than four of whom shall be from the same political party, and no one of whom shall be less than 30 years of age. Three years is the regular term of service. No compensation is to be allowed. The board is to investigate the whole system of public charities and correctional institutions of the State, examine into the condition and management thereof, especially of prisons, jails, infirmaries, public hospitals and asylums, and the officers in charge of all such institutions shall furnish to the board, on their request, such information and statistics as they require, and all plans for new jails and public infirmaries and hospitals shall, before the adoption of the same by the county or city authorities, be submitted to said board for suggestions and criticism. The governor may, at any time, in his discretion, order an investigation by the board, or a committee thereof, of the management of any penal, reformatory or charitable institution of the State.

Dislocation of the Spine and Consequent Hyperpyrexia.—A woman of 40 was brought to the hospital at Schaerbeek, who had fallen backward in the course of her work, from a height of 1½ meters, striking a solid horizontal bar about the region of the kidneys. Health previously was invariably fine. The fall produced a luxation between the sixth and seventh cervical vertebrae, showing the spinal marrow, as the autopsy disclosed a complete diastasis of the two vertebrae. The lower limbs and muscles of trunk were completely paralyzed, pulse 120, respiration exclusively diaphragmatic. The unusual feature of the case was the sudden and excessive rise of temperature. One-half hour after accident it was 36.5 degrees C. In twelve hours it was 39 degrees, and in twenty-four hours it rose to 43 degrees, when death ensued. Dr. Lambotte, who described the case in the *Presse Méd. Belge*, No. 50, draws the conclusion from it that there must be some nerve center in the region of the sixth or seventh vertebra which acts with great energy to control or modify the temperature of the organism. Destroyed by some lesion this center ceases to act as moderator of the temperature, which then rises unchecked, as is proved

by the hyperpyrexia following this accident so immediately and to such an excessive extent. No possible infection could have occurred in this case and consequently it proves that fever is not necessarily of microbial origin, but may result from some lesion of a caloric nerve center. — *Bulletin Méd.*, Jan. 12, 1896.

The "Surgeon's House" at Pompeii. The *Medical Press and Circular* has made the following condensed statement regarding the recent article of Prof. Nicholas Senn on his medico-historic researches in Southern Italy:

"Nearly two thousand years have elapsed since the Pompeian surgeons practised their art in their ill-fated town, and yet many objects of interest to the surgeon have since then been brought to light during the vast excavations undertaken for the purpose of exposing the ruins of Pompeii. In an interesting paper on this subject in the last number of the *Philadelphia Medical News* Dr. N. Senn gives a description of a recent visit that he made to the ruins of Pompeii and the Naples Museum, and enters fully into the account of what he saw in the nature of Pompeian surgical instruments. The instruments were found in a house which has been called the "Surgeon's House." They are made of bronze, and some of them show a high degree of workmanship. Some of them indicate also the destructive effect of heat and oxidation, while others are in a careful state of excellent preservation. Careful search was made among the instruments for traces of needles or any appliance which would indicate that at that time wounds were sutured. But nothing of the kind was found. The collection, moreover, did not contain any saws, trephines, chisels, or instruments for operations upon bones. Again, with the exception of the specula and catheters, it is curious to note that the instruments were of a diminutive size in comparison with those of less remote and more modern times. Judging from his instruments, the Pompeian surgeon plainly confined his 'cutting' operation to bleeding, cupping, extraction of foreign bodies, and the opening of abscesses. Dr. Senn concludes his paper by pointing out that the surgeon of Pompeii must have been a man of means and good social position: the position of his house in the most aristocratic part of the city, and its capaciousness, both testify to this fact. A liberal income, therefore, probably rewarded his labors and placed him in a position to enjoy the luxuries of life, which seem to have been the main object in life of the mass of the Pompeian people before the destruction of their city."

Practice of Medicine in West Virginia. Chapter seven. There shall be a "State Board of Health in this State consisting of two physicians residing in each Congressional district thereof, who shall be graduates of reputable medical colleges and who shall have practiced medicine for not less than ten years continuously; they shall be appointed by the governor and shall hold their office for the term of four years unless sooner removed. . . . who may practice medicine in this State, all such persons as shall be legally entitled to practice medicine in this State at the time of the passage of this act. All such persons as shall pass an examination before the State Board of Health and shall receive certificates from the said board to that effect as hereinafter provided. . . . Examinations to be practical, written and oral and not less than three to be held during the year. . . . The President and Secretary to sign and issue certificates to all who successfully pass the examination, and such certificates shall be deemed license to practice in this State. No applicant for license to practice medicine in this State shall be rejected because of his or her adherence to any particular school or theory of medicine. The State Board shall call to their assistance, in the examination of any applicant who professes the homeopathic or eclectic school of medicine, a homeopathic or eclectic physician duly licensed or qualified to practice medicine in this State." . . . The members of the State Board of Health are as follows: W. P. Ewing, M.D., Charleston, President; N. D. Baker, M.D., Martinsburg, Secretary; J. B. Walkinshaw, A.M., M.D., Wellsburg; L. D. Wilson, M.D., Wheeling; G. P. Dailey, M.D., Romney; W. C. Beard, M.D., Alderson; H. R. Barbee, M.D., Pt. Pleasant. Next examination at Clarksburg, on April 28, 29 and 30, 1896.

Changes in Oregon Pharmacy Law. The Oregon legislative assembly in 1895 made a number of changes in the law which it passed

in 1891, to regulate the practice of pharmacy and sale of poisons. First of all, that portion of Section 1, allowing persons other than registered pharmacists to compound or dispense the prescriptions of physicians, or to retail or dispense poisons for medical use, as an aid to and under the supervision of a registered pharmacist "or registered physician," has been changed by omitting the three words put in quotation marks. Section 7 is amended, requiring an assistant or clerk in pharmacy, in order to become registered as a registered pharmacist thereunder, to be of good moral character, to be of the age of 18 years, to be examined by the board of pharmacy, to pay a fee of \$5.50 a year thereafter for a renewal of his certificate. Section 8 is amended requiring every registered pharmacist during the time he continues the practice of his profession in the State to annually and on such date as the board of pharmacy may determine, pay to the secretary of the board a fee of \$1, for which he shall receive a renewal of his registration. Section 10, relating to the retail of poisons, is amended by naming a number of them, and preparations made from them, for greater certainty as to the scope of the law, which is better on this point than the law of some older States. Not only is the principal of the store which violates this section liable to a fine therefor, but the "owner, manager and principal," is now the more comprehensive designation used. But it is provided that nothing herein contained shall apply to the dispensing of physicians' prescriptions of any of the poisons aforesaid. Section 11 is amended, after excepting from the provisions of this act, the manufacture or sale of proprietary or patent medicines, by striking out the words "nor prevent shop-keepers from dealing in and selling the commonly used medicines and poisons, if such poisons and medicines are properly labeled." All actions for the recovery of penalties are to be prosecuted by the district attorney of the proper county, upon the relation of himself, or any member of the board, and all penalties collected are to inure, one-half to the board of pharmacy, and the remainder to the county treasurer for the use of the school fund.

Suicide as a Fraud upon Insurers.—Willful self-destruction by the insured, when he is sane, the United States circuit court of appeals brands as a fraud upon the insurer, whether the purpose to commit the act is formed before or after the policy is taken. It is a fundamental condition of the contract of life insurance, even if the policy be silent on the subject, the court holds, that the insured, while in a sound mental condition, will not voluntarily destroy his life. In the cases brought to the court's attention, where suicide, during sanity, was held not to be a valid defense, it says the policy was issued for the benefit of some other person, or an independent interest, by assignment or otherwise, had been acquired by a third person. Not one of the decisions, it thinks, gives countenance to the idea that the personal representatives of the insured can recover where the latter, while sane, deliberately commits suicide for the purpose of compelling payment of the insurance money to his estate, though the policy contain no provision with respect to suicide. But this precise question, it would seem, was not involved or decided in any case prior to the present one, of *Ritter vs. Mutual Life Insurance Company of New York*, decided Dec. 2, 1895. And here the court holds that in such case there can be no recovery, as to sanction one would be to reward fraud and wrong-doing. Some interest also attaches to the instruction which was given to the jury, that if one who intentionally kills himself when his reasoning faculties are so far impaired by insanity that he is unable to understand the moral character of his act, even if he does understand its physical nature, consequence and effect, such self-destruction will not of itself prevent recovery upon the policies. Care, it was suggested, must be exercised not to misunderstand the term "moral character of his act," as intended to be used. The domain of metaphysics was not to be entered. If the insured understood what he was doing, and the consequences of his act or acts to himself as well as to others, in other words, if he

understood, as a man of sound mind would, the consequences to follow from his contemplated suicide, to himself, his character, his family and others, and was able to comprehend the wrongfulness of what he was about to do, as a sane man would, then he was to be regarded as sane; otherwise, he was not. It is held there was no error in this charge or explanation.

Burden of Proof as to Sanity.—No, most decidedly *no*. That is practically the answer which the supreme court of the United States gave Dec. 16, 1895, to the important question: "If it appears that the deceased was killed by the accused under circumstances which, nothing else appearing, made a case of murder, can the jury properly return a verdict of the offense charged if, upon the whole evidence, from whatever side it comes, they have a reasonable doubt whether, at the time of killing, the accused was mentally competent to distinguish between right and wrong, or to understand the nature of the act he was committing?" This was a case styled *Davis vs. United States*, which originated in the western district of Arkansas. In other words, the supreme court here set aside a conviction of murder, was based on the idea that the defense of insanity made could not avail the accused unless it appeared affirmatively to the reasonable satisfaction of the jury that he was not criminally responsible for his acts. Now "to make a complete crime cognizable by human laws, there must be both a will and an act." The plea of not guilty controverts the existence of every fact essential to constitute the crime charged. Upon that plea the accused may stand, shielded by the presumption of his innocence, until it appears that he is guilty; and his guilt can not, in the very nature of things, be regarded as proved, if the jury entertain a reasonable doubt from all the evidence whether he was legally capable of committing crime. On principle, therefore, the supreme court holds that the burden of proving that the accused belongs to a class capable of committing crime rests upon those who affirm that he has committed it. The burden of proof is on the prosecution from the beginning to the end of the trial and applies to every element necessary to constitute the crime. Giving to the prosecution, where the defense is insanity, the benefit in the way of proof of the presumption in favor of sanity, which is a disputable presumption, the vital question, from the time a plea of not guilty is entertained until the return of the verdict, is whether upon all the evidence, by whatever side adduced, guilt is established beyond reasonable doubt. If it is not, the accused is entitled to an acquittal. Such, in brief, is the position taken by our highest court, with no dissenting voice. But, before leaving the case, Mr. Justice Harlan says that it seems to him that undue stress is placed in some of the cases upon the fact that in prosecutions for murder the defense of insanity is frequently resorted to, and is sustained by the evidence of ingenious experts whose theories are difficult to be met and overcome, so that often the most atrocious characters often go unpunished, and the public safety is thereby endangered. But the possibility of such results, the court says, must always attend any system devised to ascertain and punish crime, and ought not to induce the courts to depart from principles fundamental in criminal law, and the recognition and enforcement of which are demanded by every consideration of humanity and justice.

The Pineal Eye.—The pineal gland, by reason of its impaired median condition, its situation at the entrance of the cerebral cavities and its ribbon-like peduncles have always excited the curiosity of observers, and without knowing its structure they have attributed the most dissimilar functions to it. Galen, combating the opinions of his predecessors, who believed it to be a door for the mind, asserted that it only served to join the two veins which he described in the choroid plexus. The celebrated philosopher, René Descartes, located the seat of the soul here. For he said the rest of the brain is bilateral, and we have two hands, two eyes, etc., while we have only a single

perception of the same thing at one time. Now, there must be a place where the two impressions we get from the double organs of our senses were joined in one before reaching the soul. As the pineal gland answers the requirements it must be the principal seat of the soul. Margendie believed it to be the valve regulating the flow of the cerebro-spinal fluid. While these theories are very interesting we are more concerned at present in the question whether this "gland" has any connection with a median impaired eye of a far distant ancestor. More recent anatomic studies have shown that this organ exists in all vertebrates, occurring with annoying persistence from man through the series of vertebrate brains down almost to that miserable travesty, the lancelet. It is more developed in fishes and reptiles than in mammals, it appears at an early period in man (about the fifth week) and arises in the same fashion in all animals, as an epithelial invagination from the thalamencephalon, the brain which gives rise to the optic tracts and to the middle ventricle. As far back as 1868 Leudig recognized the sensorial nature of this organ and called it the "frontal organ" and Götte showed it to be identical with the epiphysis. Rabl-Rückhard in 1882 advanced the hypothesis that it might be a visual organ, or one for a thermic sense belonging to animals of past geologic epochs. In 1886 Dr. Graaf discovered a crystalline and vitreous in the epiphysis of lizards, and his discovery has been confirmed and extended by Baldwin Spencer. Early in the development of the vertebrate brain a median hollow diverticulum juts out from the roof of the thalamencephalon. It is generally found persistent through life as a long tube, but sometimes the distal end becomes lobular and consists of a number of follicles. In man and other mammals these follicles become more or less solid forming the pineal gland. Among lizards we find this body presenting all the characteristics of an eye. In this group the pineal eye is most completely developed in the *Hatteria* or *sphenodon*, an almost extinct lizard of New Zealand. Here we have an optic vesicle, a crystalline lens, a retina and an optic nerve, the interior of the vesicle filled with transparent tissue, the vesicle is situated in a median foramen in the parietal bone, outside the cranial cavity, and covered only by the skin, through which it may be recognized by a modified scale without pigment, easily distinguished from the rest of the dermal covering. In other genera of lizards the eyes become more and more rudimentary until in *seps*, *anguis*, etc., the nerve does not connect with the eye. This eye should be present in forms lower than the reptilia, the amphibia and fishes. While it is present in the extinct amphibia its existence in fishes is yet uncertain. Dean¹ thought that in *dinichthys*, a fossil fish from the Devonian, a median opening in the head enclosed a pineal eye, but in a more recent work² he abandons this view. In bird and mammals the epiphysis is completely degenerated and inside the skull. Its function in ancestral vertebrates is supposed to have been to allow the possessor to look up while lying partly buried in mud or sand, and as the paired eyes developed, this degenerated. In man the epithelial vesicle ramifies into tubes, the connective tissue capsule surrounding these strangles them so to speak, and closes them off into independent cavities. The degeneration of the organ is manifested not only by the cystic formation and by the pigmentary infiltration, but also by the almost constant presence of calcareous concretions in the gland itself, its peduncles or in the neighboring choroid plexus (Charpui). There is no essential difference between the pineal gland of man and that of the anthropoid apes. So then, we have a structure whose functioning in extinct saurians and some of their descendants of the present day, has degenerated and retreated within the skull, and its origin or purpose would be a mystery were it not for the light afforded by comparative anatomy and embryology. If the pineal

¹ N. Y. Rept. on Fisheries, 1891, p. 310.
² Fishes, Living and Extinct, 1895, p. 55.

gland and eye arises singly from the train it will modify some of our ideas concerning the origin of the paired eyes. The latter are by most modern biologists believed to be derived through evolution from the segmental sense organs of invertebrates. Organs for the perception of the senses are divided into lower and higher. In the former are the tactile sense organs and in the higher those for vision, olfaction, audition, and gustation. It will be noticed that these higher organs are all situated in depressions specially provided for them in the head. It has been found that though the gulf between tactile and visual impressions is great, it has been bridged by some of the annelids (leeches, etc.). In these organisms we find pure tactile cells at one end of the body, and pure visual cells at the other with a mixture of the two in the middle, or we may have all the tactile cells changed into visual. While search is being made for confirmation of this hypothesis in other classes of animals, the pineal eye presents a grave objection to this view, for the segmented sense organs are all double and if the pineal gland proves to be of single origin, two of these segmented organs must have coalesced to form it. At this juncture Loey comes to the rescue. This author³ from a study of shark embryos believes that in addition to the two optic vesicles for the paired eyes, two pairs of accessory vesicles appear at an early stage of development. This requires further study and if confirmed would go to prove that the pineal eye was paired also. In this connection it may be noted that the chitons, or coat of mail shells, possess numerous ocelli on their shells, a fact discovered in 1884 by the lamented Mosely. One species *Corephium aculeatum* has over 12,000. In some genera the eyes are scattered about irregularly over the shell, in others they are arranged symmetrically, the latter form is looked upon as being a later development from the earlier irregular distribution. At the present writing while waiting further investigations we have strong reasons for believing that our primitive hermaphrodite gill-bearing ancestors had eyes in the "back of their heads" as the proverb says.

Practical Notes.

Purgatives and Milk as Antiseptics.—Experiments recently made on the antiseptic action of purgatives show that it is temporary although thorough while it lasts. But a continuous diet of milk produces almost absolute asepsis of the alimentary canal slowly and progressively, which lasts as long as the lacteal régime is kept up.—From paper read before the Société de Biologie, and reviewed in the *Gazette Méd. de Paris*, January 4.

Ozone in Whooping Cough. The *Bulletin Médical* of January 8, reports twenty-two cases of whooping cough treated with inhalations of ozone. It acted immediately in diminishing the frequency, the length and severity of paroxysms; it shortened the course of the disease remarkably and the general health improved at once, although the cases treated were all severely attacked.

Instantaneous Process for Sterilizing Cotton. An absolutely aseptic tampon can be made of any piece of cotton by twisting it on a stick or toothpick and dipping it into an alcoholic saturated solution of boracic acid for a moment. Applying a light to it the alcohol burns out, while the boracic acid prevents the cotton from burning. Five seconds are enough: as soon as the flame turns green it is extinguished. The cotton is still white, dry, scarcely warm, but absolutely sterilized. *Gazette Méd. de Liège*, January 2.

Method of Inserting Artificial Ureter. Boari, of Ferrara, writes to the *Policlinico*, No. 19, 1895, reviewing all the cases recorded of artificial ureters, and describing his experiments with dogs, and successful operations in two clinical cases. He uses a button similar to the Murphy button, to which is fastened a tube that is introduced and fastened in the ureter. The intestine is opened with a lengthwise slit, through which the

button is inserted. The membrane of the intestine and the ureter can be sewed together for security. In one case the operation was performed for tuberculosis of the bladder, and in the other, on account of a large vesico-vaginal fistula, with destruction of the ureter. The button was evacuated in eight to twelve days.—*Centralbl. für Chir.*, January 4.

Thioform in Surgery and Dermatology.—The tendency in modern surgery is to keep the diseased parts as dry as possible, and for this purpose thioform is highly recommended by Dr. Buck, of Ghent, to use in connection with iodoform, which it does not supplant but supplement. He uses it as a powder, either pure or combined with an equal part of boracic acid. He has also administered it internally in cases of enteritis, in doses of 2 grams for an adult and $\frac{1}{2}$ to 1 gram for a child. Its constipating and antiseptic effect was manifested in each case. The *Gazette Méd. de Liège* of January 23, devotes considerable space to his study of thioform, which he asserts is of great value in gastro-intestinal disturbances as well.

Primary Sarcoma of the Pleura.—A Russian surgeon writes to the *Deutsch. med. Wochen.*, of January 23, reviewing the only five cases of this kind on record known to him, and describing in detail another that occurred in his own practice. A young man of 23 came to him suffering from pain and oppression in the pleural region, and other symptoms plainly indicating pleurisy with effusion, but still differing from it by the enlargement of the thorax, persistence of dullness on percussion with every change of position, and especially by the cachexia and radiating pains. Death ensued from sudden asphyxia and the autopsy confirmed the diagnosis of primary sarcoma of the pleura. It weighed about seven pounds, had grown to the spine and posterior thoracic wall, and was round-celled. A noticeable fact in these cases is the youth of patients.

A New Intestinal Button.—A new anastomotic button for intestinal operations was recently exhibited at the Soc. de Chirurgie de Paris, by Dr. Chaput, which he asserts is an improvement on the Murphy button. It is made of pure tin, in the shape of an elliptical ring, the hole in the center being 5 mm. wide and 30 long. The side view shows a circular groove, 1 c. wide and 8 mm. deep. The rims of the groove are cut in three places, and are thin enough so they can be pressed together with the fingers. There are four different kinds made, for the four principal kinds of operations where it is needed. It has given excellent results in several cases where it has been used, notably in cancer of the stomach and transverse colon and also in stenosis of the pylorus, although in one case the two buttons used have not been evacuated.—*Gazette Médic. de Liège*, January 9.

Erysipelas Serum as Treatment for Cancer.—Prof. Kopfstein treated fifteen cases of malignant cancer with serum of his own make and found that unpleasant symptoms were produced in every case with no alleviation of the disease. (*Wien. klin. Rundschau*, Nos. 33 and 34.) The *Centralbl. f. Chir.*, Jan. 11, 1896, commenting on Kopfstein's article remarks that his experiences prove nothing for or against the Emmerich serum, as Kopfstein took his from an animal after one injection, while Emmerich and Scholl produced a chronic state of infection by repeated injections, before they took the serum. In the same magazine a case of cancer of the breast five years in development, is described by Dr. Schüler, who treated it with the Emmerich-Scholl serum, after lancing. The patient improved from the first and the abnormal growth nearly entirely disappeared, while patient, a woman of 47, gained fourteen pounds. This may possibly have been some cancerous tumor and not a true carcinoma, judging from author's description.

Cutting and Tying the Vas Deferens for Hypertrophy of the Prostate. Chalot, of Toulouse, and Isnardi, of Turin, have each performed successful operations for senile dysuria this last year by tying the vas deferens and cutting it instead of castrating.

Isnardi writes to the *Therapeutische Wochenschrift* of January 12, describing his operations in detail. He claims that this is enough in most cases, but if castration is found necessary, it is a preliminary that much facilitates the latter. His method is to cut the vas deferens, tie the stump ends and insert them in the incision so that as it heals they will grow into it. The atrophy produced will be much speedier and more radical if the plexus spermaticus is cut, and a slight inflammation of the spermatic cord produced. He believes that neurotomy will in time be found such an important factor in producing atrophy that it will be proved sufficient alone. Chalot exposes 2 cm. of the vas deferens and applies two ligatures of fine silk, $1\frac{1}{2}$ cm. apart and then cuts it between them. His operations are described in the *Revue Internationale* of January 10. One performed in February 1895 reduced the prostate gland to half its size, while the genital functions were not disturbed.

Abdominal Massage to Relieve Habitual Constipation.—Dr. Kümmmerling uses the following process of massage for this purpose which is far more efficient than the usual process. Massage lasting fifteen minutes, well done, is sure to produce an easy and abundant evacuation. The patient is placed on his right side and the operator picks up with his thumb and index of each hand the skin and the subcutaneous tissue at the level of the iliac spine. This makes the intestine directly accessible to the other fingers, and he manipulates it with them, always pressing from above downward, and with the ends of his fingers, for five minutes. Then the patient is turned on his left side and the process is repeated on the cecum and the ascending colon, only in the opposite direction, from below upward. This leaves only the small intestine and the transverse colon to be massaged, for which the patient is placed in the decubitus genupectoral position, as this relaxes the abdominal walls and brings the intestines closer into the hand of the operator. *Sem. Méd.*, Dec. 5, 1895.

Method of Preparing Bone Marrow for the Treatment of Pernicious Anemia.—Dr. Alfred Barre, of Leeds, England, offers in the *British Medical Journal*, the following suggestions as to the preparation of bone-marrow: "Three ounces of fresh bone-marrow (as much red as possible) are made into a paste with port wine, one ounce; gelatin, five drachms. A little care is required in making the paste, to keep the gelatin and the marrow sufficiently fluid for them to be thoroughly mixed. The gelatin should be soaked in sufficient water to soften it, and then should be melted with the glycerin, the mixture being kept in a mortar previously made hot with boiling water, while in another mortar, made hot in a similar manner, the marrow and wine are mixed. Then the contents of the two mortars should be thoroughly incorporated and allowed to set." The hospital meat-purveyor seems to have no difficulty in supplying the marrow free from spicules of bone. To some patients the mixture of glycerin, or the mixture of glycerin and marrow fat, is distasteful. For some of these, the objectionable taste is to be overcome by the addition of a small quantity of water at the time of the exhibition of the remedy.

Eruptions Following the Use of Quinin. (Idiosyncrasies.)—The extensive experience of Dr. Dubergé, former physician in chief to the French navy, gives importance to his article on quinin, reviewed in the *Gazette Méd. de Liège*, of January 2. He considers its action on the heart pernicious and its use contra-indicated in affections where the heart needs all its energy and activity. Amblyopia is also produced very rarely by quinin, it develops rapidly and may result in complete blindness. Deafness follows its use in very rare cases, but the transient effect soon passes off. It may also affect the brain, but this is never an important trouble. It may produce gastro-intestinal disturbances, vomiting and diarrhea that are sometimes fatal. It has also affected the genito-urinary organs, producing pain, oliguria, retention of urine, albuminuria, hematuria, menstrual

troubles and abortion. He concludes his list of possible evils due to use of quinin with eruptions, which he says are either simple erythema or eczema. It is a coincidence that the *Annales de Derm. et de Syph.*, December, 1895, contains a detailed description of a case of extensive bullous erythematous eruption that appeared every time patient took quinin and vanished as soon as it was discontinued, as was demonstrated by repeated experiments. Patient had been syphilitic in years past and the eruption was treated for syphilis a long while. When it was traced to use of quinin, cure resulted immediately.

Subcutaneous Injections of Sublimate as Cure for Cerebro-Spinal Meningitis.—An Italian, Dr. Dazio, suggested this treatment, and with it Dr. Consalvi, of Casoli, has recently treated successfully nine cases occurring in an epidemic of influenza. (*Sem. Méd.*, Jan. 15, 1896.) The quantity of sublimate injected varied from .005 millig. to .01 centig., according to age of patients, which were from 14 months to 19 years. He made at first one injection in twenty-four hours, and later one in forty-eight. One case alone proved fatal, a girl of 7 died after first showing temporary improvement after injection. In other cases vomiting ceased after second injection, followed by disappearance of other symptoms, except the muscular rigidity. This persisted until after the sixth to eighth injection in some cases. The injections restricted the disease to a moderate intermittent fever with slight headache. The sublimate produced no disturbance except in two cases, one a girl of 14 had a slight attack of mercurial stomatitis after tenth injection, and another girl of 7 a bloody diarrhea after the fifth, but both soon passed away. Besides the sublimate, Dr. Consalvi used leeches, ice, frequent purgations with calomel, and bromid or morphin to quiet the patient. As recovery progressed he gave them iodid of potassium to expel the mercury from the system and favor the absorption of the meningitic exudations.

Thyroid Extract Successfully Used in Stupor, and in Ichthyosis.—The *Montreal Medical Journal* contains references to two new uses for thyroid extract, or thyroid feeding. One of these uses was the subject of a paper before the Canadian Medical Association by Dr. Charles Kirk Clarke, medical superintendent of the Rockwood Asylum for the Insane at Kingston. "He stated that he had observed, as others had done before, the effects of acute disease on these cases of stupor, how that it benefited many, in some cases effecting a complete cure. In the first case reported in his paper the patient was almost a hopeless dement. Upon the administration of the thyroid extract improvement began and gradually progressed until the cure seemed to be almost complete, when suddenly the patient, without apparent cause, relapsed back into his former condition. In other cases, however, the writer reported the effects to be well marked, a permanent cure resulting. The doses given went as high as 20 grains." Dr. W. E. Deeks has reported to the Montreal Medico-Chirurgical Society a case of ichthyosis for the relief of which thyroid extract was employed. The remarks of Dr. F. J. Shepherd, made in the discussion of the paper, indicated the propriety of having the case continuously under observation. He said: "Ichthyosis is of course a congenital affection, or at any rate comes on soon after birth. If this case was cured by thyroid extract it is certainly remarkable, and another triumph is added to the many now claimed for this wonderful remedy. Cure of ichthyosis is almost unknown, though temporary amelioration may always be obtained by the daily use of soap tinctures followed by the rubbing in of any fatty matter. The case is well worth reporting and following up, and Dr. Deeks should, if possible, bring her before the society, or report the progress of the case after several months have elapsed."

Behring on Serotherapy. For the first time Professor Behring has replied to the critics of antitoxin and supports the efficacy of this discovery by innumerable statistics. (*Deutsch. Med.*

Woch., 1895, No. 38). He claims that even statistics do not do it justice, as it is used in perhaps the more desperate cases, and the mortality percentage is therefore higher than it should be in proportion. But even allowing for countless errors the percentage is a great gain over the past. The mortality in Berlin in 1895, sank to 15 per cent., two-thirds less than it had averaged during the seventeen years preceding, while the character of the diphtheria was more serious than at any time since 1886. Of 10,312 cases, 5,833 were treated with serum, with a loss of 9.6 per cent. while 4,479 cases treated without it, showed a mortality of 14.7 per cent. The percentage fell to 10.3 per cent. in the Contagious Disease Institute, where the serum was exclusively used.

He asserts that the question now is: Shall it be used to secure immunity? For this purpose he recommends one-half of a regular dose. He says the works can now supply 100,000 doses a month, which barely keeps pace with the demand from Europe and America. Improved methods have enabled the dose to be concentrated from 5 c.c into 1 c.c. He regrets that the specific for tuberculosis is not yet all that was hoped for it, but congratulates Ransom on his cholera serum and Knorr on his for tetanus. *Centralbl. für Chir.*, January 11.

Low Death Rate in Typhoid Fever Treated by the Cold Bath.—Dr. William Osler has recently given before the Canadian Medical Association the result of five years experience with this form of treatment. He stated that when the patient's temperature rose above 102.5 F. he was placed in a bath of 70 F. every third hour. To patients with heart weakness strychnin and alcohol in small doses were given, particularly after the bath. Milk, broths and egg albumin constituted the diet. Three hundred and fifty-six cases had come under treatment in the hospital, with twenty-five deaths. The mortality was 7.02 per cent. of all cases, and 6.3 per cent. of bath cases. It was to be remembered that hospitals were usually given the worst cases. In certain cases the baths were contra-indicated—as where the temperature did not rise to 102.5 in very mild cases, in cases markedly asthenic: and where serious complications were present, as hemorrhage, perforation, etc. So that the Brandt method had not been strictly followed. The beneficial effect was not wholly due to the antipyretic action, but to the general tonic effect. Although not in favor of the treatment at one time, he had become an advocate of it, having seen its good effects in his own cases, as well as in those of the large hospitals in other portions of the globe. From statistics gathered it gave better results than any other form of treatment.

Dr. Muir, of Truro, N. S., referred to annual epidemics of typhoid he had experienced following river freshets. He pointed out the difficulties of carrying out the cold bath treatment in private practice, of the opposition of the patient's friends, and of the danger to the medical man's reputation if serious results followed the cold baths. He condemned the use of the ordinary antipyretics. His watchword was, watch the pulse, not the temperature. The speaker said that most of his patients died from bowel complications. To avoid constipation he used small doses of Rochelle salts, and for an antipyretic, alcohol. His death rate was 8.1 in 159 cases.

Urticaria and Jaundice Associated with Ptomaine Poisoning. In the London Post Graduate course, conducted by Mr. Jonathan Hutchinson, as reported for the *Medical Press*, that teacher brought before the class the following case of partridge poisoning, or poisoning after partridge. Partridge poisoning, as observed in this country and in Canada, is seldom referred to by English writers: "The patient was a man, aged about 35, who came with the following history: About fourteen days ago he ate some cold, over kept partridge. In the course of a few hours afterward, he felt sick and unwell. For three days the sickness continued, and then the attack of urticaria supervened. The attack was an unusually severe one, all the patches

were salmon-tinted, and for a week no improvement could be noted. At the end of that time, however, the patches began to disappear, and when this occurred, the patient quickly became deeply jaundiced. The skin was now stained a deep yellow, and the urine was discolored from the presence of bile. A point of much interest in this case was the association of urticaria with the jaundice. It was worthy of note that inflammation of joints sometimes occurred in connection with urticaria. The probability was that when this was the case the patients were the subjects of inherited gout. An instance of this kind had recently come under Mr. Hutchinson's notice. The patient, who was suffering from urticaria, complained of some inflammation of his knee-joint. He was aged 35, and Mr. Hutchinson found tophi on his ears—not ordinary tophi, calcareous, containing some deposit of urate of soda, but more of a fleshy character. The patient's brother had been shown, at a former demonstration, suffering from Dupuytren's contraction of the ring and little finger of the left hand. Although the contraction was attributed by this patient to a severe dog-bite of the hand, there was, on the other hand, very little doubt that the deformity was more largely due to inherited gout."

Neuritis During and After Typhoid Fever.—In the Johns Hopkins Hospital Reports, Vol. v, No. 6-9, 1895, Professor Osler gives an account of the cases of neuritis during and after typhoid fever that have come under observation during the six years ending May 15, 1895. The cases may be grouped into instances of local neuritis and of wide-spread, diffuse, multiple neuritis. Among 389 cases of typhoid fever under treatment there were four with well-defined symptoms of a local neuritis. In two the neuritis developed during the height of the fever. In Case 1, severe neuralgic pains in the arms with great tenderness of the muscles developed in the second week; there was numbness of the hands, no arthritis and no sensitiveness of the nerve trunks; the patient recovered without washing. In the second case there developed severe pains in the right arms and legs in the third week; the arm improved rapidly, but the pain in the leg became agonizing; there was great sensitiveness in the muscles with erythema nodosum; recovery took place after ten days. In two cases the neuritis developed after the subsidence of the fever. In the first case there was pain in the left leg, sensitiveness in the nerve trunks and soreness in the tibialis anticus; the recovery was quite rapid. In the second case the onset of convalescence was marked by the development of soreness and pains in the limbs, especially the arms; "pins and needles" in the left foot and swelling with tenderness in the left arm; the improvement was gradual and recovery took place without atrophy. Osler then describes the clinical features of four cases of multiple neuritis following typhoid fever in which there was a rapid or gradual development of paralysis of the legs or of both arms and legs. In such cases the differential diagnosis lies between peripheral neuritis and anterior poliomyelitis and this is often difficult. The following are some of the more important points: The mode of onset is very much more rapid, as a rule, in myelitis. In poliomyelitis the sensory symptoms are subsidiary, whereas in polyneuritis there is more or less pain, or sensations of numbness and tingling. The atrophy is more rapid in the central lesion. The gradual recovery of the faradic irritability of the muscles is a point which favors the diagnosis of neuritis. The most important of all points is the subsequent history, because complete recovery is almost the rule in multiple neuritis. The prognosis is consequently in the main good. In treatment persistent massage is very important; medicines are of doubtful utility; from twelve to eighteen months time is the essential factor.

Osler also calls attention to a very interesting and distressing affection which he thinks should be classed as a neuritis, namely the tender toes of typhoid fever. Handford, quoted in Rose and Bury on "Peripheral Neuritis" (London, 1893), says in describing this feature: "For some weeks past there has been tenderness of the toes of both feet, so that the toe nails could not be cut on account of the pain it caused in the nail bed and in the pulp at the end of the toes. In three other

cases recently I have met with this condition of pain in the toes and in one of them in the arms also. In one instance the tenderness of the feet was so great that they had to be protected from the pressure of the bed clothes by a cradle. But in none of them was it followed by muscular wasting or definite loss of sensation so far as I could detect." Osler does not think that this condition is an effect of the cold water treatment. The treatment of such tender toes is not very satisfactory. Hot cocain solution or cotton wool seems to give most relief.

Hospital Notes.

THE TWENTY-SEVENTH ANNUAL REPORT of the Children's Hospital of Boston, has just been issued. The Board of Managers justly claim great success for the institution and in its relation to the city of Boston they assert that "Our own hospital offers the example of hundreds of children and young persons, moving about among us, with the hope and the certainty of continued life and the power adequately to meet the world, in place of that invalidism which seems to be the heritage of so many of the human race. It is thought best to make this statement at this time in order that the patrons of the hospital may recognize the importance of, and may be tolerant of, the demands made on them to carry out the good work.

"We can point to the fact that the presence of cases of club-foot and crooked backs and lame legs is noticeably less on our streets than it was twenty years ago; we can show that the children of to-day in our midst are stronger and better able to cope with the roughness of life; we can make evident that this improvement is due, partly to our own hospital, partly to the advanced intelligence of physicians who have studied in our own and similar institutions and are spreading over the land the newer lights of medical knowledge."

In regard to antitoxin in diphtheria, the report, while stating that as a rule contagious cases are not admitted to the hospital yet epidemics in the institution have apparently been stopped by its use, and they invite attention to Dr. Morrill's report of that subject, in the *Boston Med. and Surg. Journal*.

Detroit Notes.

THE WAYNE COUNTY Medical Society at its regular meeting Thursday, February 6, listened to a very interesting paper by Dr. W. R. Henderson entitled, "Rupture of the Uterus."

AT THE REGULAR MEETING of the Detroit Medical and Library Association Monday, February 3, Dr. T. A. McGraw read a paper entitled, "Fistula of the Large Intestines."

HEALTH OFFICE REPORT for week ending Feb. 8, 1896: Deaths under 5 years 32, total 79. Births, male 56; female 54, total 110. Contagious diseases: Diphtheria, last report 21, new cases 6, recovered 19, died 1, now sick 7; scarlet fever, last report 22, new cases 5, recovered 7, died none, now sick 20; smallpox, last report none, new cases 2, recovered none, died none, now sick 2.

Atlanta Notes.

THE RESIDENT MEMBERSHIP OF THE AMERICAN MEDICAL ASSOCIATION here in our city is not near as large as it should be, so that we trust the meeting next May will be able to awaken more interest among the southern physicians and thus add an increased membership from this section of our States. However, Atlanta has always been equal to every emergency, and the medical fraternity of our city will see that the visitors here next May shall be well cared for. The Local Committee of Arrangements have already been selected and are now actively engaged in perfecting all the details relative to the next annual meeting.

THE ATLANTA SOCIETY OF MEDICINE held its annual meeting for the election of officers on the second Tuesday evening in January. The following officers were elected for the ensuing year: President, Dr. R. R. Kime; Vice-President, Dr. W. A. Crowe; Secretary, Dr. W. L. Champion; Corresponding Secretary, Dr. Dunbar Roy.

AT A RECENT MEETING of the Faculty of the Southern Medical College some changes were made in that body on account

of the recent death of the President, Dr. Thomas S. Powell. Dr. Wm. Perrin Nicolson, who was formerly Dean, was elected President, and Dr. Jas. B. Baird, recently elected to the chair of Practice of Medicine, was made Dean. Dr. Dunbar Roy was made Secretary of the Faculty. Dr. W. A. Crowe was elected to fill the chair of Obstetrics for the unexpired term of this session.

DR. C. D. HURT has been elected Visiting Physician to the Grady Hospital in place of Dr. J. S. Todd, resigned.

DR. J. C. OLMSTED has been appointed by the Governor as a member of the "Allopathic" Board of State Medical Examiners, *vice* Dr. Jas. B. Baird, who was made ineligible to that position by accepting a professorship in one of the State medical colleges.

DR. C. M. DRAKE, late of Knoxville, has been appointed Chief Surgeon to the Southern Railway System. Dr. Drake will remove to Atlanta and make this his headquarters since it is the central point of this railway system.

DR. DUNBAR ROY has been appointed Oculist and Aurist, and Dr. W. Jarnagin Local Surgeon to the Southern Road.

Washington Notes.

WEEKLY REPORT OF THE HEALTH DEPARTMENT.—The report of the Health Officer for the week ended February 1 is as follows: Number of deaths (stillbirths not included), white 52, colored 49, total 101; death rate per 1,000 per annum, white 14.4, colored 28.3, total 19.0; death rate per 1,000 per annum for the corresponding week last year, 17.3. A decline of over 9 per cent. took place in the total mortality of the District during the past week. The number of deaths reported at the Health Department was 101 as compared with 112 in the previous week. There were 39 deaths from lung maladies, of which 12 were from consumption and 16 from pneumonia. But one death from typhoid fever was reported and one from scarlet fever. A fall of seven occurred in the mortality among children under 5 years of age. The annual death rate was 19.0 as against 21.1 by the last report and 17.3 for the corresponding week of last year.

RECRUITS TO THE AMBULANCE CORPS.—The Ambulance Corps of the District Guard, at its meeting last week, elected to membership William M. Johnson, Jr., G. V. Stockslayer, W. T. Rawlings, H. D. Miller and W. E. Cook. Since the corps has been under its present command it has taken a new life, and many applications are presented at every meeting.

SIDE ARMS FOR THE HOSPITAL CORPS.—The Secretary of War has ordered that side arms shall not be issued to members of the U. S. Army Hospital Corps, except when they are serving in Indian wars or are left with wounded under circumstances which justify the expectation that their rights as non-combatants will not be recognized.

POLICE AND CONTAGIOUS DISEASES.—The Commissioners have amended the manual of the police department by adding to paragraph 162 of the same the following:

"No member of the police department in whose family there exists a case of diphtheria, scarlet fever or smallpox will be permitted in any way to come in contact with the patient suffering with the disease, or those in attendance upon such patient, except that it shall be shown, upon a certificate of the attending physician, to the satisfaction of the surgeon of the police department in that district, that the presence of such member is imperatively demanded at home, in which event leave of absence shall be issued to him by the surgeon of his district, in accordance with the law governing sickness in the police department. This rule permits members to visit their homes for meals, but for no other purpose. Clothing and other personal effects of a member which have been subjected to infection by the proximity of the patient must undergo thorough disinfection before being again used. When a policeman has been in direct contact with the patient, or in the patient's room, such policeman must be thoroughly cleansed by bath and sponging with some disinfecting solution, to be prescribed by the surgeon of his district, and must robe himself thoroughly throughout in clothing that has not been subjected to infection, or that has been thoroughly disinfected, before he may return to the station house."

MEDICAL PRACTICE BILL REPORTED TO THE HOUSE.—Mr. Babcock has submitted to the House a report on the bill to regulate the practice of medicine and surgery in the District, which was ordered reported by the committee last Wednesday. The report says that the committee finds that in consequence of the enactment of medical practice laws in forty-three States and Territories the District has become a rendezvous for those who, from lack of proper qualifications, are forbidden in nearly all States and Territories, and that a uniform grade of qualification for medical practice will elevate the standard of medical education. The report says there are five medical schools without uniform standard of curriculum or qualification for the degree of doctor of medicine. There are also three medical societies, each authorized to license men to practice medicine in the District, upon the presentation of such diploma as the applicant may offer. Under the existing law five men can obtain a charter authorizing them to confer the degree of doctor of medicine to any person, and a representative of one such institution admitted to the committee that it had no building or provisions of any kind to teach medicine in any of its branches. The report strongly urges the passage of the bill.

THE FORTIETH ANNUAL REPORT OF ST. ELIZABETH'S ASYLUM.—Dr. W. W. Godding has transmitted his annual report of the Government Hospital for the Insane, to the Secretary of the Interior, for the year ending June 30, 1895. It shows that 2,052 patients were under treatment during the hospital year. There remained June 30, 1894, 1,681 patients, and there were admitted during the year 371 patients. Of the whole number under treatment, 1,570 were males, and 482 were females. There were discharged as recovered, 98; as improved, 72; as unimproved, 1, and 179 died, leaving under treatment June 30, 1895, 1,702 patients, 1,318 males and 384 females. Of the 179 deaths at the institution during the year, the principal causes were cardiac valvular disease, of which 18 died; general paralysis, 14; organic disease of the brain, 27; phthisis, 18. The duration of mental disease of those who died ranged from two weeks to forty-four years.

The report shows that 9,586 cases have been treated since the opening of St. Elizabeth Hospital, in 1855. The nativity of these cases treated shows that the District of Columbia leads in the native born with 1,158 cases, and Ireland in the foreign born, with 1,681 cases, followed by 1,155 cases of German birth. The report says: "The number of admissions, 371, an average of more than one a day, has never been exceeded within the hospital history, except during the last two years of the war, while the whole number under treatment, 2,052, is in excess of that of any previous year, and that the daily average number is nearly 50 more than ever before. The recoveries 98, just 28 per cent. of the discharges, makes a favorable showing which the chronic character of the great proportion of cases is taken into account. The deaths were 179, showing a mortality of 10.73 per cent. on the average number, and 8.72 per cent. of the whole number under treatment. Ninety-three of the deaths were of soldiers and sailors."

The report then comments on "the abortive attempts of the United States government to fill the Eastern Branch flats," and says this is the probable cause of more than one-half the sickness occurring at St. Elizabeth.

Of the latest addition to St. Elizabeth's, the large domain below Oxen Hill, and known as Godding Croft, the report says: "The sixth group, the agricultural one, is a colony at Godding Croft for chronic cases; harmless workmen, who, having a home with home comforts, are content. The nucleus of such a colony is already established. At Godding Croft there are sixty acres of the finest garden soil that exists anywhere within the nearly 800 acres of this government ground. Here are 25 acres of hillside, well adapted to vineyards and orchards; 60 acres of corn and grass land, with more than 100 acres of woodland and pasturage. The estimates for the fiscal year ending June 30, 1895, amount in all to \$412,400."

MEDICAL SOCIETY. At the meeting of the Society held on the 5th inst., Dr. Wellington read the essay of the evening, entitled "Castration for Hypertrophy of the Prostate Gland." Dr. Acker reported a case of typhoid fever and presented the specimen. Dr. H. L. E. Johnson reported three successful cases of abdominal section, two for ovarian tumor and one myomectomy. The specimens were presented. The report of the committee on "transactions publication" was read but its

consideration was postponed for one week. The Society unanimously endorsed the House bill to regulate the practice of medicine in the District.

WASHINGTON OBSTETRICAL AND GYNCOLOGICAL SOCIETY.—The 240th meeting of the Society was held on the 7th inst. Dr. Bovee read a paper on "Anterior Colpotomy and reported seven cases. Dr. H. L. E. Johnson reported a successful case of myomectomy. Dr. Stone presented three specimens from operation for pus tubes. The paper and cases brought a lengthy and interesting discussion.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from February 1, 1895, to January 7, 1896.

Capt. William O. Owen, Jr., Asst. Surgeon U. S. A., leave of absence granted on surgeon's certificate of disability is extended one month on account of sickness.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending February 8, 1896.

P. A. Surgeon C. H. T. Lowndes, detached from marine rendezvous, San Francisco, and granted one month's leave.

Asst. Surgeon C. P. Bagge, detached from the "Vermont" and ordered to the marine rendezvous, San Francisco, Cal.

Marine-Hospital Changes. Official list of changes of station, and duties of Medical Officers of the U. S. Marine-Hospital Service, for the sixteen days ended January 31, 1896.

P. A. Surgeon C. E. Banks, to proceed from Washington, D. C., to Boston, Mass., for temporary duty, Jan. 31, 1896.

P. A. Surgeon W. J. Pettus, to assume temporary command of Service at Norfolk, Va., Jan. 31, 1896.

P. A. Surgeon G. M. Guiteras, to proceed from Gulf Quarantine to Mobile, Ala., for temporary duty, Jan. 18, 1896. To rejoin station at Gulf Quarantine, Jan. 31, 1896.

Asst. Surgeon W. J. Stewart, granted leave of absence for ten days, Jan. 27, 1896. Ordered to examination for promotion, Jan. 31, 1896.

Asst. Surgeon E. K. Sprague, granted leave of absence for twenty days, Jan. 23, 1896.

Asst. Surgeon Emil Prochazka, to proceed from Detroit, Mich., to Chicago, Ill., for temporary duty, Jan. 31, 1896.

Asst. Surgeon H. W. Wickes, upon completion of temporary duty at Memphis, Tenn., to return to his station at New Orleans, La., Jan. 17, 1896.

BOARD CONVENED.

Board convened to meet in New York City for the physical examination of a candidate for appointment in revenue cutter service, Surgeon W. A. Wheeler, chairman, and Asst. Surgeon H. S. Cumming, recorder, Jan. 29, 1896.

Change of Address.

Coolidge, F. S., from 2207 Prairie Ave., to 2632 Prairie Ave., Chicago, Ill.

Gihon, A. L., from 16 W. 31st St. to 8 W. 127th St., New York, N. Y.

Minar, E. G., from Bay City, Mich., to Mannsville, Jefferson Co., N. Y.

Price, M. F., from Los Angeles to Indio, Riverside Co., Cal.

Tillier, F., from St. Paul to Blue Earth City, Minn.

LETTERS RECEIVED.

No. 8.

ADDRESS.

PRESIDENT'S ADDRESS.

Delivered at the Second Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 25-27, 1895.

BY C. K. COLE, M.D.

CHIEF SURGEON MONTANA CENTRAL RAILWAY.
HELENA, MONT.

Fellows of the American Academy of Railway Surgeons:—I congratulate you, and through you the railway hospital service of the country, upon the evidences of success and prosperity attained by your association in the short space of one year. A year ago the need of such an association as this Academy was by many doubted, by a few urgently denied, and by those few the proposition to effect an organization was violently opposed. For the most part it is fair to assume that the opposition, whether merely passive or as in certain instances quite active, reflected the honest sentiments of those who were equally desirous in the interests of railway surgery, as were those of us who felt the time ripe for the consummation of what had long been considered desirable, if not an actual necessity. No stronger justification of the wisdom of the undertaking and no better vindication of the motives which prompted the promoters, could be desired, than the events which have transpired touching the interests of the Academy during the past eighteen months, and I may add no greater inspiration is needed to a continuation of honest, loyal work in the future along the lines governing this association than a glance at the splendid scientific program for this meeting, and the additional fact that 85 per cent. of the Fellows of the Academy are present to participate in our proceedings.

Gentlemen, while these are matters for congratulation, and calculated to stir us with enthusiasm in behalf of our organization, let us not take a narrow conception of our work, which, as Fellows of the Academy, is necessarily national in its character. Let us rather seek by individual effort to promote a proper spirit of competition, remembering that as individuals and also as a society we will be carefully and accurately judged by public opinion, as well as by our own consciences, than which no higher or more impartial court ever found a verdict.

In this era of verbosity in medical literature it is often extremely difficult even with those of large experience, as well as extensive personal acquaintance, to select the really good from that which is mediocre in what is written. An important function of this Academy is to seek to establish a standard in the literature of railway surgery in America. I undertake to say that if each gentleman in affiliation with the Academy would give the same painstaking attention to what he writes for publication as he does to his ordinary professional duties, never lending himself to the popular idea of writing frequent lengthy and often empty arti-

cles for print, the literature of the Academy would in a few years be recognized as trustworthy and authoritative in matters pertaining to railway surgery, and its Fellows would be credited with having established an institution worthy of commemoration. The erstwhile mooted question as to establishing railway surgery as a specialty requiring special aptitude, special training and special facilities for work, is rapidly being settled, and it is safe to predict that in the near future, railway surgery as a specialty will be firmly established in the minds of not only the medical profession generally, but of also those distinguished laymen who have to do with the building and management of our great railways. Specialism in railway surgery does not consist in the use of certain apparatus, instruments, dressings, etc., nor does it consist in the possession of any peculiar technical knowledge not necessary to the general surgeon, for we are all governed by well-established surgical laws, and the application of certain cardinal principles is the same, whether in railway, military or other emergency surgery. It can not, however, be denied that in matters of organization and equipment, including transportation of patients, and many other details peculiar to railway surgery, special qualifications are essential to the best success. The general or chief surgeon of a road must have certain mental characteristics, not the least important of which is executive ability of a high order, together with a judicial instinct which will enable him under all circumstances to be fair and impartial to all concerned. He must, moreover, command the respect and confidence of his *confidères* generally and especially of his local surgeons, many of whom will be found to be his superior in point of operative ability, and each of whom should be a reputable practitioner in the best sense of the term.

I trust I may be forgiven the apparent, if not the real egotism of assuming to inflict so much parental advice, and beg in extenuation to say that the impulse is born of a deep feeling of interest in the present and future welfare of this association. We are making history, and it depends upon ourselves whether the future shall reveal the wisdom or unwisdom of our actions. This Academy is no longer an experiment with an uncertain future but an assured fact, and if we carefully observe the tenets of our organization there can be no doubt as to the ultimate result of our labors.

Generally speaking, the medical press throughout the country have been kind and courteous to us. The same may be said of the management of our various railways, which have almost without exception commended the general scheme of our organization, and especially the distinctive features of a strictly limited membership, with rigid scrutiny as to the qualification and standing of every applicant for fellowship.

I desire to express thanks to my associates in office especially, and to each of you for the very efficient

service rendered during the past year. For myself, the honor of having served as your first President is sufficient recompense for whatever effort the filling the position has cost.

ORIGINAL ARTICLES.

WHAT SHOULD EXCLUDE APPLICANTS FROM RAILWAY SERVICE?

Read at the Second Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 25-27, 1895.

BY JOHN E. OWENS, M.D.

Chief Surgeon Chicago and Northwestern and Illinois Central Railways.

CHICAGO, ILL.

It is a matter of practical interest to determine what should and what should not exclude applicants from railway service.

The formulation of any set of rules intended to govern examinations presupposes the adoption of a working basis, and the classification of the applicants for service.

So far as disabling diseases are concerned, it will not be necessary to mention those which are so disabling as to discourage the sufferer from following any pursuit. Others, again, are more or less insidious in their progress and for a time do not furnish symptoms which make the patient aware of their existence. Certain conditions interfere with the healing of wounds, impede recovery, entail an undue loss of time, and become aggravated by the injuries which are received in the line of duty. It would be useless to enumerate all the diseases which would disable the applicant. From a medical standpoint the following will perhaps be sufficient to turn the attention of the medical examiners in the right direction: Diabetes, cancer in all its forms and in all localities, chronic diarrhea, the presence of gallstones, chronic inflammations, hemoptysis, tuberculosis, asthma, organic cardiac disease, evidences of organic disease of the brain and its meninges and of the spinal cord.

From a surgical standpoint the following should exclude the applicant from service: Necrosis, ulcerations in any region, scrofula, bubo, malignant tumors, phlebitis, varicose veins, aneurysm, acute and chronic periostitis, synovitis, arthritis, floating cartilages, old depressed fractures of the skull, or any fracture followed by head symptoms, suppurative ear diseases, antero-posterior spinal curvature, severe injuries of the back, recurring appendicitis, abdominal hernias, acute and chronic cystitis, acute gonorrhea, epididymitis, enlarged testicle, certain visual defects and deafness.

INSTRUCTIONS GOVERNING SURGEONS IN CONDUCTING EXAMINATIONS OF APPLICANTS FOR EMPLOYMENT ON RAILROADS.

When making application for service, engineers, firemen, agents, operators, conductors, brakemen, engine dispatchers, train baggagemen, station baggagemen, crossing flagmen, switchmen, switch tenders and signalmen must be examined for color perception, hearing, and for visual and other physical defects.

Examining surgeons are requested to select a time and place at which they will conduct examinations, and to notify the proper officer.

Examinations are to be conducted in a well-lighted room at least twenty-two feet in length. In testing visual acuteness, only one applicant should be present

in the room at a time. In testing color perception and hearing, any number of applicants may be present, but must maintain silence.

Examining surgeons are provided with the following articles to be used in making examinations:

1. Two cards of test type (Snellen's). (One for illiterates.)

2. A set of wools for testing color perception.

Applicants will bring with them application forms *in duplicate* on which will be found a blank certificate, to be filled out and signed by the examining surgeon.

EXAMINATIONS IN VISUAL ACUTENESS.

The card of test types should be fastened in a good light to a wall, the bottom of a card being about five feet from the floor.

A distance of twenty feet should then be measured off on the floor at a right angle to the plane of the card. Applicants are then to be admitted singly and instructed to read the card from above downward without assistance. In cases of defective vision, after testing vision for both eyes, each eye should be tested separately. The last five letters read correctly are to be recorded in the report.

Examiners are reminded that the normal-eyed should read at twenty feet the line marked 6 m.

EXAMINATION IN COLOR PERCEPTION.

Examiners are furnished with a set of colored wools, lettered A, B, and C, and numbered from 1 to 40. These wools are divided into three groups, distinguished as follows:

Group A, containing the light green skein A, the green shades numbered 2, 4, 6, 8, 10, 12, 14, 16, 18 and 20, and the gray confusion colors numbered 1, 3, 5, 7, 9, 11, 13, 15, 17 and 19.

Group B, containing the pink or purple skein B, the pink or purple shades numbered 22, 24, 26, 28 and 30, and the blue confusion colors numbered 21, 23, 25, 27 and 29.

Group C, containing the red skein C, the red shades numbered 32, 34, 36, 38 and 40, and the brown confusion colors numbered 31, 33, 35, 37 and 39.

MANNER OF USING THE WOOLS.

Mix the forty skeins thoroughly and throw them on a table in a good light; select skein A, and, placing it about twelve inches distant from the pile of wools, instruct the applicant to pick out the different shades of the same color.

The examiner, having satisfied himself of the ability or inability of the applicant to select the proper skeins, should record the numbers of the skeins selected and return them to the pile. The examiner should then place the skeins B and C successively near the pile of wools, to be treated in the same manner.

In testing for defects in color perception, examining surgeons may be guided by the following brief suggestions:

1. Any number of applicants may watch the test in operation, provided they maintain silence. In case an applicant fails to comprehend the test, he may be directed to step aside and watch another applicant select the skeins, or in the absence of another applicant the surgeon may himself make the selection. This method is valuable in case of color blindness, as the applicant is convinced against his will that the test is a fair one.

2. Do not under any circumstances call the color of a skein. All tests in which the applicant is requested

to name colors or shades are incorrect. The object of the test is to discover whether the applicant can properly classify shades of primary colors, and it is important after he thoroughly understands what is expected of him not to render him any assistance.

3. It is well, if necessary, to explain the difference between colors and shades, for example: Blue, green, red, are colors. Light blue, dark blue, pea green, Venetian red, are shades of these colors.

The examiner should watch the applicant closely and note any hesitancy in selecting the skeins, especially when he appears undecided whether or not to select a confusion color. Should he evince a strong tendency to select any confusion color, even if he does not actually select it, the number of the color should be recorded. Those who are defective in color sense, either select the confusion colors or want to do so.

4. Recollect, however, that blue is not a confusion color for green but only for pink (purple). It must be borne in mind that many men, not particularly ignorant in other matters, find it difficult to distinguish between light shades of blue and green, or between red and orange. This defect is one merely of education. It is the result of color ignorance, but not of color blindness, and should not reject a candidate. In case such ignorance is manifested, it may be well to call the applicant's attention to the fact that he is not well posted in colors.

5. In case of color blindness, the applicant usually adopts one of two courses. He may boldly and rapidly select a number of skeins at random, throwing them down with a great show of confidence, or he will laboriously study over the skeins, carefully selecting a few of the correct colors, and a few—often not more than one—of the confusion colors, always hesitating and usually selecting shades of nearly the same intensity in color and confusion of colors, for example: light green, light gray, light purple and light blue.

The infirmity of applicants adopting the first course is usually easy to detect, but it is often difficult to distinguish between a man who is hesitating and vacillating on account of lack of purpose or color ignorance, and one who does so on account of actual deficiency in color perception. In these latter cases it is well to instruct the applicant not to handle the wool until he has determined what skein he wishes to select. The applicant may also be permitted to watch another while making the test.

6. In case more than one applicant is present during the examination the wools should be frequently mixed, and other applicants should stand far enough from the table to be unable to read the numbers on the skeins, or the skeins may be arranged with the numbers turned down.

Inasmuch as the duties for the different railway employes are widely different, the requirements for efficient service would likewise vary. It would therefore be judicious to formulate the following classification:

In the first class, or those with normal hearing, color sense and visual power, are included the following: Engineers, firemen, engine dispatchers, brakemen, signalmen, conductors and train baggagemen.

In the second class, in which normal color sense and normal hearing are demanded, and also perfect visual power in one eye, while the other might attain to only 20-40 of the standard, or 20-30 visual power in both eyes, or both of which may be made so by the use of glasses, are included switchmen, switch

tenders, agents, operators, station baggagemen and crossing flagmen, or gatemen.

PHYSICAL DEFECTS.

1. Applicants with trachoma or other inflammatory conditions of the eyes, or with chronic discharges from the ear, are disqualified.

2. Hernia, varicose veins of both legs, or very marked varicosity of veins in one leg, phlebitis, skin diseases—especially eczema, or even a strong tendency to it, loss of entire thumb or loss of two fingers of one hand, disqualify the first class, and station baggagemen, switchmen and switch tenders in the second class, while crossing flagmen, agents and operators may be accepted with hernia and also with loss of thumb or loss of two or more fingers of one hand.

3. Unmistakable evidence of chronic alcoholism disqualifies both classes.

4. Acute gonorrhea and the primary and secondary manifestations of syphilis, traumatic and pathologic bubo, disqualify both classes as long as the symptoms are apparent.

5. Orchitis, epididymitis, malignant tumors, recurring appendicitis, old depressed fractures of the skull, or any fracture followed by head symptoms; spinal injuries, epilepsy, antero-posterior curvature, severe injuries of the back, tuberculosis, marked scrofulous cachexia, aneurysm, necrosis, acute and chronic periostitis, acute and chronic cystitis, disqualify both classes. Agents, operators and crossing flagmen may be accepted with antero-posterior curvature without symptoms.

6. While synovitis, arthritis, floating cartilages and impaired mobility of joints disqualify the first class, and switchmen, switch tenders and station baggagemen in the second class, the latter need not exclude agents and operators, provided inflammation has long since subsided and the affected joints be free from pain.

7. From a medical standpoint, diabetes, chronic rheumatism and gout, chronic diarrhea, chronic hepatic disorders attended with jaundice, are disabling in their nature; hepatic, cardiac or renal dropsies, asthma, hemoptysis, valvular disease of the heart, angina pectoris, evidences of organic disease of brain or spinal cord, insolation, inveterate neuralgia of the larger nerves, disqualify both classes, while crossing flagmen may be accepted with a moderate amount of chronic rheumatism.

8. Under the head of disqualifying defects, surgeons will be careful to note any physical defects that would impair the usefulness of the applicant, that would be more or less aggravated by the service, or would contribute to the prolongation of disability in case of injury.

9. In order to prevent fraud in subsequent claims for personal injury, a careful record must be made in the proper place of physical defects which do not impair the usefulness of the applicant, that would not be aggravated by the service, or would not contribute to the prolongation of disability in case of injury.

10. In case the applicant does not show evidence of having been vaccinated since attaining to adult years, he should be vaccinated.

After making the test of vision, color perception, hearing and examination for physical defects, the examination surgeon will fill out and sign in duplicate the blank certificate found on the application blanks.

One of these is sent to the Division Superintendent or Master Mechanic, and the other to the Chief Surgeon. The fee for making such examination will be paid by the company unless the applicant is accepted as an employé, in which case the amount of the fee is deducted from his wages. The certificate referred to is as follows:

SURGEON'S CERTIFICATE.

(Here follows a list of stations where examinations may be made.)

The following is the report of the result of my examination of Mr.

1. When placed at a distance of twenty feet from the test types, the last five letters read correctly by the applicant are: Right eye. : left eye. : both eyes.

2. A. The applicant selects skeins numbered as follows, as being the same color as test skein A: B. The following as being of the same color as test skein B: C. The following as being of the same color as test skein C:

3. The applicant hears the tick of a watch with the right ear at inches: with the left ear at inches. For ordinary conversation at a distance of twenty feet, the hearing is impaired.

I hereby certify that, having examined the visual power, color perception and sense of hearing of the applicant, I find him $\left\{ \begin{array}{l} \text{qualified} \\ \text{disqualified} \end{array} \right\}$ to fill the position of

I also certify that there is evidence of his having been successfully vaccinated, that he is not suffering from any disease or disability, nor does he manifest any evidence of an abuse of intoxicating liquors.

Disqualifying defects : defects that do not disqualify (Signed.) Surgeon.
Dated at 189

In presenting this paper, my desire is to formulate a tentative working basis for the purpose named. In all probability its practical working will suggest useful changes, and I am glad to avail myself of this opportunity for conference with the able Fellows here present, and hope that they will make important suggestions.

DISCUSSION.

DR. WEBB J. KELLY. I was very much interested in the paper of Dr. Owens, probably on account of the fact that in Ohio the railways have to a certain extent evaded the law. The law compels them to have the test for color blindness made, and it has been the custom of some roads—I will not say all—to select some one of the trainmasters to make the examination. The doctor in his paper calls attention to one point that impressed me very much, and I think the management of railways should have their attention called to it, namely, not designating what color they are to select as a color, giving it the name. As the doctor says, the test color is placed on the table and then the parties to be examined are asked to select the colors that match it. I have known instances that have come up on one of the roads I represent in which an employé would be examined for color blindness, and he would be asked to pick out all the greens in the bunch, and in that way the examiner would get the man confused. Were he to take the original green and ask the man to match it, I have no doubt the man would have done it correctly. I think this an important point in the doctor's paper to which we should call the attention of the management of our roads where they do not have a regularly employed surgeon to make these examinations.

DR. F. K. AINSWORTH. There is very much to commend in the paper of Dr. Owens and very little to criticise. I would ask the doctor what he does in the case of crippled employes? For instance, a man is employed in some branch of the railway service who has not had an examination for color perception, etc., who has lost a leg or some other member, and the company is anxious to do something for him—what can be done in such case? Under the rules of Dr. Owens that man could not become a flagman. It is becoming a question what to do with

the crippled employes of our railroads. We have filled the positions of flagmen with these men, or in some cases with old engineers who are unable to do anything else.

In regard to the test for color perception, the doctor's rules are the same practically as ours, and I will only speak of one point that seems of great value. I have many times had men fail in the color test when made by the worsteds. Of course, in many instances I believe it was due largely to ignorance of colors, while in others it was attributable in greater or less degree to color blindness. These men, if given low surface flags, can pick them out every time without making any errors. They can pick them out in a dark room. If a man recognizes smoky lights without error, I should think it would be safe enough to put him on duty even if he had failed in distinguishing the wools.

DR. D. S. FAIRCHILD.—Beginning with this month I have examined two hundred men under the regulations which have been adopted by Dr. Owens, and I have been astonished at the number of men who could not come up to the standard. Out of fifty-one men examined, twenty-four of them had either defective vision, defective hearing, or had large abdominal rings. Now, I have been making a note of all those cases in which there were large addominal rings. While these men are not disqualified, as far as the railway service is concerned, it is quite possible that some time in the future difficulty will develop. It not infrequently happens that an injured man, either a switchman or brakeman, comes into our office and says he was hurt in consequence of trying to climb on a moving train. The round of the ladder gave way, he fell, and hernia followed. Now, it is quite possible that such a man had weak abdominal walls previous to this time, that the hernial rings were large, and that in consequence hernia was developed and the railway company has to pay for an injury which they ought not to pay for. I do not know what regulations Dr. Owens makes in regard to the acceptance of candidates who have such abdominal rings. To my mind, in a certain sense it would be disqualifying evidence. I have observed that men over 30 years of age, in a large percentage of the cases examined, had defective vision, and that 20-30 was about as far as they could see with both eyes. I find also in a number of instances that vision in one eye would be 20-30 or 20-40, or in both eyes 20-20.

In regard to the color test, I have observed a good deal of ignorance on this subject, and if the applicants were required to name the colors there would be many that would be considered color blind. To mention color does away with the element of ignorance. The candidate on being asked to select the skeins at once says he has been engaged in the kind of work that enables him to learn different colors. Not a few clerks in a drygoods store fail in naming certain colors. He has to simply select two colors and all shades of those colors, and in this way he is able to determine what belongs to the reds and the greens and avoid putting in any combination colors with them. Out of fifty-one cases examined, I found one candidate color blind, and one with a fully developed direct inguinal hernia with an extremely large external ring on either side, which would permit of the introduction of two fingers. I found one case of mitral insufficiency with compensatory hypertrophy. In this case the condition would not disqualify him for employment now, but of course the compensatory hypertrophy would be against him sooner or later. On our road the superintendent is required to have all applicants undergo this examination. When the slack time came last year and year before, instead of laying these men off for a period of time, they were discharged, but were obliged to seek re-employment under the same rules that new or recent applicants would have to observe. These men have all been examined, and I think it is the intention of our superintendent, so far as he has jurisdiction over the matter, not to employ any men over 30 years of age unless they come up to a high standard, and as previously stated, I have

observed that those men who are over 30 years of age have some defect of vision.

There is another point in regard to hearing. We find men in the engineering department—I mean the locomotive engineering department—employed as either firemen or otherwise, in the machine shops, who have defective hearing so far as the watch is concerned. In some cases they can hear a watch tick only eight or ten inches, in one case I recall only four inches, and in another the man could only hear the watch tick two inches distant from one ear, and not at all with the other ear; yet the hearing at a distance did not seem to be materially defective. I requested this last candidate to have a specialist examine his ears and determine whether or not there was any disease of the organ. The aurist returned a written report saying that there was no disease of the ear, and that the watch test was not a fair one in this case; that he could hear easily at a distance of twenty feet, whereas he could not hear the watch at all with one ear, and with the other only a distance of two inches. The opportunity of making these examinations has revealed to me a risk which railway companies have taken heretofore in employing men in this capacity, so far as their physical condition of hearing and seeing is concerned.

DR. OWENS (closing the discussion)—This matter of examining applicants for the railway service is an exceedingly important one, and I might say that an examiner is not made in a day. When I first took the matter up, it took me some three months to investigate it, before I felt justified in doing this important work. Now, we have examiners on our roads who do not really know how to examine these men. Perhaps I ought to be ashamed to say it. I know they will be able to do it after a while. The reports come to me and I pass on them. If there is anything wrong we rectify it in some way. How can we get our examiners to thoroughly examine these applicants? In the first place the matter must be thoroughly studied. I have recently come in contact with the report of a committee of the Royal Society of London on this subject. It takes the subject up in all its relations, criticising the methods of the Board of Trade which seem to be so very defective that they were not accepted at all. It is one of the most valuable pamphlets on the subject that I know of. Then there is a book just issued, the "Dalton Lectures," which treats of the subject of color blindness. There are various text-books on diseases of the eye that one may pick up, but they do not go into the subject of color blindness to a sufficient extent to enable the examiner to do his work well. I intend to get a number of these reports and will have the surgeons connected with our roads procure them through us.

It is said that applicants who have made some mistakes with worsteds are able to name the colors of the flags and the lanterns correctly. The question is whether a man who makes mistakes with worsteds and does not in the case of flags and lanterns should be accepted. That throws into the examination the naming of colors which is a defective method. On the Illinois Central Road the examinations were made first with worsteds, and then Mr. Jeffrey ordered that the examinations be repeated, and the applicants were examined with flags and lamps. I was timid as to the efficiency of the latter method. My assistant, Dr. Allport, of the Illinois Central Road, has examined many applicants with flags and lanterns, as well as with worsteds. The conclusion has been reached that men who are color blind with worsteds will make mistakes with flags and lanterns.

Forty Thousand Acres of Land for Insane Asylum.—One of the acts of the South Dakota Legislature in 1895 was to appropriate and set apart for the use and benefit of the Northern Hospital for the insane, forty thousand acres of the land granted to that State for "other educational and charitable purposes."

APPENDICITIS; PROTEAN TYPES.

Read before Jackson County Medical Society at Kansas City, Aug. 22, 1895.

BY A. H. CORDIER, M.D.

Lecturer on Abdominal Surgery Kansas City Medical College; Vice-President American Association of Obstetricians and Gynecologists.
KANSAS CITY, MO.

To the members of the Jackson County Medical Society a paper on appendicitis may, on first thought, seem a trite topic for discussion, yet when the many phases of this treacherous disease are called to mind we at once realize that it is a topic the importance of which demands oft repeated discussions, that a more unanimous opinion of the pathology of the disease may be obtained, and its proper treatment better understood. In the face of our more advanced and modern pathologic knowledge we yet have conscientious practitioners who claim that they have never seen a case of appendicitis, and another class also exists, that admit having cases, but claim the ability to cure them, denying the probability of a death from the disease. A still more liberal class may be found that is willing to meet the surgeon halfway and become associated with him in the case, waiting and watching for the so-called operation indications to spring up. It is just this delay, too often, that results in the signing of a death certificate. A few days ago a very intelligent, thoughtful professional gentleman (a minister) met me on the street, and referring to a late case of appendicitis upon which I operated said, "I am glad to hear that one case of appendicitis has recovered after an operation." It has crept into the minds of not only the laymen but of the profession, in many instances, that the mortality from this operation is high. This deduction is in part correct, but thanks to the converting evidence of the post-mortem and operating tables the deaths from delayed surgery are of less frequent occurrence than formerly. If any one disbelieves in the advisability of operating in appendicitis in almost every case, he will quickly change his views if present at a number of operations, or if he witnesses a few post-mortems on patients dead from the disease. I do not believe that every patient with a pain in the region of the appendix should be subjected to laparotomy, but I do think that when the diagnosis of appendicitis has been made, if every case was operated upon by a skilled surgeon, the mortality from the operation and the disease would be almost *nil*. A great and dangerous mistake is often made in waiting for the operation indications, as they are usually called, to spring up in these cases. Every case of appendicitis is symptomatically an individual, and the surgeon or physician who looks for a stereotyped case will hunt a long time before the case will be found that exactly tallies in its manifestations with a book description. A large and varied experience engenders the best judgment in correctly interpreting the manifestations of the protean types of this pathology; not only experience in seeing the cases from a practitioner's point of view, but from the surgical and pathologic.

A bright but decidedly conservative practitioner once told me, as I was making preparations to operate on an appendicular abscess, that if the subject was his child he should not be operated on, but after witnessing an operation that revealed a large amount of stinking pus, and a gangrenous appendix, he at once turned over a new leaf, and I have since operated upon three cases for him, with success in all four cases.

In the catarrhal form of the disease a symptomatic transient lull is often noticed, but sooner or later a recurrence of greater or less severity supervenes, and the sufferings and dangers incident to a relapse are repeated. In this form of the disease the mucous membrane of the appendix is primarily influenced, the subsequent attack invading more and more deeply the muscular and other structures of the appendix, thickening its walls, cutting off the proper blood supply by these interstitial infiltrations, obstructing the proximal end of the canal at Gerlach's valve, and inducing an extra amount of secretion into the distal portion; this in turn becomes infected usually with the bacterium coli, and a simple catarrhal change is converted into a septic purulent one, to be followed by local (perforation) or general (gangrene) death of the organ. It has been the exception, not the rule, that I have found a foreign body in the appendix. In one case I found an orange seed, in another a peanut kernel, and in another a piece of chewing gum.

This inflammatory change is prone to attack the subserous tissue and lead to an abundance of exudation, the first step nature takes to protect the general peritoneum. This inflammatory edema extends to the surrounding peritoneum, agglutinates the surfaces, and thus adhesions are formed, nature's barrier. If there is only one attack, and if that spell stops short of suppuration, the veil-like adhesions are absorbed. If the case was a catarrhal one the changed walls of the appendix approach the normal again, and the appendix may get entirely well, or more likely be ignited at some future time, or number of times, ultimately proving fatal.

A fecal concretion is often the cause of a perforation or gangrene of the appendix. The inflammatory forerunners are protective processes and are not of a truly septic character in the initial stage, and it is to this fact that we must attribute the prophylactic building of these barriers. A truly septic peritonitis rapidly spreading is not preceded by these limiting sentinels, consequently is rarely limited. A perforated appendix, liberating large quantities of septic matter into the peritoneal cavity, unless removed quickly, and followed by the most careful toilet, inaugurates a fatal form of peritonitis. They die, if not saved by surgery, as quickly as by a perforated gunshot injury to the intestines.

In a case of appendicitis, primary or recurrent, can we tell whether a perforation is going to take place or not? I say no. Can a large per cent. of the cases be looked upon as dangerous from the time a diagnosis is made? Yes. Have we a remedy in the list of drugs for which any one has claimed that it will prevent or cure an appendicitis when once developed? No. Is the mortality from the operation, when done timely, high? No. In what class of cases of appendicitis is the mortality following an operation highest? In cases where hot stupes and large doses of morphia have been used, and delays countenanced. Is the operation safe and easy for any one to perform? No. I know of no operation in the domain of abdominal surgery that requires more surgical skill and knowledge than that of appendicectomy. When to stop in the operation, and when to go ahead, are problems of grave import confronting the surgeon in the midst of an operation. Upon his decision depends the life or death of his patient. It is not an operation that is safe to place in the hands of the novice. It is very essential here to know what not to do, as well as to

know what should be done. After an individual has had one or more attacks, and is seemingly well, has he any assurance that he is not going to have another one, or that the next attack will not prove fatal? No.

Case 1.—Appendicular abscess; rupture into cecum; recovery. J. M. L., male, age 45, was taken sick with uneasiness and pain in right iliac fossa, diarrhea, temperature ranging from 99.5 to 102 F. Pulse 80 to 120. After the beginning of the attack he drifted along about as above for ten days, all the time having more or less tenderness and pain in region of appendix. A week after the beginning of the attack an induration developed over or about the cecum, not very painful on pressure. Some two weeks had elapsed when he felt a "giving away" in the mass and a few hours later passed pus and blood per rectum. The mass soon disappeared, and he is to-day up and about, attending to his professional duties.

It would be extremely illogical to reason that as this case made a symptomatic recovery others, seemingly similar, would do likewise. This case was undoubtedly due to the presence of a tubercular ulcer in the appendix, as its slow progress, abundant plastic protective barrier and the history before and afterward indicates. A diarrhea had preceded the case for months. A daughter had died of tubercular peritonitis and ulceration of the intestines, and another child had developed tubercular synovitis. This case should have been operated on early in its progress, and not been permitted to run the gauntlet of dangers incident to procrastination while waiting for nature to relieve herself. Nature is a poor physician or surgeon in appendicitis.

Case 2.—Appendicitis; one mild attack; recovery. Miss L., age 16, was taken with uneasiness over appendix accompanied with some little rise of temperature, 95.5 F., normal pulse, obstinate constipation lasting ten days, no symptoms of intestinal obstruction. All forms of cathartics and enemas given with no response: no vomiting or nausea; general condition of patient all through attack good; no induration, and very little tenderness at any time. This case was watched by myself and the attending physician right along until bowels moved well and symptoms disappeared. I contended all through the case that it was not an appendicitis, but an impaction of cecum, and advised against operative procedure. The attendant claimed that it was an attack of appendicitis, thinks so still, and has reported the case as one cured with medicines. The patient has remained well.

Women do not have the disease as frequently as men (one to six). The obstinate constipation, absence of tympanitis, the complete subsidence of the symptoms following bowel movement, and the non-recurrence of the attack, in my mind warrants me in yet maintaining that she did not have an attack of appendicitis. Let us admit that she did, and has permanently recovered, it only serves to establish the rule by being an exception.

Case 3. Recurring appendicitis; operation in the interval of attack; recovery. H. E., age 20, male, was first attacked with severe pain in region of appendix one year ago, since which time he has had thirteen attacks, each lasting from three to eight days. The attacks have been accompanied by constipation and great distension, the latter often preceding the painful exacerbations a day or two, the tender area usually extending over a space the size of the hand but not as painful on pressure as that usually accompanying a true localized peritonitis. There has not at any time been a localized induration of the surrounding or overlying structures. The attacks have usually been marked by a slight rise of temperature (100 F.), the pulse being very slightly increased in frequency. A disposition to flex the thigh upon the abdomen during the attacks, has been a marked feature in his case, and is explained by the recognition of the fact that the psoas and iliacus muscles are relaxed while the thigh is thus passively flexed upon the abdomen. Any disturbance of these muscles causes more or less movement of the inflamed appendix through its mesenteric attachments, thus giving rise to the increased pain. The genito-crural, anterior crural and ilio-inguinal nerves being immediately (in part of their course) beneath the peritoneum, were more or less disturbed in this case, as manifested by the referred pains in the course of their distri-

bution. During the acute attacks he has been treated by as many as six physicians, in three States. Some of the six are probably reporting this as a cured case of appendicitis without surgery. The attacks were so severe that he would barely throw off the effects of one until another exacerbation would supervene. The appendix could easily be rolled under the finger before operating. Operation July 3, 1895. The appendix was found to be greatly thickened and indurated as a sequela of the repeated attacks of inflammation. Its walls were one-fourth of an inch thick. The operation was performed in the interval of the attacks. His recovery was perfect.

This is one of the most dangerous forms of the disease, as the repeated attacks bring about vascular and other structural changes that favor the death of the appendix (gangrene) and that, too, with no walling in by the protective surrounding adhesions.

Case 4.—Appendicitis obliterans, followed by symptoms of intestinal obstruction. H. G., male, age 28, nine years ago had an attack of what he called inflammation of the bowels, and his right side "caked" and was extremely tender. He had a high fever, and was very sick for a number of weeks. This soreness and pain continued with varying intensity up to the next attack, one year later. This is a diagnostic feature of this form of appendicitis; that is, the soreness and tenderness persist in the interval of the attacks. This second attack was very much the same as the first, lasting three weeks. After this relapse he had fairly good health for four years, with the exception that there was always uneasiness in the region of the appendix and many attacks of what he called "colic" and indigestion, often having to resort to cathartics to keep the bowels regular. At the end of this four-year freedom from severe attacks another "spell" was initiated by severe pain in the region of the appendix and "back ache." Had fever, increased pain and tenderness, lasting two weeks, leaving him seemingly in about the same condition as before. He was often troubled with gas pains and distention, and had "colic spells." He had several mild attacks between the last severe attack and last June, or four years after last severe spell. In June he came down with a severe attack very much like previous paroxysms except that the tenderness was less, no tumor was discoverable and that he had much more gaseous distention and difficulty in getting his bowels to move. Soon after this sickness I saw him, and advised an operation.

I found the appendix atrophied, and its canal completely occluded (appendicitis obliterans). Length of appendix about one and one-half inches. It rolled under the finger like a tendon or a fibrous cord. An inflammatory band the size of the finger was attached to abdominal parietes near internal ring and crossed a coil of bowel and attached itself to the mesentery, thus making a partial intestinal obstruction. This was divided and the appendix removed. He left the hospital in two weeks, and has been entirely relieved of all his painful symptoms.

We have in this case one of the best appeals for an operation in all similar attacks in view of the prolonged suffering and dangers incident to these repeated attacks, and the damage wrought by the delays. Each attack that this man had, endangered his life far more than an operation in skilled hands, having in view a permanent cure and relief for his sufferings.

Case 5.—Appendicitis; gangrene of the appendix; operation; recovery. A. K., male, age 20, was taken on a Saturday night with pain and uneasiness in right iliac region, the pain extending down the inner side of the thigh and in the course of the distribution of the external cutaneous and genito-crural nerves. Very little elevation of temperature (99.5); pulse 84. Hypodermics of morphia were given by the attending physician. The pain and his general condition remained about the same up to Monday afternoon, when I saw him for the first time. Pulse 92 full and "vicious." Temperature 100.5 degrees F. Bright and cheerful except when pains would come on caused by any peristalsis of bowel or movements of thigh. Bowels acted during the night. Tenderness over area size of hand and a false sense of induration over appendix due to rigidity of the abdominal muscles. This condition is often misleading, and added to the edema that frequently attains may be easily mistaken for a walled-off intraperitoneal mass or abscess. At the operation the appendix was found to be gangrenous and entirely free from surrounding protective barriers. His recovery was complete.

Without an operation his blood-vessels would have

been filled with embalmer's fluid within thirty-six hours. An appendix with no walling off, when gangrenous or perforated, kills quickly unless the surgery is immediate.

Case 6.—Appendicitis, recurring, with symptoms of bowel obstruction due to adherent appendix; operation; recovery. Mr. N., aged 44, has had a number of attacks lasting from a few weeks to two months. After last attack, six months ago, he has repeated colic spells, accompanied by obstinate constipation. The cecum would become enormously distended with gas, resembling, as he described it, a croquet ball in size. Operation revealed the appendix long and hard to the touch (appendicitis obliterans in its early stage). The distal end was firmly attached to the iliac vessels. It was ligated near the cecum and again near its distal extremity and removed. The position of the appendix was such that it was pulled upon when the cecum became distended and added to the cause of the symptom producing attacks simulating bowel obstruction. His recovery was complete. He has had no return of his old painful attacks.

Case 7.—Appendicular abscess; operation; recovery. W. K., male, aged 19, was taken down one week before I saw him with fever 102. Pulse 80 to 96. Pain and tenderness gradually getting more severe: constipated bowel, tympanitic; well marked induration in region of appendix. Operation consisted in simply opening the abscess, packing with gauze and leaving wound open to granulate from bottom. Recovery in a few weeks.

This case was one in which nature had time to wall off the appendix before it perforated, but the barrier sooner or later would have been torn down and a death from peritonitis recorded.

Case 8.—Perforative appendicitis; immediate operation; recovery. Mr. Wilson, aged 22. This man, stout and healthy was taken with most intense pain in iliac fossa, accompanied by a subnormal temperature (shock) but with a pulse of only 90. Abdomen distended. A diagnosis of perforative appendicitis was made and operation performed within two hours of the development of the symptoms of perforation. He had been having an "uneasiness there for three days." A septic peritonitis was already inaugurated, but a thorough irrigation with a normal saline solution and gauze and rubber drainage saved him.

Case 9.—Perforated appendicitis followed by a diffused septic peritonitis; operation two days later; death. Miss H., age 16. A lovely young girl, had been complaining for a week, with pain or uneasiness in the region of the appendix. Constipation; little elevation of temperature. Two days before I saw her a most intense pain was felt about the cecum followed by a condition of shock from which she soon rallied, but the pain spread rapidly over the abdomen. This subsided in eighteen hours. At the time I saw her she had a pulse of 90; temperature 100.5; free from pain except a sense of distension in abdomen; was bright and cheerful; insisted, in fact, upon getting out of bed and having her photograph taken standing, not over half an hour before the operation. These septicemic patients often manifest this cheerful disposition up to within a few moments of death. Operation revealed a diffused septic peritonitis, with a perforated appendix. The intestines were as lifeless as a rubber hose. The abdomen contained fully half a gallon of septic fluid. Irrigation and drainage failed to save the case because her diaphragm, spleen and liver were bathed in pus, and she was thoroughly saturated with the products of bacterial chemic changes.

An early diagnosis and speedy surgery would have saved this case, also. With the laymen operations on dying patients bring reproach to surgery because they fail to save the cases. This is true not only with the laymen but with some members of the profession. To me it seems that there are no plausible grounds for a diversity of opinion as to the proper course to pursue in the management of these cases when once a diagnosis is made. Let us, as practitioners and surgeons, get together on this subject. It is not necessary to provoke any ill feeling (which I have often seen done) in discussing this topic. Let our deliberations be friendly and gentlemanly, and sooner or later the truth will prevail and our patients will reap the beneficent harvest, the fruits of our mutual deliberations.

COLLES' FRACTURE.

Read before the Mississippi Valley Medical Association, November, 1894.

BY JNO. EPH. LINK, M.D.
TERRE HAUTE, IND.

I had kept no notes or reports of cases incident to the subject in hand until I determined to prepare a paper to be presented at this meeting; therefore I shall necessarily be somewhat limited in statistics, but hope in what I do by presenting a few typical cases to at least suggest an idea as food for thought. If I fail I hope you will pardon my presumption, and if I succeed that it may be registered as a merit of credit to the anatomic field of study, observation and labor.

Deformity in all cases is either the result of violence or muscular spasm from irritation, or both. In the case of Colles' fracture and other injuries of the wrist joint, this is indeed particularly so. Especially the progressive form from reflex irritation.

Some of the members present may remember my work on bandaging before the Society some years ago at Indianapolis, in which I attempted to show the advantage of a smoothly applied bandage in successive layers; this meets the indication in cases of injury to tissue, rest without restraint, and this in every instance must hold good in order to avoid irritation from the dressings, so far as possible, along with a too long enforced restraint and consequent loss of action of muscle. Yet, while we must necessarily use more or less force in the adjustment and retaining a fractured bone in position, I think I must have about perfected a happy medium between mechanical means and nature's resources.

In the first place, and as holding good in all cases of fractures, dislocations, etc., if the muscles are perfectly embraced in a gentle environment they "go to sleep," and thus half the work is done through the overcoming of spasm in reflex irritation. Then, by gentle traction and pressure well directed from time to time, progressively and frequently applied, perfect results may be obtained; whereas, on the other hand, if severe means are used and a single effort at replacement, great violence is done, and the results will be imperfect and more or less unsatisfactory. That any one method in the details of manipulation will prove equally successful in the hands of every one I can not claim, nor can we reasonably hope. As I often have occasion to illustrate, as showing the absurdity in the quibbles of council in medicine over different remedies in the same class: If two woodmen, the one with a crooked, the other a straight-handled ax, each having familiarized himself with the use of his tool, should enter into dispute, each claiming superiority for his kind; for any one must see that should they either one or both change, the results in the day's work at hand would be unfavorable. Each would do better work with the instrument he is most familiar with.

First in surgical success is knack, mechanical skill, more or less cultivated, with a thorough education in applied anatomy with its physiologic process, backed with practical experience and original clinical observation. The exception, as it may appear, to my general rule of bandage and position, "rest without restraint," without arbitrary environment and mechanical contrivances, is in this class of cases made necessary in the first place by the peculiar flatness (shape) of the forearm, wrist and hand;

and secondly the necessity of mechanical and somewhat forced means in bringing back to the normal line the peculiarly displaced and imperfectly separated fragment, more or less green stick or eggshell fracture, as it may happen to be in its nature according to the distance from the wrist articulation, sometimes involving the articular plate and strictly of the impacted or crushed eggshell variety. This latter, I think, I shall be able to show, can be remedied more successfully by my method of manipulation than by any other, not only in a larger per cent. of favorable results, but in every instance less deformity than has ever been reported. Why? First, by the taking off of muscular spasm before an attempt is made at adjustment; and secondly, by a gradual molding of the parts through well-directed means in the easy, snug-fitting environment, namely, nature's happy yielding to persuasion in the normal line. In all my work involving bandaging, especially next to the skin, I never allow myself to make a reverse. I allow the roller to run up a member, laying the bandage smoothly, and only use reverse when the limit of the part to be covered is reached. This can in many instances be done without the reverse turn, by passing around an enlarged joint, as the knee or around the hips; or, in case of the ankle-joint injuries, when the calf of the leg forms sufficient bulge with nar-

FIGURE 1.

rowing above to enable me to get the descending spiral. In thus laying on in the obliquely longitudinal we get strength and support in keeping the bandage from slipping, and avoid the rolls or thickness and like results by which the skin is creased and the physiologic function of the tissue is more or less interfered with.

I here present you with two splints from a case treated as shown in photograph No. 1, the palmar or anterior, and dorsal splint, hurriedly shaped out of a cigar-box lid with a dull pocket knife. The shaping at the distal, or palmar end is done, as you may see, much in the fashion of the old Day's splint, and is left just long enough to catch a turn of the bandage as it embraces the metacarpal region below the thumb; and in the shaping of this extension we simply accommodate it to an easy fitting in the fold between the enlargement on the thumb and little finger borders of the palm. It will be seen to consist of a short acute curve, so as to fit the muscular enlargement at base of the metacarpal bone of the thumb; the other longer and less curved, nor so deep, to fit that at the base of the fifth or little finger metacarpal and carpal enlargement. The dorsal splint you will see is, in this instance, made of a cigar-box lid. The lower end is made to correspond in width

to the bony structure of the hand at a point just below the thumb, about midway between this and the knuckles, or metacarpo-phalangeal articulation. You will observe that the splint I here show you is curved in its general outline in its upper two-thirds, and has been shaped in the manner to be suggested, and merely shows the outline of the forearm, and while a certain kind of board has been used in this instance nothing more is required to carry out the principal of dressing intended to be taught than to lay a thin piece of board (zinc or tin will answer as well as wood) of sufficient width and length and mark it on the reverse side, using the well limb for a pattern. Cut it a few lines narrower than the member with an idea of the limit of the bony structure. I should recommend that for comfort and the very best results; the upper end of the short or palm splint should be almost or quite the width of the limb at the corresponding point. Here, now, we have a crude frame-work of our dressing, but like that of a finely upholstered piece of furniture it will soon be out of

FIGURE 2.

sight, and to all outward appearances out of reckoning. Yet it is no less an essential part, like the solid foundation of a grand superstructure in building. The dressings in compress and bandage, as you shall see, will finally meet all indications to reshape the disorganized and displaced fragment of fractured bone.

First, now I should cover the surface of the splint with two or more thicknesses of old soft muslin, as a general precaution against violence in pressure or rubbing of the sharpened edges against the skin. For compresses they must be of full sufficient thickness to fill in the natural depressions carried to a little more than a straight line with the prominent points of bone included beneath the splints.

I find on inspection of the dressings removed from a lad of twelve years, a photograph of whose arm I show you (see photos. Nos. 2 and 3 results), that the long compress extending from the upper broad end of the short or palm splint to a point near to the thumb curve, is six thicknesses. This, with the edge

of the splint slightly beveled and considerably so in the concave at the upper end, fulfills the main idea in fitting and skin protection against mechanical irritation from the splints. Now comes the more important point, that of proper shaping in adjustment of the bone with a view of the normal, or non-deformity.

I have here, as applied in this case, a compress of rather thick old sheeting, ten layers, about $2\frac{1}{2}$ inches in width and an inch possibly wider than the splint, thus filling in the space at the edge of the splint so as to form an easy embrace of the limb beneath the splint and secondary bandage. This is placed upon the splint so as to extend from a point above the enlargement of the lower end of the radius to within an inch, more or less, of the upper end of the splint, as indicated by the length of the splint in accordance with the depression in the curvature of the normal or sound bone. On this I have laid another of eight thicknesses about two-thirds the length of the other and half its width. (See photo. No. 4 of compresses in place on splint.)

In this case we have what fits almost exactly the

FIGURE 3.

well limb, possibly a little more than a filling of the curve to a straight line. This will always be a wise provision as there will be a hundred chances to one of too little rather than too much. The tendency always being to displacement backward, as we almost invariably find it in such cases of injury.

As second in importance we will look to the padding beneath the dorsal or long broad splint. Here I find a covering of muslin wrapped about more or less securely, adjusted with a view of preventing its slipping and displacement beneath the bandage after adjustment. All this may be omitted, as the abrupt corner at the ends over which the bandage should be made to lap will be sufficient to keep the splint well in place. But here again comes in the element of precaution of being on the safe side against possible defect where defect alone can possibly obtain. We find on the lower end of the splint a broad compress of several thicknesses of muslin, broad enough to overlap the edges of the splint and of only sufficient length to extend from the point of fracture over the articular end of the radius, down over the carpal

bones and all, to a point near the end of the splint. Another compress of about the same thickness, commencing about 2 inches above the upper end of the lower one and well above the fracture point extending to a point above within an inch or less of the upper extremity of the splint. The idea here involved is to allow some latitude for motion between the abrupt ending of the splint, together with as you see, in photograph No. 1, the cutting out of the edge to a bevel and concavity, so as not to do violence to the skin. While the front line along the lower end of the radius is nearly straight, the danger of its remaining too low seems to me to require this additional precaution in so padding the two ends of the splint, the one over the distal, the other the proximal ends of the fractured bone with an open space between. Now with this padding and the cutting out of the ends of the board to a concave we have our mechanical contrivances complete, and with the patient before us we begin with the wet roller bandages, always of soft, well-worn muslin. With physiologic processes in view I now begin at the point of injury embracing the wrist joint; laying the bandage with firm and gentle binding, allowing it to lie smoothly, the roller running more and more spirally as the bulging of the limb directs, until the elbow is reached, when, after a

FIGURE 4.

turn above and over the olecranon process with forearm flexed to or near a right angle with the arm, the bandage is easily made with a circle or two in the descending spiral to reach the wrist and around again. Probably this time or the next I shall allow the bandage to encircle the hand below the thumb, then up over the wrist and, as before, embracing the muscular part of the limb with some view to the controlling of muscular action, spasmodic and voluntary—all desirable in the view of necessary rest to the fractured ends of the bone. I so continue, roller after roller and layer after layer, until I feel that the indications as above are fulfilled, avoiding unnecessary and cumbersome dressings. Now I place my short or palm splint and compress with a few turns of the wet roller, until it is snugly but not tightly held in place. After satisfying myself that the splint is in proper place, its surfaces on a plane with the bones of the wrist, the palm of the hand resting flatly against the body while the patient stands with elbow flexed, I now run an additional roller a few turns around so as to embrace the upper and lower ends of the splint, taking a turn or two about the metacarpal region below the thumb so as to catch the palmar projecting front as well as the upper end of the splint and firmly fix it in the longitudinal to prevent it from slipping up or down. We

now have it all well fitted to its mechanical shapings, not only in the depression and prominence, but as you see extension by gently inducing nature to seek the point of comfort as per the fittings at the base of the hand.

We next take up the dorsal splint and compresses, placing them as above arranged, and with many turns of the wet roller up and down from the knuckles, the edge of the bandage overlapping the end of the splint around and up to the elbow, or at least well above the upper end of the splint, until the fixation in adjustment of the splint is perfect. I now grasp the embraced member, firmly pressing the two splints together with one hand while with the other holding the hand as in friendly embrace in hand-shaking. With gently increased pressure on the splint and simultaneous pulling in extension I make the first forced effort at adjustment. This is only done to the point of endurance of the patient short of suffering;

FIGURE 5.

in fact few complain at all, as the action is so perfectly in line with the normal and entirely free from muscular spasm, owing to the easy and even compression by the environments, that a sense rather of relief is experienced. Many have told me that from beginning to ending of the dressing and extension, the sense of relief was marked. After a somewhat extended pulling and pressure by gradually applied force up to my full power, so maintained to the tiring of my arm to a stage of necessary rest, I as gradually relax as I applied the force. The limb is now placed in an easy sling suspended about the neck in easy flexion at nearly right angle, looking well to it that no binding from a cord-like rolling and tightening of the bandage about the elbow obtains. I dismiss my patient for twenty-four hours with the injunction to keep up somewhat constant passive motion and massage of the hand of the crippled limb by that of the well; the frequent and somewhat extended elevation of the hand from

time to time with a view to avoiding congestion and stasis with painful results in swelling with tightening of the bandages.

The next day, and the next, I see my patient, looking to it that my general instructions are carried out; that is, that the fingers are supple, the hand spread by pressing in the palm; that there is no undue swelling from lack of the precautions given, especially that of extension with extreme elevation of the hand. I again grasp with very gentle hold, and careful precaution against causing pain, in the effort at further and gradual extension and proper continuous and progressive adjustment of the fracture. This can safely be deferred in some measure until the stage of congestion and extreme irritation has passed, which will be by the fifth or sixth day, when you can use all the force in your power both in grasping and pressing the splints firmly against the bone without causing suffering on the part of the patient, but with comforting assurance to yourself, and which you can impart to him, that the bone will necessarily be in perfect adjustment and as good as ever if continuously and persistently persevered in for a sufficiently long period of time. And now comes the time to see and instruct the nurse, some member of the family or other person who can be relied upon as in constant attendance, to grasp the limb and make extension as you have done, and you must carefully

FIGURE 6.

instruct them. This may be done, and if at all possible should be done every three or four hours, and at least three or four times a day. The patient can, if properly instructed, with some comfort to the tired feeling of the confined muscles do much in this line by massage of the forearm, hand, fingers, etc., making, at frequent efforts, some extension by grasping the fingers and hand and pulling on them, bringing only the muscles of the arm above the elbow into action (never below) of the injured limb. Six weeks should be the limit of such treatment and even longer is safer, and I have no doubt in many cases better and in all safer as against deformity from enlargement in callous, exostosis, etc., the results of a lingering tendency to chronic irritation and inflammatory new formation deposits.

The case that I am able to present to you to-day in a photograph of the injured member and from which these dressings here were removed is a typical one in point of not only ordinary results of such treatment but extraordinary, in this, that he had, prior to this injury and but a few months before, suffered a similar fracture of the same wrist, and from neglect to follow out my instructions (not coming to see me and I unable to find his place of residence, he removed all dressings in four weeks) with the result of excess of callous enlargement and some consequent deformity. I had by mere chance met him, and on recognition called

him to my presence for examination, and made some uncomplimentary criticism of his neglect to self and slighting of my injunctions in behalf of his future welfare, the good of science and my reputation as a bone surgeon, so much so that he came at once to me and followed out my instructions, this time, to the letter. Not only this, but on my leaving for Europe he promised to wear the dressings the prescribed time of two months. He did better; presenting himself to me on my return still wearing them, ten weeks from date of injury, February 27 until May 6, 1894. There is now, as you see, no enlargement of the parts immediate, mediate or proximal. I am sure that an expert would find much difficulty in data of evidence to identify the member injured or distinguish between the two, injured or non-injured.

Arthur D. K., aged 20, was injured by falling on the left hand, from a leap in the air in an effort to take high ball, when he was struck by a fellow player and knocked from the erect equilibrium: he fell full force on the hand, the whole weight of body striking the arm: thus weight and leverage were brought to bear in producing a typical Colles' fracture—the radius being fractured about 2 inches more or less above the wrist joint, the bone being bent in its opposite curvature from the natural, with a resistance in an effort at replacement which shows green-stick fracture conditions. I use a primary or skin

FIGURE 7.

bandage with wetted roller of old well worn muslin covering with two or three thicknesses of spiral layers, one turn encircling the limb above the elbow joint, descending to the wrist and up again, and so on. The cigar-box splint used on the anterior or palmar surface I here present also in likeness from photo. No. 2; likewise the longer and broader dorsal or posterior splint. The anterior compress is composed of a piece four thicknesses $4\frac{1}{2}$ inches long; another laid in the center of this $2\frac{1}{2}$ inches long of six thicknesses; a third 2 inches long consisting of twelve thicknesses, and on to this $1\frac{1}{4}$ inch long of six thicknesses. This is formed from my judgment and by testing on the well arm as to the thicknesses required to fill in the natural depression, or to bring the injured and displaced bones to the natural line in curvature. The dorsal splint is padded with two compresses. The lower one is $2\frac{1}{2}$ inches long of eight thicknesses. The upper 3 inches long consisting of eight thicknesses and are placed two inches apart, leaving a vacant or hollow space over the center of the line of depression. These are placed, as intended, on the splints and secured to the injured hand with roller bandages well wetted: first the front with two or three layers of the bandage, with a turn or two below the thumb catching the palmar point, the upper limit embracing the broad upper end of the splint, one edge of the bandage embracing the splint the other the forearm just above, and this throws my bandage back to the descending spiral to a point above the wrist or hand as preferred. Then the posterior splint is placed with its compress and secured much in the same way. The two splints are now in position, at almost exact parallel as to their transverse axis. I now grasp the encased limb, at a point about opposite the injury, with my right hand, fingers to the dorsal and thumb to the palmar, and grasp the hand as in a warm friendly

shake, making with my left gradual extension and pressure at the same time. The patient declares he suffers little or no additional pain, and in fact less than the continuous suffering from time of injury until the commencement of dressing with the primary bandages. He declares that from the moment of commencing the bandaging relief was general and continuous; before, the bones seemed to be getting more and more out of place, pricking painful and causing the muscles to harden in cramps. After the pulling there was no additional pain or soreness, rather less than more: rested a good part of the first night: restless more from restraint than pain. At 1 p.m., the next day I find no pain caused by the extension: says that every time it is pulled upon by assistant a decided sense of relief is experienced. There is little or no swelling, patient using passive motion, kneading and pulling the fingers gently with the well hand. June 1: no swelling of the fingers and no pain, and little tenderness to touch, grasp or pull of forcible extension. June 2: the least perceptible swelling, a slight puffiness of fingers and thumb: dressing a little loosened from shrinkage of the limb. Apply a roller of dry bandage for cleanliness and some addition physiologic support. "I am surprised at the small amount of pain I have suffered," is the voluntary and impulsive expression of the patient following a full power of force-pulling and grasp of the splints, prolonged for four or five minutes. Patient instructed to call at noon tomorrow. June 3: there is no soreness, no tenderness, and gradual and continuous pressure in grasping the splints to my full power, with the like pulling causes only a sense of comfort, relief and strength to the tissues and muscles involved. The patient smiles pleasantly as he assures me, and his brother present, that if all severe surgical operations and dressings were no worse than this they will surely not amount to much. I see the patient the 4th, 5th and 6th. June 8: remove outer bandage and both splints for the purpose of assuring myself that the adjustment was perfect, palm splint compresses sufficient for normal curve, etc. The skin or primary bandage is not removed: added an additional compress of four thicknesses $1\frac{1}{2}$ inches long and another of twelve thicknesses $1\frac{1}{8}$ inch long on anterior or palm splint. No change in dorsal. All compresses are carefully preserved in their exact place on the splint and replaced precisely as they were originally on the arm, the splint mark on bandage and hand enabling me to do this with precision. June 9: saw the case with view of examining as to circulation of hand. All in good condition; patient perfectly comfortable, even on pressure and pulling. June 10: saw case: all well. June 16: removed all dressings, bandaging and splints to the skin and bathed the limb. I replaced all dressings with fresh bandages, using same compresses carefully kept in place on splints and replaced with exactness as before. Saw the case for two consecutive days. June 22: redressed as on the 15th. Arm appeared well; patient using hand as if nothing the matter. Dressings from now on are used only as compresses to insure against excessive callous. Removed anterior splint July 9. Bandaged the wrist July 16. Rebandaged wrist with flannel. There is absolutely no means of distinguishing a difference in the two wrists. Patient working at manual labor, firing an engine. (See photograph after treatment.)

Case 3. Walter Fry, aged 11, injured June 19 by falling from a grocery wagon to the street, striking open palm on the ground doubling the limb back with weight of body on it: body lying prone upon the ground. Dressed in the usual way with wet roller bandage of old soft, well-worn muslin. Primary bandage of two or three layers covering skin with view of controlling muscular spasm. Length of arm from tip of olecranon process to tip of the styloid process, 8 inches: length of palmar splint in full to the tip between the palm folds, 7 inches: circumference of wrist, $5\frac{1}{4}$ inches: width of palmar splint at wrist, 2 inches: circumference of arm at point of upper end of palmar splint, 7 inches: width of upper end of palmar splint, $2\frac{3}{8}$ inches. First compress four thicknesses, 5 inches long, commencing one inch from upper end extending down to palmar folds. The second compress four thicknesses 4 inches long, commencing $1\frac{1}{2}$ inches below the upper end. The third one eight thicknesses (four 2 and four 3 inches long), commencing $2\frac{1}{2}$ and 3 inches respectively below the upper end. Length of dorsal splint, 8 inches: upper end, $2\frac{1}{2}$ inches wide: lower end opposite the thumb juncture to hand, 3 inches: opposite the fracture, $2\frac{1}{2}$ inches. One thickness of muslin covers the whole surface: upper compress six thicknesses, $2\frac{1}{2}$ and 3 inches (three each respectively) in length, commencing one inch from upper end and extending down to a point a little above the fracture line. Lower compress six thicknesses 3 to $3\frac{1}{2}$ inches long, commencing at half inch from lower end of splint to a point just below the fracture. The palmar splint was first secured by a number of turns up and down the splint around

hand below thumb, catching the narrow point of palmar splint below and embracing the upper end with a turn, allowing a half-breadth of the bandage to lap over on the forearm above the splint, then giving acute reverse to the spiral ascending, thus making it descending, then up and down, lightly but well fitting. Next the dorsal splint is applied, much in the same manner, a number of layers thus giving a soft, thick and firm encasement. I now make gentle (in beginning) pressure and pulling, one hand grasping splints, the other to the hand, increasing to full power of pulling and pressure. I finish by enjoining constant manipulation by the patient with well hand to press, knead, bending and straightening the fingers and thumb, a most important matter in comfort as well as in final results of suppleness, non-ankylosis and general deformity as usually charged to rheumatism, truly a nervous or neurotic condition, similar to above attributed cause, but a reflex from irritation, non-use, etc. I see the case every day, and on the 25th I remove dressings and examine the condition of the parts. I find bone well in position, but not quite enough curve. I add a compress of eight thicknesses to palmar splint, length, $1\frac{3}{4}$ inches, and redress as before. See my patient every two or three days at home or at my office. June 29: redress, adding compress of eight thicknesses to palmar splint, length $\frac{3}{4}$ inch. July 6: redress as before. Action of joint, hand, fingers, etc., perfectly normal. Measurement of wrist at styloid process, $5\frac{1}{2}$ inches: at point of fracture 5 inches, exactly in harmony with the uninjured. I see the case July 17: remove the splint and bandage wrist with a few turns of muslin bandage. Should prefer, if at hand, light new flannel, four or five turns around the wrist-joint pretty tight, as the parts are now used to it, and is best a little tight as a precaution against neoplastic action and for firm support. The case is dismissed with injunction to call from time to time for fresh clean bandages to be worn for two months. July 20: rebandage the wrist. July 30: rebandage the wrist. The bandage had slipped up from the external styloid process, and there are consequently evidences of some thickening of callous. Patient dismissed as safe against possible trouble after the limit necessary to wearing present dressing. (See photo. No. 6).

As these cases were all of the true Colles' fracture variety, with fracture of the shaft about 2 inches above the joint, I can only assure you that equally good results have invariably obtained under similar dressings and treatment where the injury was strictly confined to the articulation, with or without impaction or crushing of the articular cartilage. This latter condition is sometimes difficult to differentiate from sprain or injury to scaphoid or semilunar bones, all of which are liable to produce ugly deformities, more so than where the fracture is higher, with progressive crippled function and pain.

A typical case of this condition came under my observation a short time since. The sufferer was a woman past fifty years of age, in the middle walks of life, a housewife. The case when first injured fell into the hands of a general practitioner and able young surgeon, and should only go to show the difficulties attending the diagnosis and successful treatment of this class of cases. I had a photograph taken showing the two hands in comparison, the injured and uninjured. (See photo. No. 2, Case No. 4. The function of the wrist is much impaired and there is constant increasing deformity and pain. Whilst these conditions are of more or less common occurrence, coming frequently under the observation of the surgeon, and unavoidable in at least a small per cent. of cases, yet I have under the above treatment had universal success for over twenty years in surgical practice. And whilst I consider fracture of the long bones and injuries to joints the most difficult work of the surgeon, never to be attempted if possible to be avoided, by the busy general practitioner, yet, with the above course of handling, there will be no occasion for deformity or crippling either in Colles' fracture or the latter; and whilst the anterior compresses are not needed in replacing fragments of bone

as in the true Colles' fracture, yet they are of equal necessity with the bandage and splints in fulfilling the indication for comfort—"physiologic rest."

In not a single instance under the above treatment have I had a case of deformity recognizable by the laity nor of discomfort to the patient. The only point making it possible of recognition by the expert is the less prominent external styloid process and head of the ulna, but in no sense involving a displacement, as usual, of the styloid process. This obtains through the pressure of the posterior splint, and is avoidable, if particularly desired, by using a thicker posterior splint—compresses cut out to fit the uninjured member.

THE MERCURIALS.

BY S. V. CLEVENGER, M.D.
CHICAGO.

Many of the older remedies need a vigorous scientific reconsideration from the newer vantage grounds afforded by modern laboratory methods. Certain physical and chemical properties of mercury and its salts, if properly studied in connection with the vast mass of undigested clinical knowledge accumulated during centuries, enable the mercurial group to be singled out as having peculiarities that separate it completely from all other remedies, including those with other metallic bases.

Chemistry and physics are woefully neglected sciences in even the best medical schools, and to this fact is attributable the empiricism of our therapeutic work, and whosoever is equipped with physical and chemical knowledge before becoming a physician will find himself unintelligible to the vast mass of his confrères in an endeavor to utilize those fundamental branches in connection with physiology, pathology and therapeutics. The chemistry of *materia medica* is left to the manufacturing pharmacist, though it is closely interwoven with biochemical suggestions temptingly held out to any chemical physiologist with the means, disposition and ability to correlate these fields, and thereby win imperishable honors.

Quicksilver is fluid at common temperatures, which conjoined with its great weight and disposition to vaporize, whether cold or hot, sufficiently set it apart from metals generally. Its cohesive power is great when pure, and lessened by impurity admixture. Poured upon a level surface motion may separate off large and small globules difficult to handle; but whether an ounce is divided into ten or a million distinct drops all of them can be readily run into a single mass again by mere approximation of the particles. It is visibly affected by temperature changes, and a very old trick consists in concealing a quill, containing a little mercury, in a hot hard boiled egg, the capering, rolling and jumping of which amuse and mystify children. Glass barometer tubes in the space above the top or "meniscus" of the mercury column accumulate the vapor of the metal, even when hung in rooms with fairly even temperatures. The great specific gravity of mercury makes it useful to gold miners through its insinuating among the gravel, sand, earth and water, lubricating its way and mixing with the gold, "floating" the less weightier materials above the amalgam. Some miners have been known to swallow several ounces of mercury to move their bowels, and they claim to have secured a rapid and satisfactory result while the mercury appeared to be little sepa-

rated in transit. Invagination of the intestines is occasionally treated with heavy doses of the metal, though not so often as in the earlier part of this century. A few years ago I saw the inflamed and softened small intestines, in a case of the kind, perforated and ruptured by a heavy dose of mercury, causing death before the laparotomy which might otherwise have saved the patient. To a considerable extent what mercury accomplishes in masses in larger tubular structures it may likewise do in smaller cavities when broken up into lesser particles. In absurdly large quantities the metal sinks swiftly through the enteric tract, pushing, crowding, mixing with what it encounters, gliding by, or under, loose material, distending soft receptacles, if obstructed, percolating and comminuting fecal masses, increasing peristalsis, altering their tendency to cohere, and lifting them away from mucous surfaces, finally gravitating in advance of the materials it has mechanically lubricated toward an exit.

Dust and grease dim the surface of mercury and agglomerate to some extent with the mass; from such impurities the quicksilver can be freed by running it through filter-paper cones with pin hole apertures, or by sublimation. Often the filter paper continues to be soiled after repeated attempts to separate the dust, showing that minute particles of foreign matter had been concealed by the metal, though it was apparently clean, a physical peculiarity to be remembered when we reach a consideration of its phagocyte-like physiologic effects.

Bache¹ sums up the general ignorance of the therapeutic action of mercury in these words: "Of the *modus operandi* of mercury we know nothing, except that it acts through the medium of the circulation, and that it possesses a peculiar alternative power over the vital functions, which enables it in many cases to subvert diseased actions." In an inaugural thesis before the Chicago Biological Society, Feb. 4, 1880, and in subsequent papers,² I announced the progress of original continued physiologic, microscopic and chemic observation upon the therapeutics of mercury and its compounds, and shall now review my former articles with such revisions as the succeeding years enabled me to make.

The prevalent medical opinion on the subject is that some unknown compound is formed by the metal and by its salts in the system. Mailhe claimed that the bichlorid was formed in the stomach, but failed to establish his theory. Maisch, Bucheim, Oettingen, Winkler and Jeannel dissent from Mailhe's view. Jeannel suggests the probable formation of the black oxid in the alimentary canal. Maisch denies that this takes place, or that black oxid occurs in old pill masses. Sée argued in favor of an albuminate of mercury as the active agent elaborated in the body. Odling thinks mercury acts as a red blood globule carrying oxygen to tissues. Had any one of these views been established, the mystery would have been no nearer solution. Investigators seem to have been lured away from evident and fundamental principles in imagining no connection between the easily discernible physical properties of mercury and its therapeutic effects, assigning the drug occult, catalytic properties.

Physiologists do not disregard the mechanical properties of water, yet mercury has never been considered from this standpoint. Both water and mercury are fluid at common temperatures; both vaporize at all temperatures; both change their specific gravities in passing from solid to fluid and thence to vapor; both maintain extreme division of their particles under certain circumstances, and by loss of heat or under compression cohere in drops and fall. The great difference is that mercury is fourteen times heavier than water and has a different solidifying point. I claim that the simple mercurials, such as *pilule hydrargyri*, *unguentum hydrargyri*, *hydrargyrum cum creta*, *emplastrum ammoniaci cum hydrargyro*, *emplastrum hydrargyri*, *unguentum hydrargyri compositum*, *linimentum hydrargyri*, *suppositoria hydrargyri* and the oleate of mercury depend for their medicinal properties upon the metal being finely divided, and in proportion to the extent to which this division is carried the therapeutic effects of the drug are augmented. A grain of mercury undivided may have no physiologic value, but when it is separated into a hundred thousand globules and held by an excipient, as in blue mass, from forming large particles, the well-known effects of blue mass are obtained, and the more potent the pill the greater has been the division of the metal. The confections, fats, oils, and other substances, with which mercury in this is blended by the pharmacist, impart nothing to it that changes its character. Though occasional oxidation may occur it will be seen that this is of no consequence whatever. My experiments proved that mercury underwent no change in the system after ingestion, and that it was fully capable of producing all its therapeutic and poisonous effects by circulating in, or obstructing, the microscopic channels of the body.

The first eight mercurials mentioned above contain globules of the metal ranging from one five-hundredth to one one-hundred-thousandth of an inch in size, mixed with substances more or less inert. The first numbers one hundred thousand globules and upward to each grain of mercury in the mass; the second is much more finely divided; the third is badly divided, some of the globules being quite large, as the chalk does not prevent confluence, and it is therefore an unreliable form for administration. The "oleate" contains very minute globules reduced by the oleic acid from the yellow oxid with which it is incorporated. The metal constantly precipitates from this form until very few globules are suspended in the oil. The other mercurials vary more widely in the quantities of mercury they contain, but none of them convey mercury into the system in any other than the metallic condition.

No other metal is capable of comparison with mercury in its mechanical properties and physiologic effects. It is the only metal fluid at common temperature; it resists separation into smaller masses and tends to form larger globules when divided, unless held apart by some substance that will coat each particle separately. Each minute sphere will adapt itself to the shape of the tubular or intercellular space through which it may pass, and will by virtue of its superior gravitating power cleanse many of the parts through which it circulates. The myriad globules released in the stomach and intestines permeate the glandular structures, blood vessels and lymphatics, and act as "alteratives," as we could imagine a foreign body having its weight and adaptabilities, would act when introduced into circulating channels. The dis-

stances between the globules prevent the larger sized masses from forming, and even when lying compactly an albuminous coating will effectually prevent cohesion until such covering is broken. I kept for a month a mass of globules shaken up in albumin, and found, after having given a dose to a frog, that the globules maintained their sizes in the tissues of the animal, and that but few had run together by rupture of the enveloping albumin in the stomach, this being easily recognized by the larger sized globules and the silvery luster of the metal which the coating had previously dimmed.

No one disputes the fact that blue mass contains minutely divided mercury, but nowhere have I found any opinion as to the probability that the *mercury alone* thus given produced its well-known effects. Histologic tissues and a finely divided metal have not been considered as amenable to mechanical principles. Both being microscopic are at once relegated to mysterious modes of working, though a billionth of an inch is as much an entity as a billion miles. When the metal, in an undivided or uncombined state, is administered, it rapidly passes through the intestines, without any apparent effect. The cohesive properties of its component particles resist separation. The metal must be well triturated with an excipient to reduce it to globules; shaken up in water a temporary, uneven, yet pretty fine division may be made, but the water opposes only very temporary resistance to the metallic confluence. Honey, fats, oils, confections, etc., when mixed with the fine globules, tend to keep the particles apart. Albumin and glycerin effect a separation better than many substances.

Finely divided mercury presents a grayish appearance, passing into black as the division is made extreme, this condition favoring the reverberations of light from particle to particle until no rays are reflected to the eye. The microscope shows that no change from the metallic state has occurred in reducing the metal to this form. To count the globules in a gram (15.4 gr.) of blue mass I spread it mixed with water over a square decimeter of surface and found an average of 2,000 visible under a very low magnifying power in an area of a square centimeter, which would make 200,000 of these globules in a gram. But under an objective magnifying seventy diameters, more than ten times as many became apparent. Dr. Lester Curtis estimated the size of these globules at from one six-thousandth of an inch to sizes almost immeasurably smaller. In a gram of pill mass there is one-third of a gram of mercury, which would cubically measure one-fortieth of a cubic centimeter. Taking .01 millimeter (Kölliker) as the average diameter of the capillaries, the division of this mass into twenty-five million globules would suffice to reduce all the mercury to capillary sizes. But all are not so reduced, though many are divided up very much smaller. Carpenter³ asserts that metallic mercury, finely divided, can be absorbed by the blood vessels from the alimentary canal. If these minute globules drop unchanged into the glandular tubules and force their way to the blind extremities, the expulsion of less heavy contents from these tubules would occur necessarily without reference to whether such contents were morbid or normal. In this manner a deobstruent action is obtained by as simple and effectual means as by cannon balls dropped into a large pipe. Peristalsis would assist in passing the same globules onward to other

³ *Physiology*, p. 138.

secreting and excreting surfaces, and a few globules of the proper size would thus change the conditions of a large area of minute tubules. After passing the pylorus the simple follicles and duodenal glands are affected as were the gastric tubules and, by thus cleansing glandular structure, restore normal secretion, or, in some cases, induce hypersecretion. The intestinal villi and lacteals pass the metal into the circulation, while the portal vein carries most of it direct to the hepatic parenchyma. Somewhat as the direct aortic connections with the carotid render embolismus most frequent in the left cerebral artery, the peculiar relationship of the inferior dental arteries with the external carotids facilitates mercury accumulation in the cancellated tissue of the inferior maxillary bone, with resulting tenderness and sponginess of gums. The minute globules find easier ingress to, than egress from, the dependent portion of the lower jaw bone, where they accumulate to exert a slow but sure disturbing effect upon the gums and incisors, and finally the molars. The irritation of the globules upon the peripheral nerves of the salivary glands, together with the detersive influence of the metal itself, already mentioned, accounts for the activity of the sub-linguals, sub-maxillary and parotid glands in ptyalism. The question arises, why catharsis does not continue during ptyalism if all glandular structures are affected: the liver being caused to secrete more bile as the maxillary glands are stimulated to salivary excretion? In the first place, the innervation of all glandular structures is not alike, hence they are not comparable in their actions: next, ptyalism succeeding catharsis shows that while the liver and intestines evince the first effects of mercurial ingestion, the superior glands are reached later through the circulation. From this it may be reasoned that mercury inunctions impress the general system rather than the liver or alimentary canal, and this has been proven clinically.

Mercurials load the circulation and emunctories with effete matter because of their deobstruent effects and ability to insinuate their particles among all tissues, separating some morbid or ulcerated portions from the healthy, by the great and universal law of heavy bodies acting in the line of "least resistance." If the bile is improperly diverted or suppressed, it restores it, by opening the channels through which it normally flows; if superabundant from organic obstruction it would regulate its quantity in the same way by affording exit for morbid causes. Its aplastic action is due to the capillary and lymphatic cleansing it produces: the million minute globules pushing open circulatory channels and preventing accumulation, as well as affording means for absorption. Provisional callus and wound healing is interfered with by globules breaking up new tissue and interfering with its formation as would any foreign substance. Mercury has been distilled over in considerable quantities from the bones of those who have died from mercurial cachexia, the little particles finding stopping places in the cancellated tissue removed from more active circulatory influences, and, in excess, doubtless dissecting away the periosteum, filling the lacunæ and canaliculi, thus producing caries.

Eld, Buchner, Cantu, Jourda, Anduoard, Fourcroy, Gmelin, Byanon, Mayençon, Bergeret, Sakowsky, Osterlin and Heller have found mercury, regardless of the form given, in the blood, urine, serum and pus of ulcers, in the saliva, feces, seminal fluid and aborted

fetuses of salivated women, in every conceivable secretion and every tissue. Naunyn⁴ says: "It has been proved by good observers that mercury is of relatively frequent occurrence in the bones in quantities readily discernible to the naked eye. Years after mercurial treatment, I have found it in biliary calculi. . . . If an albuminate be formed it must be again decomposed, for elimination of mercury sometimes occurs in non-albuminous urine, while albuminous urine sometimes contains free mercury. Mercury is also eliminated by the bile, saliva and sweat. In the finest globules, it is to be found in the bile, urine and feces after inunction."

Taylor⁵ recovered globules from the brain and liver which averaged $\frac{1}{260.6}$ of an inch, while those recovered from the kidneys were still larger. Very often the word mercury is used in a loose way by authors to include the salts as well. In these cases the usual chemical tests were evidently applied for the base, and the radical was undetermined. The microscope would have been effective enough for the discovery of the metal, but nowhere does any use appear to have been made of this instrument in these investigations. Bowman says: "When the presence of mercury is suspected in the viscera or other tissues of the body, the part intended for examination should be first cut into thin slices and then heated with hydrochloric acid and chlorate of potash, by which means any mercury that may be present will be converted into the bichlorid, and thus brought into a state of solution." This method will detect mercury, but not the elements with which it has been combined. The microscope should first be used. Brande and Taylor⁶ say: "Globules of the $\frac{1}{800.0}$ part of an inch in diameter may be easily recognized by the aid of a microscope. Their perfect sphericity, their silvery whiteness by reflected and complete opacity by transmitted light at once identify them as metallic mercury."

The occasional tonic influence of the metal would follow wherever glandular obstruction was superinducing diminution of the red blood corpuscles. Mercury is not a tonic; but as it increases secretion, removes obstructions and sets the corpuscular manufactories in order, as it does the biliary, it induces tonicity. But mercury also causes anemia, and this might be expected from persistence in its use, when occlusive powers, in closing the minute passages and tubular structures which, in medicinal quantities, removed preëxisting obstructions, are remembered.

Mercury in large doses diminishes red blood corpuscles, produces anemia, emaciation, ulceration, febrile symptoms, with a peculiar "jerking, thready" pulse. Obviously a salutary effect upon the glandular system, wrought by small doses, becomes pernicious by overdoses, and hematosis is seriously disturbed by vascular stasis induced by mercurial plugging of the arterioles and venules. Any irritation causing hepatic and splenic function perversion is certainly followed by hemic degeneration, and the pulse characterizing hydrargyria is, in my opinion, due to the irregular but frequent propulsion of blood by *vis a tergo* clearing of the lesser vessels where the metallic globules had for awhile backed up the current till forcibly overcome. This leads to the consideration of the nervous phenomena among its toxic effects. Mercury produces ulceration, neuralgia,

⁴ Ziemssen's Cyclopedia, p. 615.

⁵ On Poisons, p. 389.

⁶ Chemistry, p. 491.

paralysis agitata, epilepsy, often melancholia, all of which can be produced by thrombus, embolus, passive or active cerebral or spinal congestion, or resultant anemia directly wrought in the way mentioned.

Take any treatise on nervous diseases, and wherever the words clot, thrombus and embolus occur, substitute mercurial accumulation, and the cause, in my opinion, is fully explained. Accumulation in the terminal twigs of the cerebral cortical arteries would induce paralysis, paresis, softenings, tremors, hemiopia, amblyopia, etc., according to location, and whether the basilar or carotid supply contained the larger quantity of mercury. Should the middle cerebral artery be the meeting place of the molecules, according to subsequent arrival of the metal thence, aphasia, hemiplegia or anesthesia supervene, singly or together, depending upon whether the gyrus operculum, insula, optic thalamus, corpus striatum, crus or internal capsule had become congested or deprived of blood by this interference.

Bumstead⁷ relates a case of epilepsy as due to syphilis neurosis, which can be better accounted for as mercurialization. The patient had been subjected to a long course of mercury, and manifested neuropsychoses quite compatible with the supposition that the mercury was their cause. Bumstead gave more mercury with iodid of potassium and was gratified with immediate benefit. The iodid alone would have been the better remedy, as iodine unites directly with mercury to form mercurous iodid. That mercuric iodid is not formed, is evident, from absence of the physiologic effects of this active compound. The less soluble mercurous iodid is carried back into the circulation from the bony or vascular recesses in which the iodine united with the mercury, and decomposing, leaves the mercury to reproduce the same phenomena as when first ingested, with the advantage that the excretory channels have a better chance to eliminate the mercury while circulating than when lying dormant in inaccessible places. This explains why the iodids re-salivate the mercurialized.

Finding the metallic mercury "in every conceivable tissue and fluid of the body" warrants the supposition that diabetes, vomiting, gastric and pulmonary irritation following hydrargyric exhibition are owing to nerve-center irritation, mechanical and direct, in the floor of the fourth ventricle, or to interference with its blood supply. At this stage an augmentation of the salivary flow by irritation of the chorda tympani nerve might also be expected, and this may be among the initiatory sialagogic causes. This irritation is exerted upon the nerve-centers by the heavy globules of the metal, exactly as serous or purulent accumulations are mechanically productive of nervous and mental derangements, or that mercurial interference with the circulation thereabouts would be followed by such neuroses.

The elimination of mercury from the system seems to be principally through the kidneys; but gold rings, brooches, necklaces, in contact with the person, will become covered with mercury films during a course of hydrargyric treatment. Consistently with its vaporizable tendency increasing with heat elevation, warm baths help its passage through the sudoriparous channels, and it is well-known that nearer the tropics greater immunity is enjoyed from the effects of large doses. Indeed, the therapeutic dose could be regulated by geographic isothermal lines. The Hot

Springs, Arkansas, physicians attribute much of the success in specific ailment treatment there to the climate, which admits of larger doses of the drug. Now, if we take into account the climate and abundance of hot water in that locality, and reasoning that elimination of both mercurials and the specific poison, the evolution of which they assist, is thus greatly facilitated, we have a key to many of the cures effected there, and also to the reappearance of the disorder among those apparently cured who return north, where climate influence and failure to keep up the hygienic routine, so convenient at the Hot Springs, had closed the excretory passages upon abated, but still existing, disease.

As to the so-called "specific" reputation of mercury in syphilis treatment, and its *modus operandi*, I will not enlarge upon probabilities until syphilitic pathology is better understood. As the virus has a tendency to centralize upon and destroy certain areas, it seems likely that the metal may, by attacking such weakened points, not only break them down, but prevent the static degeneration necessary for recuperative processes. This, with the antagonism the metal has for occlusion anywhere except what it induces itself in great doses, suffices as a tentative view until the cause of the disease and its cure can be demonstrated. Syphilis may not manifest itself if sufficient globules are chasing it from forming nuclei; but where the fluids of the body are saturated with syphilitic points enough to produce tertiary symptoms, how futile must be any attempt to restore health by any doses of mercury. The disease itself is depleting the system at this stage, mercury but adds to the trouble, having more carious and degenerated spots upon which to work. At this period both syphilis and mercury will fraternize against the body as against a common enemy. Tonics might arrest the cachexia so induced, and in addition the iodids known to act both upon this disease and mercury should be given.

The article on the toxic effects of mercury in Ziemssen's *Cyclopedia* contains several mistakes as to the chemie and therapeutic properties of the metal, among which are noticeable the statement that hydrochloric acid acts upon mercury, and that calomel always salivates young children.

"Fürbringer," of Jena, has made a large number of hypodermic injections of metallic mercury, and states that at the time of the injection they are well borne, but within twenty-four hours inflammatory symptoms set in and frequently result in abscess. If mercury be simply injected and not divided by subsequent rubbing, it can not be found in the urine, but has been obtained as unreduced metal from under the skin at the end of a year and a half. However administered, a slow improvement of the syphilitic symptoms takes place. Metallic mercury is best borne when given in emulsion (Hg. 2.00, mucilage of acacia and glycerin $\bar{a}\bar{a}$ 10.00); one or two injections per week should be made. Fürbringer⁸ believes that the treatment of syphilis by mercurial emulsion injections should be reserved for cases in which inunctions and internal treatment fail, or in which it is not advisable to make frequent injections." I do not believe this method has a particle of advantage over mercurial inunctions well rubbed in. It is cited merely to show the identity of the results of mercurialization, how-

ever administered, and the fact that the mercury was not changed after a year and a half contact with subcutaneous tissue. The reason it was not fully absorbed was that division had not been effected between the particles of the mass.

Dr. F. N. Otis¹⁰ assumes syphilitic inoculation to consist of contact of a degenerate ameboid corpuscle, or disease germ, with the healthy human white blood corpuscle. The lymph spaces and channels convey this poison, multiplied in its course, to the general blood current. He cites Bäumlér¹¹ as virtually supporting the view that the characteristic feature of the active syphilitic cell is the possession of ability to set up in other cells through contact the same disposition to rapid proliferation. These cells *obstruct* tissues and undergo degeneration and elimination. Otis demonstrates that the syphilitic tubercle in common with all syphilitic sequelæ is a *deposit of arrested normal material*. He agrees with Bäumlér and Wagner, that "the favorite seats of these accumulations are in the subcutaneous cellular tissue, the skin, in and upon the bones, the liver, the testicles, brain, kidneys, and, especially in children, in the lungs. They occur as infiltrations of microscopic size scattered through the parenchyma of an organ." The causes of the accumulations, Otis claims, are the "*interferences with the lymphatic circulation*, the natural channels through which, according to Rindfleisch, the nutritive material exuded into the tissues in excess of the necessities of growth and repair is returned to the general circulation. *Luxurious new formations, catarrhs and secretions of all kinds, must be produced when the lymph conveyance is hindered.*" Rindfleisch says: "We will find this position in pathology very frequently confirmed." Dr. Otis emphasizes this matter of "*obstruction of lymphatic vessels*," and *hindrances to the lymph conveyance*," throughout his lectures, by italicizing as above.

Notwithstanding its aplastic properties, surgeons employ some mercurial before an operation, where the subject is syphilitic and there is likelihood of the disease complicating or retarding cicatricial growth. From the mechanical standpoint it would seem that they in such cases choose the lesser evil. The aplasticity of syphilis being progressive and destructive, while that of mercury abates, when the cause is withheld, or is even preferable to the fibrinous degeneration of syphilis. The percentage of fibrin is reduced by the increase of the watery secretions attending glandular activity. In this way mercury would be indirectly as well as directly opposed to plasticity.

Reverting to the observation that mercury attached to itself fine particles of dust, which were with difficulty separated therefrom, the behavior of the metallic globules in the physiologic channels may be justifiably compared to that of phagocytes. If a microorganism is eventually established as the cause of syphilis the antagonism of mercury for the disease may be found not only in its assisting elimination generally, but through phagocytic action of the globules in enveloping the morbid organism, as the wandering cells of the circulation are known to load themselves with bacteria, micrococci, etc. In this manner the adjacent tissues would be kept from infection and the globules of mercury could carry away, through emunctories generally, the microscopic cause of syphilis.

The therapeutic action of mercury is in the main mechanical. As water enters and issues from hydrants unchanged so mercury enters the body and leaves it plainly as mercury, and yet speculation has been rife as to some undemonstrable chemie change having occurred in transit, notwithstanding that the bodies of mercurialized animals have been repeatedly opened and mercury found in the various organs en route toward excretion or dormant in tissues. Salivation occurs through accumulation of the metal in the terminals of the dental arteries, a condition favored by the bony coverings of these arteries and their relationship with the carotids from which the globules pour over, to gravitate to the most dependent portions of the jaw; accumulation in the cancellated tissue, gums and salivary glands would fully account for ptyalism, the earliest effects being manifest in the lower incisors, those most apt, from their position, to be affected. Fournier observed that "mercurial ulcerations are situated always on the edges of the tongue, and on the side in which the person has been accustomed to lie when sleeping," further indicating gravitating tendency of the globules.

I shall now proceed to prove that *all the mercuric and mercurous preparations decompose in the body into mercury globules, the sizes of which determine much of their effects.*

Blue Mass.—Under a three-quarter-inch objective, magnifying seventy diameters. I placed the web of a frog's foot, and acquainted myself as thoroughly as possible with the peculiarities of its blood vessels, pigment granules, appearances by reflected and transmitted light, and then gave the frog five grains of blue mass. Twenty-four hours afterward I examined the frog, and found little globules of mercury mingled with the mucus excreted from its skin. Brushing these off, I placed its feet again under the same lens, and found blood vessels choked with metallic mercury; aneurysmal and varicose pouches were distended with mercury, and a great number of the so-called pigment granules had changed to a yellow metallic lustre; these spots reflected the light as would mercury, when examined by direct rays. As many as twenty of these lacunæ, or star-shaped bodies could be counted between two toes, and altogether there were about a hundred on each foot. The close resemblance between the lacunæ thus injected, and Stricker's description of the lymphatic sacs in the course of the lymphatics of the frog, led me to believe, at Dr. Lester Curtis's suggestion, that I had observed mercury in the lymphatic channels of the frog. Two little tubules choked with mercury presented a singular phenomenon. Under the power used the tubes appeared blind, but a little globule of unmistakable mercury lay upon the surface of the web at the outer end of one of the tubes. Watching this globule intently for ten minutes, it suddenly increased in size, and the tube collapsed, having emptied its mercurial contents outward. The globule thus formed was twice as large as the characteristic blue mass globule, and was easily removed from the web by a camel's-hair pencil. The other similar tube was more curved, and at its outer end had two such globules, both of which increased slowly in size, and in half an hour had grown very large at the expense of the tubular contents, the tube disappearing as did the first mentioned. Nowhere could I see anything like foreign particles *circulating* in the blood. The white and red blood corpuscles were distinctly visible, but in one capillary I found a small

¹⁰ Physiological Pathology of Syphilis.

¹¹ Ziemssen's Cyclopædia.

dark particle gradually accumulating similar particles near it: these I suspected were minute mercury globules: they accumulated against the current, and the blood passed around them freely: suddenly the down stream end of the mass broke away and apparently washed away in the blood out of sight. This was repeated several time while the mass, in this way, was proceeding up stream. While exchanging objectives for a higher power, the capillary cleared up. In one vein I observed plainly a large globule of mercury lying motionless, while the blood corpuscles beat against it with as little effect as water would have against a great stone in a brook: the corpuscles changed positions to pass it in the vessel, but slid by as rapidly as ever. Some of the exuded mercury globules on the web enabled me to obtain good comparative measurements. Six of these metallic spheres lay on the surface, just over one of the smallest capillaries. The six together measured the diameter of the capillary, and could easily have passed through this blood vessel abreast.

I repeated the experiment on a smaller frog by anointing the chin, axillæ, and thorax with Squibb's oleate of mercury, with the same result, only the large-sized globules were not so numerous. To a third (large-sized) frog I gave ten grains of blue mass, and as much blue ointment. I kept him in a glass jar, to be sure that he did not eject the pellets, and in this case, twenty-four hours after, found the lymphatic sacs engorged, but blood circulating undisturbed. In all the frogs so treated, where unavoidable lacerations of their feet had occurred in manipulating, there oozed from the torn edges minute globules of mercury. The last frog shed his skin in three days after the dose, but otherwise none of them underwent any apparent change in health or vigor. The skin, I think, must have afforded the main means of exit for the metal. There is not a fragment, however small, of this discarded cuticle which did not exhibit plainly the metallic globules attached to it in great numbers: many hundred microscopic slides might be mounted with the skin from this frog alone, and every slide will reveal fifty or more globules. In the dissecting room of Bennett Eclectic College of Chicago, a cadaver was exhibited to the students, the skin of which was so covered with mercury that an ordinary pocket magnifier revealed the countless globules. Dissecting the frog last mentioned, I found the stomach coated with the globules, but ten days having elapsed since the dose, no mercury was found between the intestines and the skin except in the dermis, but very probably in the liver. This organ was apparently choked with sacculations of an opaque substance, which at first Mr. E. B. Stuart and I took to be pigment granules, but after careful slicing by the microtome some sections one two-hundredths of an inch thick, and the opacity of those spots persisting, after careful consideration we regarded these opaque spots as aggregations of metallic mercury, held in the hepatic channels. In reflected light the unmistakable glint from mercury globules could be caught.

Hoping to discover the course of the metal through the frog's body, I administered a gram (15.4 grs.) of finely divided mercury, in albumin, to a male frog. In five hours globules appeared on its back. Dissection showed that the intestines, renal and portal circulation, heart, kidneys, and even the testes, contained numerous globules of mercury, and the lymphatic passages were beautifully injected with globules much

more finely divided. Apparently the lymph channels had chosen the lesser particles, or the metal had undergone further division in absorption into these passages. Biologists can profit by repeating my experiments and observe hitherto invisible animal channels which the passage of mercury demonstrates with even low magnifying powers.

(To be continued.)

DIPHTHERIA.

Read before the Harrisburg Academy of Medicine, Dec. 3, 1895.

BY W. H. SEIBERT, M.D.

MEMBER OF THE AMERICAN MEDICAL ASSOCIATION.
STEELTON, PA.

Diphtheria is an acute infectious disease, which, primarily, affects the mucous membrane of the pharynx, larynx, or air-passages; and, secondarily, as result of the absorption of the toxic element from the seat of infection, a general systemic or constitutional disturbance arises. The history of this disease dates back over many centuries, apparently beyond the time of Hippocrates, and all nations seem to have been scourged with its various epidemics at one time or other. It is notable that various theories were advanced to explain its causation, but it was only during the latter part of the present century, when with the improved teaching of the microscope and the advanced detail of laboratory technique, that the real cause was discovered and identified, namely, the Loeffler bacillus.

INCUBATION.

The period of incubation is the time which elapses from the deposit of the bacillus or germ on the mucous membrane, until some morbid phenomenon is manifested, and varies according to the susceptibility of the patient from one to several days.

SYMPTOMS AND COURSE.

The first appearance of the disease is generally on the most prominent part, as the tonsil, though it may be on the soft palate, the uvula, the posterior wall of the pharynx, the posterior nares, the nasal mucous membrane, or on any part of the mucous membrane exposed to the air. It is characterized by a false membrane or exudate, which varies in color from a grayish white to a yellowish brown or black. The affected part becomes red, swollen and tender, and rapidly becomes septic, and an offensive or fetid odor is emitted which gives rise to the name of "putrid sore throat" as a synonym for this disease. The membrane, at the start of the invasion, consists of simply a small, thin, whitish speck, which if discerned early may be speedily aborted by prompt local treatment and antiseptic precautions; but if permitted to progress the membrane becomes thicker, denser and darker, and spreads in all directions and gives rise to new areas of infection. The membrane has generally a well-defined margin, beyond which extends a considerable area of redness and the adjacent parts are much swollen and inflamed. The membrane adheres tightly and when removed it leaves a slightly depressed raw surface, or wound, over which the membrane rapidly reforms as large or larger than before, unless reparation sets in at this period. In some cases the erosion is quite deep and the mucous membrane seems to be in a state of necrosis or gangrene. The various glands of the neck, the lymphatic and salivary glands become much swollen, tender and

inflamed. There occur at times various extensions of the disease into the nares, the Eustachian tube, the lachrymal duct, the adjoining mucous surfaces, as of the cheeks, palate and alveoli, and on various denuded external parts. But by far the most serious extension is into the larynx, trachea and bronchi, giving rise to what is called diphtheritic croup. This usually occurs within the first week of the disease. Here we have the peculiar hoarse and croupy cough, difficult stridulous respiration, husky voice, dyspnea, and in advanced cases marked retraction of the larynx on inspiration. In some cases the infection starts in the larynx and in a day or two a patch of membrane is discovered in the pharynx, having apparently spread upward. Even no membrane may appear at all by ordinary inspection and thus leave in doubt whether really diphtheria exists, as in some cases of croup.

The secondary or constitutional disturbance is the result of the septic inflammation and the absorption of the toxin elaborated by the bacilli. In the mildest form there is a general indisposition to action, malaise, sometimes chilliness, and a temperature varying from 100 to 103 degrees F., which gradually subsides. In the severer forms these symptoms are magnified, and later when the system is overcome with the toxemia, great depression of the vital forces sets in and the patient has the appearance of being apathetic or indifferent to his fate. In the malignant form the vital forces are overcome by the sepsis from the onset of the attack and the above symptoms may or may not be present; the temperature is not high and soon becomes subnormal, the pulse is rapid, thready and quite weak, and the patient may even die before or within a short time of the discovery of the disease. Albuminuria is a pretty constant feature in most cases from the beginning, at least occurring within the first three days, and gradually subsiding as convalescence sets in.

The main sequel of diphtheria is paralysis of various muscles. This comes on gradually and generally about the second week of convalescence. The muscles most frequently attacked are those in proximity to the seat of infection, namely, those of the soft palate, pharynx and larynx, though various others as of the eyes, the trunk and the extremities, also become affected, and there is also for a time much general muscular weakness and inability of the patient to adapt himself to his usual exercise.

Diagnosis.—The diagnostic symptoms of diphtheria are few and in a general way dependence is largely placed on inspection, which, when a case is somewhat advanced and fairly well marked, is pretty reliable, and if the case occurs during an epidemic or in proximity to another case, it becomes the more certain, though it must be remembered that there are also some other processes which form membranes and are not diphtheria. In the milder forms, or very early in the severer forms, where but little or no membrane exists it is more difficult to distinguish from some other inflammatory processes as follicular tonsillitis and catarrhal inflammations of the pharynx and tonsils with ulceration. In the ulcerative process the covering is generally a secretion and readily removed and seldom gives rise to much glandular infiltration, the fever is more continuous, the fetid odor is generally absent, and convalescence begins in a much shorter time without the usual depression. The exudation of follicular tonsillitis is not so concrete or uniform as a diphtheritic patch, and it generally has the appear-

ance of having just oozed out of the follicles. Advantage can also be taken of the albumin test, as albuminuria is present early and pretty constantly in most cases of diphtheria and absent in the ordinary inflammatory affections. But for absolute certainty in any case, whether with or without membrane, the bacteriologic or culture test should be employed. In some cases of scarlatina it is difficult to differentiate, but here we generally have the peculiar eruption, the scarlet palate and fauces and later the strawberry tongue. The temperature is also generally higher and remains so longer than in diphtheria.

Prognosis.—The prognosis varies in different epidemics and at different times. There seems also to be a singularly higher death rate in some families than in others. In some epidemics the death rate has been as low as 10 to 15 per cent. and in some it has exceeded 50 per cent. It may be said safely that the diphtheria mortality has been about 40 per cent. In cases of ordinary severity, when seen early and where proper local treatment can be enforced, the prognosis is much more favorable than in the opposite state of things. Where the cases are severe and septicemia has advanced considerably before medical aid is summoned the prognosis is much less favorable, and where advanced cases have been neglected until marked depression has set in and where the patient is intractable to the treatment little is to be expected.

LOCAL TREATMENT.

In the treatment of diphtheria it is all important to keep in view the fact that it is caused by a specific germ which obtains effectual lodgment on the mucous membrane and in some manner sets up an inflammatory process, and a breaking down or necrosis of the affected part results; and further, that it is essentially a septic disease and by absorption of the septic element it produces grave local inflammations and most serious constitutional disturbances. The patient should be removed to an upper room where good ventilation and a proper temperature can be maintained. Having then here an abraded or raw surface, a wound on which is deposited a septic or toxic material, it becomes absolutely necessary to employ such means as will cleanse the affected part and render it aseptic. Cleanliness and antiseptics are the watchwords in the local treatment. The false membrane must be removed and the wound must be treated with an antiseptic and bactericide so as to render it unsuitable for the bacilli to thrive, as well as to prevent septic absorption and also to promote healing and restoration of the affected part. To remove the membrane I have found the peroxid of hydrogen a very effectual remedy. My mode of using it is thus: Some absorbent cotton is attached to a holder which is then dipped into the peroxid of hydrogen, which has been poured into a receptacle, and then gently applied to the false membrane with a rotary movement and slight friction, if the same is necessary to gradually accomplish its removal. Frequent changes of the cotton and the hydrogen are deemed advisable and some patience and time and repeated applications are necessary to obtain the best results. Thus the entire false membrane is removed by gradual and repeated applications. I then apply in similar manner the following lotion:

R.				
Tr. ferri chloridi	f3	i	30	
Alcohol vel listerin	3	i	30	
Hydrarg. bichloridi	grs.	ii		12
Menthol	5	i	4	

Being about 1-5 of 1 per cent. mercuric chlorid lotion, or 1 in 500 in strength, it may be applied thoroughly several times successively if the patient will endure it, though sometimes, as in infants, it is better to dilute it to half strength. In children there will be some struggling, and at times vomiting occurs, but the good results more than compensate for its unpleasantness. The patient, if able, is urged to gargle freely and frequently with the same lotion diluted to one-fourth or one-sixth this strength, and also previously with the peroxid of hydrogen diluted to one-half or one-fourth its strength. The attendant is urged to apply the hydrogen followed with the mercuric lotion every two hours. I have had excellent results with this local treatment and where it can be employed early and thoroughly good results can always be realized. I have seen the most severe cases, with the exudate or membrane covering the entire pharynx, improve the second day and gradually progress to recovery. Various other agents have also been used, as pepsin, trypsin, carbolic acid, hydrochloric acid, argenti nitras, cupri sulphas, etc., to remove the exudate. The chief object, however, in local treatment is to cleanse the part and render it aseptic. Cleanliness must be maintained all the time. The most danger lies in the sputa and mucous secretions and these should be disposed of in an antiseptic manner so as to prevent further infection. The hydrogen can be used to advantage at times by the spray as in the nasal and laryngeal forms. Here a dilution to 50 per cent. of its strength is preferable. I have also used listerin with very marked advantage by syringing, in full strength, in the nasal form. In this form upon the slightest appearance frequent syringing or spraying should be employed with the peroxid of hydrogen, the mercuric lotion diluted to one-sixth its strength, or listerin full strength or diluted one-half.

SYSTEMIC TREATMENT.

The constitutional or systemic treatment should be based largely on the existing indication, keeping in mind at all times the septic or toxemic nature of the disease, and its tendency to destroy life by gradual devitalization or lowering of the vital forces. Thus there may exist early good reason for the use of tonics, stimulants and reconstructive agents, as well as the most nourishing and persistent diet possible. If the fever is excessive such remedies as will alleviate, though not permanently depress the system, should be used. And if the patient manifest much weakness stimulants should be employed early and continuously as long as indicated. There is, perhaps, no remedy more valuable than the tr. ferri chloridi, which can be given freely, though well diluted, say in doses of 20 to 30 minims every hour or two to adults, and to children in proportion. The mercuric chlorid is also a most valuable internal remedy in doses of one-fiftieth to one-hundredth gr. every hour, well diluted, and I have frequently given the two in combination with excellent results. The salicylates, hydrochloric acid, cinchona preparations and various other remedies have also been employed by some. It is necessary to institute active and at times enforced nutrition from the start of the disease, and much of the good results obtained by some practitioners is due to the enforced and persistent nourishment of their patients. Where nourishment can not be given per os it must be given per rectum, and surprising results are obtained by thus maintaining the strength until the food can

again be administered in the regular way. In the laryngeal form it is well to remember that the exudate or false membrane likely exists and yet may not be perceptible, hence the propriety of the above treatment supplemented with such additional remedies as are indicated. Here the antiseptics and bactericides are best employed in the form of atomization or spray. In cases where relief is wanting, intubation and tracheotomy should be employed at a reasonably early period in order to save life. The paralyzes are treated with tonics, strychnia, electricity and massage or exercise of the parts.

SERUM TREATMENT.

In addition to the above treatment, a most valuable therapeutic agent, the serum-therapy, has been introduced and pretty fairly tested. My experience with this treatment has been only in private practice, and consequently somewhat limited, but the results obtained in cases of more than ordinary severity warrant me in concluding that it is a most valuable addition to the treatment of this dreaded disease. It seems to me that when promptly employed it is capable of reducing the mortality at least 50 per cent. It is both used as a curative treatment during the course of the disease and also as a means of forestalling or immunizing, on the same principle as vaccination is employed to immunize, or prevent, or modify variola or smallpox. As a curative agent it should be employed as early in the attack as possible and at least within forty-eight hours of the onset in severe cases, and even earlier in all cases where it is possible. By its use early in an attack undoubtedly good results will be had, but where used late in the attack, or when septicemia is considerably advanced and cell destruction has set in and prostration is grave, little can be expected of this remedy. It seems to be of marked utility also in the laryngeal or croupous form, and it is probable that its merits will be largely determined from results obtained in this form of the disease. I have had a very favorable result in a pharyngo-laryngeal attack of the severest type, in which on the second day of the attack the entire pharynx was covered with a black, tough membrane extending into the larynx and causing a most distressing attack of croup. Here the serum was employed about the thirty-sixth hour of attack of the disease, and about the twenty-fourth hour of the croup, and within twelve hours slight improvement in the respiration was noticeable, when another application was made and the case gradually progressed to a final recovery though the paralysis was extreme and very persistent.

Prophylaxis.—In the prevention of this disease it should be remembered that it is highly contagious, though it is regarded to be so mostly at close range and not at a great distance, like measles and various other contagious diseases. The greatest danger arises from direct contact with the sputa, the membrane or secretions. Complete isolation should be enforced and the persons exposed to the contagion should be quarantined, or separated from healthy or unexposed persons until danger of contagion is passed. Very much can also be done by enforcing hygienic regulations about the premises and localities as it is not unusual to trace sporadic cases to bad drainage and imperfect sewerage. It is also well to employ antiseptics and disinfectants about the premises and the probable source of the contagion. It is also well to have persons about the infected premises,

and especially those coming in contact with the affected parties, to gargle freely with a mercuric lotion of the strength of 1 in 4,000 to 5,000, and also to disinfect the clothing. It is also necessary, after convalescence is complete, to rigidly disinfect the premises, as the contagion may linger a long time, and thus be a menace to healthy persons.

RUPTURE OF SAC AND DEATH OF FETUS IN ABDOMINAL PREGNANCY AT FULL TERM. IMMEDIATE OPERATION WITH RECOVERY.

BY J. B. EAGLESON, M.D.

A. A. SURGEON, U. S. MARINE-HOSPITAL SERVICE; SURGEON TO SEATTLE GENERAL HOSPITAL.

The following case of abdominal pregnancy is reported as it presents some points of interest which are different from the few cases of this kind previously recorded.

Mrs. B. is 36 years of age, and American born from German parentage. She is of slender build and rather under medium height. She was married at 18 and has a daughter aged 17. At the birth of the daughter both cervix and perineum were severely lacerated, causing her considerable trouble until they were operated on some five years later. After the repair of the laceration she enjoyed excellent health, with regular menstruation, until the beginning of this pregnancy. She menstruated last on March 21, 1894, but as the flow at that time was of short duration and very scanty, it is very probable that the pregnancy really began one month earlier. With the exception of the morning sickness her health continued quite good until May 13, when she had severe uterine and abdominal pains accompanied by profuse hemorrhage, which continued for four or five days. During this flow a membranous cast of the uterus was expelled and the attending physician thought that she had aborted, and that the fetus had escaped notice. At this time there was quite well marked tenderness over the right ovarian region. She improved in general health and was quite free from pains for three weeks, when they returned on the right side, being more acute in character than during the previous attack, but unaccompanied by hemorrhage. The temperature was but slightly elevated. A bimanual examination revealed an enlargement to the right of the uterus, which was variously diagnosed as a cyst, an hematocele and a malignant growth. The severe symptoms subsided after a few days, but slight attacks of pain returned at frequent intervals during the summer. About the middle of July she began to feel what she thought to be fetal motion, and the husband, who is a retired physician, concluded that they must have been mistaken about the occurrence of the abortion in May. Later on he was able to feel distinct movements of the child, and could at times make out the extremities through the thin abdominal wall. He also felt confident of having heard the fetal heart on one occasion. She was fairly comfortable, with the exception of occasional attacks of pain during the latter part of summer and autumn. Some tenderness remained on the right side and during the last few months she was not able to sleep on that side. The child always occupied a position on the extreme right and low down in the abdominal cavity.

I was first called to see her on the afternoon of Nov. 11, 1894, and found her suffering from quite

sharp pains, which had been gradually increasing for several days. An examination revealed a small cervix situated high up against the sacrum almost out of reach of the finger, and the child was in a transverse position to the right of the median line. As the os had not begun to dilate I concluded that the pains were probably false, and gave her a $\frac{1}{4}$ grain of sulphate of morphin hypodermically in order to give her some rest, she having slept but little during the previous night, and advised its repetition sufficiently often to keep the pains in check, thinking that the position might right itself if she went to full term, since I had been informed that she was but about eight months pregnant at this time. The husband stated that he had found some albumin in the urine the day before, and I

Sac of placenta showing rupture through which child was extracted.

found a sample sent to me later in the evening to be very dark colored and to contain about 50 per cent. of albumin by volume. The feet and legs were considerably swollen, especially the left one. Milk diet and Basham's mixture were advised. I did not see her again until the next evening. She slept some during the night and had been comparatively free from pain during the day. The patient remarked that she had not felt motion for several days and feared that she would have a stillbirth. While I was examining for the fetal heart with the stethoscope she went into a very hard convulsion, which was checked by chloroform inhalation, and while she was under the anesthetic I again made a careful examination, but did not succeed in finding the fetal heart.

Realizing that the case was a serious one, a consultant was sent for, but before his arrival she had a second convulsion, and then a third during his examination. At this time the abdomen was very tender and quite tympanitic. The temperature was 101.2 with a pulse of small volume at 112. It was decided that rapid dilatation and immediate delivery was imperative. Under complete anesthesia, my hand was introduced into the vagina and the cervix dilated, but much to my surprise I found my finger in the cavity of an empty uterus scarcely above normal size. It was now evident that we had to deal with an extra-uterine fetus. Owing to the uremic convulsions and commencing peritonitis it was decided to operate at once and she was removed to Providence Hospital, where we operated two hours later. I made a median incision and came down upon a large placental mass just above the bladder. The sac was not adherent to the abdominal wall, but had ruptured and the fluid part of the contents had escaped into the abdominal cavity setting up a mild general peritonitis. After a careful search the opening in the sac was found on the left side of the placenta. On introducing the fingers into this the feet were at once reached, and by enlarging the opening the child was extracted through it. The position of the child was on the patient's right, with its right side toward the right, the legs extended across the abdomen and head turned extremely to the left and pushed up under the right lobe of the liver. It had been dead several days as the cord was somewhat shriveled and the skin was macerated. It was a well-formed female child weighing six and three-quarters pounds. There were no adhesions of the sac to the abdominal wall and but few to the intestines, which with two or three exceptions were easily peeled off without the use of ligatures. The placenta was quite firmly attached to the top and posterior surface of the uterus, and to the right broad ligament. But few vessels had to be tied. The principal nutrient vessel of the placenta, which was almost the size of a lead pencil, came from the under surface of the mesentery of the ileum. But a small quantity of blood was lost during the operation. The peritoneal surfaces presented evidences of commencing inflammation.

The abdominal cavity was thoroughly washed with hot boiled water until it came away perfectly clear. A large glass tube was inserted down into the cul-de-sac in the center of a gauze drain. The abdominal wound was closed by kangaroo tendon sutures for the peritoneum and fascia, with silkworm gut for the deep sutures through entire thickness of the parietes.

The patient was stimulated by rectal enemata of hot beef tea and whisky, with digitalin and strichnia, and by morning she had rallied from the shock nicely. The glass tube was removed on the second day and the gauze drain the fourth day, after which the wound united by first intention and the recovery was uninterrupted. The day following the operation the urine contained 75 per cent of albumin by volume, but this gradually diminished until there is now but a slight trace present. There were no more uremic convulsions after the operation.

For the Prevention of Blindness in Pennsylvania. In order to prevent blindness, a law was passed by the Legislature of Pennsylvania in 1895, which imposes a duty upon all midwives, nurses or other persons having the care of infants, and also upon the health officer, and fixing a penalty for neglect thereof.

ELEVEN YEARS OBSERVATION IN THE USE OF CREASOTE, IN THE TREATMENT OF TUBERCLE OF THE LUNGS.

BY J. O. COBB, M.D.

P. A. SURGEON U. S. MARINE-HOSPITAL SERVICE.
CINCINNATI, OHIO.

For eleven years I have had a greater or less number of patients constantly under observation with the creasote treatment, and feeling the importance of the subject and the general interest taken in this disease, I have been led to report my experience. A large majority of patients have been seamen of the merchant marine. The conditions noted cover all stages of the disease.

The places of observation were South Carolina, Texas, different stations on the Great Lakes, a few cases at Evansville and St. Louis and the remainder at Port Townsend, Washington.

A majority of the cases were not diagnosticated by bacteriologic examination as physical methods easily revealed the condition. All cases of "chronic pneumonic phthisis," "chronic pneumonia," etc., are excluded.

Pure beechwood creasote was given throughout. Dosage ranging from one to seventy minims, has been tried. Some cases have been treated to a termination with a few minims given constantly and without variation. Others were given gradually increasing doses until the limit of toleration was reached, when the drug was recommenced at the small dose to be again carried to the limit of toleration. Still other cases were given gradually increasing doses to the limit of toleration then decreased to the point of toleration and kept there to the end of the treatment. Some of the cases had other treatment in conjunction, though the large majority were treated exclusively with creasote.

The serious objection to creasote is the unpleasant, sickening and burning sensation which it causes in the stomach. I have used the pure creasote made into emulsions, mixtures, pills, etc., none of which were at all satisfactory. The best method that I have found is to nearly fill a gelatin capsule with pulverized acacia, drop in a few minims of the creasote and take at once. If the dose is to be large this is a very bothersome way to give the drug. I have prescribed carbonate of creasote to a few private patients but the period of observation has been short and unsatisfactory; however, I think this a desirable way to give the drug. I have also given the drug by inunction but not with satisfaction. Patients show greater and quicker improvement from the treatment in a warm dry climate and the dosage is smaller.

If there be tuberculous infection of the kidneys, the general condition will be aggravated by giving the drug in any dose. My patients with high fever did not do well, probably on account of irritable stomach. Valvular heart disease does not interfere with the results of the treatment. Tubercular infection of the intestines and mesenteric glands is benefited by the treatment, though the point of toleration is lower. I have had no experience with tubercular meningitis. Tuberculosis of the bones and joints received no benefit. I have had no experience with the drug in the treatment of children. The age of the adult does not seem to make any difference. The treatment may bring on complications such as

severe headache, injection of conjunctiva, lachrymation, the sensation of constriction of the chest which soon passes off, bloody urine, indicanuria, transitory glycosuria, increase of the daily amount of urine, nervousness and disturbed slumber, a rash, and last and most serious and which is nearly always the final and fatal complication, pneumonia. It is especially dangerous to give the drug when there are kidney complications. When there is high temperature it does no good. With the complication of pneumonia it is absolutely dangerous. Pulmonary hemorrhage is rapidly improved. Prolonged administration causes severe and harmful anemia. If the test for blood or indican in the urine shows either to be present the drug should be discontinued at once. The treatment is of little avail when there is sapremia due to absorption from large cavities that have become infected with pyogenic bacteria. Small dosage with creasote is not beneficial; the only positive results obtained have been from a very liberal administration. Hopefulness led me to think many of my cases cured, but in nearly all, the disease has recurred. It has been impossible to follow all of these cases though a few report to me at stated intervals. I doubt that a single case has thus been cured. In comparison with other drug treatment creasote has given me the only satisfaction, however scant, obtained.

Large dosage with creasote given constantly at the point of toleration is dangerous for the following reasons: After continued administration for a great length of time, the patient becomes very anemic, from which trouble he rarely recovers; secondary infection of healthy lung tissue takes place from detached necrotic tissue producing a rapidly fatal pneumonia. Many of my cases on the large dosage have improved very rapidly and were thought to be nearly well. They have been exhibited to medical friends with much enthusiasm with the hopefulness that the cure would be permanent. Many of these patients would rapidly succumb to pneumonia probably a short time afterward. For a long time I thought the pneumonia to be only an accidental complication but I now feel convinced that the treatment is the cause, due to secondary infection with necrotic tissue as mentioned above. Finally I must state that I believe that no well marked case of tubercle of the lungs recovers with the creasote or any other drug treatment without the very best and most favorable climatic conditions coexisting with the treatment.

ON THE DIAGNOSIS OF GASTRIC ULCER.

Read before the Chicago Medical Society, Oct. 7, 1895.

BY L. HARRISON METTLER, A.M., M.D.
CHICAGO.

A disease that causes no less than 5 per cent. of all deaths and that can only be "approximately" diagnosed in the absence of hematemesis is still deserving of the closest study. The following case is presented as a text for a discussion upon the hitherto known signs of gastric ulcer.

N. H., aged 27, first came under my observation Nov. 29, 1893, through the kindness of Drs. Lyman and Ward, after a profuse hematemesis. Neither the family history of the young woman nor that of her early life presented anything of special note. Having somewhat of a neurotic type of constitution, she nevertheless has always borne the appearance of fairly good health, being well nourished and well developed. She has always been of a studious turn of mind and devoted much time

to music and literature. She is fond of outdoor sports and is an expert bicyclist. Except for a slight degree of paleness, one would never look upon her as in any way an invalid. There were no pulmonary or cardiac symptoms. Menstruation began at 15 and has always been regular, painless and scanty. Amenorrhea occurs at times. There is a tendency to constipation. About eight years ago she began to be troubled with dyspepsia. At that time Dr. Birdsall, of New York, treated her for anemia, which treatment she continued irregularly for five years. For her dyspepsia she consulted Dr. Vaughan, of Ann Arbor, quite a while ago, and he assured her then that she did not have gastric ulcer. Several physicians have diagnosed her case at various times as nervous dyspepsia and she has been almost continuously under treatment for this condition. Her appetite had always been good but she learned the necessity of being careful in the selection of her food. Near the cardiac end of the stomach she has had at times a slight gnawing or boring pain which shot through to the back and was felt near the angle of the left scapula. Sometimes after partaking of solid food the pain would become very acute and definitely localized so that she could easily cover it with a half-dollar coin. There was almost always more or less pain in the left hypochondrium, and its site never shifted anteriorly or posteriorly. Sometimes, she says, it feels as though a grape seed or other small, pointed object had gotten fast in the left side of the stomach. In the intervals between the taking of food, she feels as though the stomach were contracting or that its lining were forcibly drawing together. She suffers from occasional headaches, due probably to the anemia, but otherwise she is perfectly free from neuralgic pains. Three or four severe "fainting spells," about a year apart, have caused her considerable alarm. In them she became decidedly cyanosed and remained semi-conscious for a brief time. They always left her very weak. In one of these "spells" she fell completely dazed from off her bicycle. I can obtain no more definite history in regard to these attacks of syncope, as they occurred mostly when she was alone and closely engaged in some occupation. Their after-effects were vouched for by friends and relatives. It never occurred to her to notice the character of the stools immediately after them, as she supposed they were due probably to "biliousness" or "nervous weakness." There is a possibility that they may have been the result of small internal hemorrhages, which gave no other indication than that of mild shock. She does remember, however, that right after these spells the stools were somewhat looser than usual. She has frequent attacks of nausea, and though the appetite is good, food frequently produces a feeling of repugnance. There has never been any vomiting.

On Nov. 27, 1893, a severe hematemesis occurred, the first she had ever had. Members of the family declared it amounted to nearly two quarts of blood, probably an exaggerated estimate made in the excitement of the moment. The blood was described as very dark in color and full of small clots. This so prostrated the patient that she fell to the floor and was put to bed in a dazed condition, nauseated and completely exhausted. Menstruation began upon the following day and still more weakened her physically. The pain in the hypochondrium suddenly became much worse and was experienced most keenly on the left side and under the angle of the left shoulder blade. There was an intolerable headache. The temperature was not elevated and the pulse became subnormal. Just before the hematemesis the bowels had moved very freely, almost to the extent of diarrhea. They were noticeably dark in color. She had just been taking for her dyspepsia ten drops of dilute hydrochloric acid. Dr. Ward saw the case immediately after the hemorrhage and administered ergot, cracked ice, cold drinks and one-sixtieth of a grain of strychnia every four hours. Such was the history of the case related to me when I first saw it two days later, Nov. 29, 1893, at the urgent request of Dr. Ward, who was preparing to leave for California. I found the girl in bed, pale, with an anxious expression and complaining of the sharp burning pain in the stomach. Lying upon either side made the pain more acute. Not knowing what diagnosis had been given, I at once told the parents that, in my opinion, it was a case of gastric ulcer. Absolute quiet in bed was enjoined and all visitors positively forbidden. A drachm of milk and lime water or matzoon was allowed every hour. There was no vomiting when I saw her, so that I had no opportunity of examining the contents of the stomach and the passing of a tube to secure a sample of the gastric juice was entirely out of the question. A week later patient was still very dizzy and nauseated when she injudiciously attempted to sit up in bed. The bowels had moved twice, once normally and once after an enema. Both times they were quite normal in color. The headache continued to be dull and constant. The localized pain in the left hypochondrium did not abate but radiated

up along the left side and behind the sternum. It was also very acute posteriorly. At this time one ounce of matzoon, or milk and lime water, or a little of Leube's beef solution was taken every hour, according to the patient's taste. Three times a day she also took a drachm of the juice of pressed, slightly broiled beef, as well as one-sixtieth of a grain of strychnia. Beyond the dietary mentioned the slightest increase brought on sharp pain, nausea and a tendency to vomit.

On December 7 the strychnia was withdrawn and one drop of Fowler's solution of arsenic administered three times a day.

Up to December 20, when for the first time I permitted the patient to sit up in bed for a few minutes, there was nothing of special importance in the progress of the case. Once or twice a slight excess of nourishment came near precipitating an attack of vomiting. Pain and nausea continued but were very noticeably diminishing. Hemoglobin compound (P. D. & Co.) was added to the treatment to restore the loss caused by the hemorrhage. On December 27 the patient began to dress and recline awhile each day in a large arm chair. On Jan. 4, 1894, she commenced taking solid food in small quantities. There was no nausea now, very slight pain and only an occasional ache in the region of the cardiac end of the stomach. There was still much weakness with some shortness of breath. The strychnia was again added to the treatment. After January 7 she began to go downstairs each day and cautiously resumed her usual occupation. Convalescence was rapid and satisfactory. Carlsbad salts and ferruginous tonics terminated the special medication.

In February the patient went to Florida, spending several weeks there, greatly to her benefit, eating heartily, bathing in salt water and living an outdoor life. She returned April 3, the picture of health and having gained twenty pounds in weight. She was then quite free from all suffering. In August, 1894, she was married, and has since given birth to a healthful child. During pregnancy there was no vomiting of any consequence but considerable nausea. Occasionally now some indiscretion of diet will bring on an attack of nausea and revive the acute lancinating pain which shoots through to the back. It does not last, however, and it quickly disappears with a return to liquid or semi-solid food. There is a marked tendency to constipation, but carelessness in regard to eating precipitates a sharp attack of diarrhea. In all other respects the patient appears and feels perfectly well.

There are two kinds of ulcer of the stomach, the diagnosis of which is either impossible or unimportant. The one is the latent ulcer which runs its course without symptoms, and is recognized merely as a post-mortem curiosity; the other is the ulcer which remains latent until a sudden, rapidly fatal hemorrhage renders its diagnosis of retrospective interest only. As clinicians, the form of ulcer which concerns us most is the variety having more or less definite symptoms. Of this variety there are the *suspected* ulcers, the diagnosis of which can never be more than approximate and the *recognizable* ulcers, of which we can form a reasonably positive diagnosis.

The cardinal symptoms of gastric ulcer are, in the order of their importance, gastrorrhagia (hematemesis), pain of a peculiar sort, dyspepsia, hyperacidity and vomiting. Given all these symptoms in any one case and we may be assured that ulceration of the stomach is present. Of these five cardinal symptoms gastrorrhagia is by far the most important, for until there occurs a hemorrhage, large or small, from the stomach, the other symptoms can only lead us to a suspicion of ulcer. The variable importance attributed to these other symptoms is the ground upon which clinicians differ most in their diagnosis of Cruveilhier's malady. It is extremely desirable that more unanimity of opinion should obtain in regard to the value of these symptoms or that new ones should be discovered which would foster uniformity of diagnoses by reason of their greater exactness. These symptoms arranged in the order of their frequency are epigastric pain, vomiting, indigestion, hyperacidity and gastric hemorrhage. Constipation, anemia, chlorosis, amenorrhea, the red tongue of Niemeyer, the local hyperthermia of

Peter and Hayem, the gastric contraction and dilatation of Gerhard and the associated cachexiæ are all so variable as to be of less importance as diagnostic signs than the etiologic factors of age, sex and occupation. I will consider, therefore, for a few brief moments the relative value of the cardinal symptoms of gastric ulcer, namely, the pain, indigestion, hyperacidity, vomiting and gastrorrhagia.

Everybody knows that a dull, lancinating, burning and gnawing pain, strictly localized near the epigastrium, shooting through to the back and appearing with peculiar distinctness near the angle of the left scapula, occurring at times in severe paroxysms, increased usually by food and external pressure, and more or less modified by posture is almost pathognomonic of gastric ulcer. I can not recall a case diagnosed ante-mortem as ulcer, in which pain was entirely absent. It is a marvelously uniform and correspondent symptom. Pain, however, is always an unsatisfactory indication upon which to base a diagnosis, and in gastric ulcer it would probably be one of the least valuable, were it not for its constancy. Its fixed nature and relative constancy are its preëminent characteristics. Even the steady discomfort of gastrodynia can usually be temporarily relieved by a small blister over the site, but not so the peculiar pain of gastric ulcer. I believe, therefore, that its constancy with one or two peculiar features, which it always manifests, raises it to the position of a most valuable diagnostic sign. It is very exceptional for this pain to be continuously absent throughout the entire course of the disease, and a careful study of its character ought, it seems to me, to furnish, when present, the strongest kind of a suspicion of ulcer. Occasionally the pain is modified so as to render a differentiation of ulcer from gastralgia, cancer, chronic gastric catarrh and the gastric crises of Charcot a matter of some difficulty. But if one has an opportunity to observe his case for a time, I think he will be able to determine the cause of the pain. Gastralgia is met with in chlorotic and hysteric females, is independent of the ingestion of food and is not fixed; it is not relieved by vomiting, but is often caused to vanish by external pressure; it is entirely absent in the intervals between the paroxysms and it is benefited more by electricity and general tonics than by the regulation of the diet. Other well-known symptoms usually accompanying cancer, chronic gastric catarrh and the gastric crises of certain organic nervous affections are adequate for a differentiation. It should be remembered, however, that ulcer is always accompanied by chronic catarrhal gastritis. Thus the pain of ulcer during a paroxysm may resemble the pain of gastralgia and in the intervals between the paroxysms, resemble that of chronic catarrh; but in such a dilemma it is safer to conclude that the disease which can give rise to both gastralgic pains and catarrhal soreness is present than that the patient is the victim at one and the same moment of two such dissimilar affections as chronic gastritis and nervous dyspepsia. I do not believe it is possible to diagnose the site of the ulcer, as Brinton teaches, by the location of the pain, by the manner in which it is affected by posture or by the mere ingestion of food. Peripheral pain is never uniformly situated when due to an uncertain, deep-lying lesion, and on the other hand patients assume all sorts of bizarre attitudes in their efforts to get rid of their agony.

Next to pain, vomiting is probably the most fre-

quent symptom of gastric ulcer, but unfortunately it is so commonly associated with other troubles that it is perhaps the least important in this. Its only value here lies in its association with other signs. Unlike pain it alone would never lead us to suspect ulcer. There are certain cases of ulcer in which vomiting is the most marked and distressing symptom, but unless the vomited matter contains blood or it is associated with several other characteristic symptoms, it is a perfectly useless indication of ulcer. It has been said that the vomiting of "mucus or of a thin fluid unmixed with food" is indicative of only chronic catarrhal gastritis, and that "alimentary vomiting" is always suggestive of gastric ulcer. I think I have seen alimentary vomiting more than once in chronic catarrhal gastritis, and moreover, catarrhal gastritis is almost invariably a complication of ulcer. Not infrequently the victim of ulcer experiences an intensely sour taste from the matter vomited, and this leads me to the consideration of the next symptom, hyperacidity.

In regard to the pathogenesis of gastric ulcer, the theory of the self-digestion of the gastric mucous membrane has had, and still has, many advocates. Whether the theory be true or false, it seems to be a fact that the hydrochloric acid of the stomach is in excess in a large percentage of the cases of ulcer. According to Korczynski and Jaworski,¹ it is greatest at the time of hemorrhage. Some declare that the excess of digestive fluid results from the irritative action of the ulcer itself, others that it precedes and originates the ulcer. Riegel, who has studied this symptom most exhaustively, says that the proportion of hydrochloric acid in the stomach of a case of chronic gastric ulcer is 0.4 to 0.6 per cent. as against 0.1 to 0.2 per cent. in health. Ewald's words are: "I regard the demonstration of increased acidity as a marked advance toward the recognition of this condition and it enables us to make an early diagnosis." Hence, hyperacidity, when present, becomes a valuable sign of gastric ulcer. I say advisedly "when present," because it sometimes happens that in the progress of the ulcer the acidity of the gastric juice diminishes to normal or even below normal. This has frequently been demonstrated by Ewald, Ritter and Hirsch and Jaworski. According to Lenhartz the acid may even be deficient in gastric ulcer. After reporting a case in which the percentage of acidity was far below the boundary line, Ewald remarks "that hyperacidity is not an absolute attribute of ulcer of the stomach and that a negative result is accordingly not decisive in establishing a diagnosis."² Furthermore, as ulcer is not infrequently associated with cancer, it may happen that the more pronounced manifestations of the ulcer will be accompanied by total absence of hydrochloric acid. Such association of ulcer and cancer occurs, according to Dietrich, in 5 per cent., according to Rosenheim in 8 per cent. of all gastric carcinomas. In these cases hyperacidity may continue with the growth of the cancerous tumor, or it may diminish. Unfortunately, we can not always obtain this valuable support to our diagnosis, the symptom of hyperacidity, even when it may be present. In many cases of ulcer there is no vomiting, not even nausea; and as soon as ulceration is suspected the passing of a tube into the stomach for the purpose of securing a sample of the gastric juice is regarded by most clinicians as too hazardous to pay for the

meagre information likely to be obtained. For this reason Leube omits the acid test when he thinks he has a case of gastric ulcer. Germain-Sée disapproves of lavage and the use of the tube in such conditions since Cornillon and Daguet have both reported fatal hemorrhages from such maneuvers.

It has been shown by Schreiber and Pick that catheterization of the stomach, however gently performed, invariably produces an immediate and rapid outpouring of secretion from the gastric glands and that only after many trials does the viscus become tolerant enough to retain during such manipulation its wonted production of digestive fluid. In addition to this it must also be remembered that we can only diagnose hypersecretion, according to Vierordt, when by a rapid and careful procedure at least 200 c.c. of acid gastric secretion are obtained. All of this goes to show that those cases of ulcer in which the symptom of hyperacidity, however valuable it may be, becomes available are not very many. It is of some practical use, however, to notice that the state of the urine is more or less complementary to that of the gastric juice; for with the increase of acidity of the latter there is in the former an increase of specific gravity, diminution in quantity and loss of acidity. Alkalinity of the urine and a decrease or absence of its chlorids are bad prognostic signs.³ With the increase of hydrochloric acid in the stomach there are also such general symptoms as thirst, heartburn, pain at night and acid vomiting. As a matter of differentiation it is to be remembered that in acidity occurs in gastric cancer, dilatation produced by an ulcer scar at the pylorus, in severe anemia, various fevers and simple nervous dyspepsia with or without gastralgia.

Indigestion on account of the associated chronic gastric catarrh, must obviously be a frequent symptom of gastric ulcer. As the indications of catarrhal dyspepsia are so familiar to all, they need not be detailed here. With all its train of objective and subjective manifestations, indigestion is not an altogether worthless symptom of ulcer, because in the first place it is almost constantly an accompaniment of ulcer and in the second place when constituting the general background of the picture in which appear one or more special symptoms of ulcer, it immensely strengthens the diagnosis. There is nothing peculiar about this indigestion except its persistency and conjunction with the other suspicious signs of gastric ulcer.

I have thus far referred to the more ordinary signs of ulcer, and I fully believe that if they are carefully studied in every case they will afford us more than a mere suspicion of the disease. The symptom, however, which completes the picture and gives precision to the diagnosis in the majority of well-defined cases at least is gastric hemorrhage. Out of seventy-two cases of hematemesis, forty resulted from gastric ulcer, according to Handfield Jones,⁴ Lebert noted gastric hemorrhage in four-fifths of his cases, and in three-fifths of them the hematemesis was profuse. Brinton estimates that large hemorrhages occur in about one-third of all cases; according to Müller's analyses it occurs in one-fourth of the cases. Gastrorrhagia is sometimes the only symptom of ulcer, such cases being of the latent variety and quickly terminating fatally. They are the *ulcères foudroyants* of the French authors. I believe that gastric hemor-

⁴ Med. Chi. Transactions, vol. XLIII.

rhage occurs more often than is generally supposed, but that it is so slight as to pass off unnoticed by way of the bowels. I imagine that something of that sort may have caused the various fainting spells referred to in the case which I have reported.

Some authorities state that in gastric ulcer a hemorrhage sometimes occurs regularly as vicarious menstruation. Aside from their being but little foundation for such an opinion, I believe it would be dangerous for the patient and confusing to the diagnosis to so regard such hemorrhages. The irregular catamenia, especially the amenorrhea so common in these cases, are not the cause of the hemorrhages so much as the result of the debilitated constitution brought about by the loss of blood. A periodic hemorrhage in gastric ulcer is not menstrual but rather a gastrorrhagia accompanying the ulcer and provoked by the monthly disturbance of the system. If the hemorrhage is large and recent the blood will be bright red in color, alkaline, fluid and mixed with food and mucus. More frequently, however, it is retained long enough in the stomach to be acted upon by the gastric juice. It will then be more or less clotted, having the appearance of coffee grounds, changed in color to dark brown by the changing of hemoglobin into hematin, acid, unacrated and minutely intermingled with particles of food and sour mucus. Hematemesis occurs in many diseases and must always and especially be differentiated from hemoptysis.

In conclusion then, I believe that gastric ulcer may be strongly suspected where there is the peculiar pain already described and hyperacidity; and if to these be added gastrorrhagia, the diagnosis may be made with gratifying certainty. I have purposely refrained from considering the indications of the site of the ulcer, which in cases of perforation may be surgically important. My only object has been to emphasize and assign the proper valuation to each of the cardinal symptoms of gastric ulcer, symptoms upon which alone anything like a positive diagnosis may be based.

Columbus Memorial Building.

OBSERVATIONS AND STATISTICS UPON THE USE OF ANTITOXIN IN ONE HUNDRED CASES OF DIPHTHERIA.

BY ROSA ENGELMANN, B.A., M.D.

PROFESSOR OF PEDIATRICS IN THE POST-GRADUATE MEDICAL SCHOOL OF CHICAGO; FELLOW OF THE CHICAGO ACADEMY OF MEDICINE; MEMBER OF THE CHICAGO HEALTH DEPARTMENT STAFF, ETC. CHICAGO.

The following observations, statistics and histories are offered as a contribution toward clearing up obscure and unsettled points relative to diphtheria and antitoxin.

It has long since been experimentally proven that the Klebs-Löffler bacillus produces a specific toxin giving rise to all the classic signs of diphtheria. The pseudo-diphtheria bacillus is supposed to be a non-virulent, attenuated or modified form of the former. The latter, the streptococcus longus, streptococcus pyogenes and staphylococcus are associated with the Löffler bacillus and cause pathogenic conditions, respecting which there is much to learn. For instance, such cases of croup, necessitating even intubation, in which these non-specific germs only could be grown in spite of repeated culture trials, have been relegated to the list of anomalous cases. Such an explanation, however, no longer satisfies the scientific world. More extended biologic research and study of serum-therapy

will doubtless change the nomenclature of a disease having such a multiple genesis and pathology. The minuter chemico-physiologic reactions of the diphtheria toxin and antitoxin upon the human cell and organism still require elucidation. Before proceeding to the tabulation of cases as observed by me in eight weeks' service in the health department, I will formulate the points that particularly impressed themselves upon my attention and later emphasize them by a recital of interesting histories. They are:

1. The marvelously rapid improvement, especially in the laryngeal or most dangerous form of the disease when antitoxin is properly administered, viz., early enough, in large enough doses and in frequently repeated doses in severe cases where but little improvement is noted within eighteen hours.

2. The necessity for early cultural diagnosis.

3. The clinical relation of the pseudo-diphtheria bacillus to the Klebs-Löffler bacillus and their mutual interchangeable attributes, such as virulence, benignancy, transmission, etc.

4. Bacterial, aborted or modified diphtheria without clinical manifestation.

5. Persistence of the Klebs-Löffler bacilli in the throats of these subjects in spite of rigorously applied antiseptic treatment.

6. Menace to the community as contagion bearers of these subjects; hence the need of isolating them.

7. Relative absence of post-diphtheritic paralysis despite the severe character of the epidemic.

8. Period of, and positive and partial immunity conferred by the use of antitoxin.

9. Contraction of diphtheria after immunization due to the tardy use of antitoxin.

10. Rashes and sequelæ consequent to the use of antitoxin.

11. Failure to demonstrate the Löffler bacillus in some undoubted cases of diphtheria.

These inferences have been reached by actual observation and care of the greater number of cases comprised in the following table:

Cases visited or seen, 137; curative antitoxin doses given, 102; curative antitoxin doses given by me and assistants, 72; curative antitoxin doses given by other physicians in my district, 30; recoveries after antitoxin, 95; deaths after antitoxin, 7; physicians asking treatment for their patients, 9; physicians giving this treatment, 20; cultures made for 250; laryngeal cases, 50; mild laryngeal (seen within first sixty hours) cases, 28; severe stenotic cases, 22; cases immunized, 166; cases completely protected, 150; partially protected, 16; bacterial not clinical cases, 28; deaths twenty-four hours after injection, 3; deaths later, 2; deaths in which antitoxin was not used, 5; cases of paralysis within twenty-four hours after use of antitoxin, 2.

	1st day.	2d day.	3d day.	4th day.	Later. day.	Unknown day.
Number of cases injected.	16	34	21	10	14	7
Recovered	16	33	20	8	11	7
Died	0	1	1	2	3	0

Intubations by others, 4; intubations by me, 1; total 5; tracheotomies, 1; cases of rashes consequent to use of antitoxin, 12.

The death, as reported after the use of antitoxin upon the second day of the disease, was in a laryngeal case of probably longer duration than reported. That reported as having received an injection upon the third day, received, to my knowledge, too small an initial and second dose, and besides had not been freely enough stimulated. One of the cases of paralysis was in my practice and was, I think, due to the profound toxemia and could not be ascribed to the action of the antitoxin, for the diagnosis was not made until the fifth day of the disease, or until stenosis set in and

when the child was pretty well poisoned. Seven deaths in 103 cases, of 6.97 per cent., is a very low death rate, especially if one considers that 50 of the 103 cases, or almost 50 per cent., were croup, the most dangerous form of diphtheria. Doubling this death rate to 14 per cent. for the laryngeal cases, still leaves a remarkably low mortality. This brilliant record is due to the fact that 91 of the 103 cases were injected within the first three days. This was accomplished by reason of a large dispensary clientele upon whom cultures were made and the rapid and hearty coöperation of those in charge of the municipal laboratory, whence the reports reached us in from fifteen to eighteen hours, to be immediately acted upon. It is to be regretted that inasmuch as this was an out practice, no evidence as to the effects of antitoxin upon the kidneys could be obtained. Such histories of cases will now be selected as characterize the points above noted:

Case 1.—January 13, I was called in counsel to see Babe S., age 11 months, who had been sick thirty-six hours. It had almost choked to death during the night, as the mother expressed it. The breathing was stertorous and the cyanosis, dyspnea and stenosis were extreme. It had been freely stimulated and given slaking lime fumigations and an iron and bichlorid mixture. There were small patches on the tonsils. The culture showed a few Löffler bacilli only, because of the use of the antiseptics above indicated. Fifteen hundred units of antitoxin was immediately given, with the injunction to repeat the dose in eighteen hours if the child was not much better. The temperature was now 101.4, and had risen to 104.6 when I called again at noon of January 14. I again injected 1,500 units and now advised intubation in order to tide the child over until the second dose should have begun to take effect. By evening the temperature had again fallen and the child was so markedly improved that the latter procedure was obviated. January 15 cyanosis, dyspnea and stenosis had entirely disappeared and the harsh, noisy respiration was the only indication of the recent trouble. The child was bright, smiling and playing with its rattle, in wonderful contrast to its forty-eight hours previous struggle for breath. Six hundred units more was administered in order to entirely clear up the remnants of membrane still evidently in the larynx; for the fauces were now clear. This child made a rapid and uneventful recovery without sequelae or complications.

Earlier in my experience with the use of antitoxin, I had not used it so boldly nor freely, and the cases had invariably progressed to the point where intubation and even tracheotomy were necessitated. I have likewise noticed that in the late cases where tubes were worn and antitoxin freely given, the former were expelled or removed early and sometimes repeatedly, because of the rapid sloughing of the membrane.

The advisability, yes, indispensability of an early cultural diagnosis, the intimate connection of the pseudo-diphtheria to the true or Klebs-Löffler bacillus and its interchangeable virulent and transmittant attributes, are exemplified in the following case. The pseudo-diphtheria bacillus is considered a non-virulent, attenuated variety of the Klebs-Löffler bacillus, consequently should give rise to a mild form of the disease and propagate itself in its own form in the throats of other exposed children. It did neither in this instance, for babe S. died of heart failure after laryngeal stenosis due to the pseudo-bacillus that in its turn communicated a mild or aborted form of the disease to four other children who were not ill one minute, but nevertheless harbored the Löffler bacillus for some time. Such conflicting facts still demand explanation.

Case 2.—January 19. Babe S., 10 months old; slightly ailing; hoarse, coughing, coryza, faucial hyperemia, no patches. Morning temperature 101.6; evening temperature 99.2. Believing this to be a case of gripe, I gave it no further thought,

nor did I make a culture. January 21, the child reported better. January 22, the nurse telephoned to me that the babe had been croupy during the night. When I arrived at 2 p.m. the child was so dyspneic and cyanotic that Dr. Morganthau intubated for me; 1,600 units of antitoxin No. 2 was also given. Calomel sublimations and free stimulation was ordered. After recovering from the exhaustion incident to placing the tube, the babe's pulse and respiration were good. From the membrane and mucus coughed up a culture was made that demonstrated the pseudo-diphtheria bacillus. 5 p.m., child breathing comfortably, looked well, slept a couple of hours. 7 p.m., labored respiration, took milk and brandy well that was afterward regularly administered. 9 p.m., coughed up the tube, respiration labored; calomel sublimation: pulse 120, respiration 60, temperature 101.6. 12 m., pulse 120, respiration 60, temperature 101.6. 1 a.m., sleeping quietly. 1:30 a.m., the nurse noticed that the breathing was shallow and the child almost pulseless; no struggle, dyspnea or cyanosis. 1:20 a.m., it died; no autopsy permitted; death due probably to cardiac paralysis.

Case 3.—Babe E., 1 year old; seen December 29, eighteen hours after being taken sick. Patch on one tonsil; larynx involved to the point of beginning stenosis: temperature 103.4. Injected 10 c.c. of No. 3. January 1, great improvement: temperature 99; breathing comfortably. January 3, tonsil clean; child well. Almost a pure culture of the Löffler bacillus was demonstrated in this case, that infected the cousin Ellen E. with the pseudo-diphtheria bacillus, but who, because of antitoxin immunization, manifested no clinical signs of diphtheria. The antitoxin, however, produced in her eight days after injection pain, swelling and redness of one thigh and leg: 300 units from the same bottle, given to her brother, caused a generalized urticaria to appear in him.

Case 4 is another instance of the communication of the Klebs-Löffler bacillus infection, hence, true diphtheria, by means of the pseudo-diphtheria germ. Mary F., age 3½ years; seen January 2 upon the fourth day of her illness. Made a culture that showed a few pseudo-diphtheria bacilli and staphylococci. It was a severe pharyngeal and tonsillar type of the trouble and thirty-six hours after the injection of 10 c.c., of No. 2, the membrane was extruded *en masse*, the edges having first curled up. This same process was observed by me in several other cases. Cultures made again January 4 and 7, corroborated the original finding of pseudo-diphtheria bacillus. This child's mother had free intercourse with a neighboring cousin's family, where three days later I was asked to attend a case. I reached it January 5. Two children had been ill for twelve hours. The Löffler bacillus was found growing in their throats, and antitoxin given to them. Their recovery was rapid as compared to the supposedly lighter but really severer incursion of the pseudo-germ upon their cousin.

In a series of thirty cases I have cultural proof of bacterial infection minus clinical manifestation. In some of the cases there was absolutely no evidence of disease; in others such slight evidence that it was difficult to convince the parents of the reason for the exclusion of their children from the institution; in still others, because immunized by small doses of antitoxin, so mild an attack that it might be called aborted or modified diphtheria, for there was but slight rise of temperature, unimportant faucial hyperemia and no membrane visible. In these cases infection had probably taken place shortly before or at the time of injection, since they were not antitoxinized until we discovered by daily prophylactic cultures that a bacterial case at least had crept into "The Sheltering Home."

December 21. Isa G. sought admittance to the above institution. He was not sick but a culture disclosed the Löffler bacillus in his throat to the exclusion of all other germs. January 12, a clean bill of health permitted his entrance. He had received no antitoxin and seemed particularly insusceptible as did other members of his family.

January 21, Ida G. was reported sick; temperature 99.6; tonsils swollen; crypts patulous; Löffler bacillus present; no patches. Was isolated and given 500 units of antitoxin and twenty-one other children each given a 200 unit of immunizing dose completely protecting ten.

A like procedure, two months previous to this, had absolutely immunized twenty-four out of twenty-eight cases subjected to this treatment. Four of these cases

harbored the Löffler bacillus but were not sick. They were immunized for eight weeks, being more or less exposed during this period. Later we had another outbreak. Six adults refused immunization and one of them, just nine days after exposure, contracted the disease. The five remaining members of this household now allowed me to inject them. One, however, was not absolutely protected; for five days later a mild form of the trouble appeared in her. To return to the history of Ida G.; she never developed patches and seemed well although her temperature ranged from 99 to 99.6 and 100.6 for ten days and the bacillus was ever present and is still present sixteen days after the onset of her attack. She in turn infected the above-mentioned insusceptible case Isa G., and a sister who January 22 and 23 were respectively taken sick. Up to this date their throats were free but now showed the Löffler bacillus. The boy's temperature was 103 before administering the extra dose of 500 units of antitoxin but fell in twenty-four hours to 102.2. Throats of both were in the same condition as the previously described case. They were now sent home and escaped my farther observation. Daily cultures were now being made and the institution kept open. The urine examined in all these cases before and after receiving antitoxin, proved negative. Seven other inmates (none of whom became ill) developed a Löffler bacterial growth upon January 25, 29, 30, 31, February 3 and 4, respectively, viz., 3, 7, 8, 9, 12 and 13 days after exposure. These, the unrecognized contagion bearers, are during an epidemic, the most difficult subjects to deal with, and at any time a menace to others. In the cases that contracted the disease after antitoxin administration I was able to trace the infection as contemporaneous with the original source. The disease as thus contracted was also incipient or bacillary only.

Rashes appeared in 12 out of 269 subjects injected with antitoxin or a little over 5 per cent; a proportionately slight evil as compared to the benefit derived. Arthritis obtained in two cases; in one after a dose of No. 3, and in the other after a small immunizing dose. In the first case although croup, the cultural finding was negative. Both knees were here involved, while in case No. 2 it was the shoulder and wrist of the side injected. Edema, redness and an erythematous rash of one leg appeared in a little girl eight days after the reception of an immunizing dose. Her culture showed the pseudo-bacillus, although she was exposed to a Löffler bacillus infection. Her brother, who received some of the contents from the same bottle, developed urticaria. I saw another case of urticaria in a child who was subject to this malady. In still another instance, after an immunizing dose, a child who had previous attacks of eczema, now exhibited an additional outbreak. A papular rash appeared in five patients; in two, eight days, and in one, six days after the injection. A fourth subject was first seized by a papular affection followed by an urticarial eruption and left facial edema involving the left eyelid. No urine could be obtained for examination; nor was an analysis made in any of these cases. In an adult, eight days after injection an erysipelas-like rash appeared at the injection site in the anterior upper thoracic region and extended upward and outward to the point of the shoulder, inward to the middle sternal line and downward to the nipple. There was great pain and stiffness in all the joints of the upper extremity of that side, general pain, malaise and some rise

of temperature. Ichthyol ointment was applied by the attending physician who reported rapid improvement.

I have noticed that most patients have complained of pain and soreness after the injection and many children manifested much uneasiness the night after the administration of antitoxin. A few older patients returning to me some time after such a procedure complained that they had not felt well since. I saw a number of cases of unquestionable laryngeal diphtheria of great severity in which repeated cultures failed to demonstrate the Löffler bacillus. In some instances, this was due to the fact that the cases were seen at a late day when the field was overwhelmed with staphylococci and streptococci, and in others to the use of various antiseptic solutions and sprays. But again in many other cases where the last mentioned conditions obtained, I was able to secure cultures. Wherefore in some cases and not in all is a query requiring an answer.

CLINICAL NOTE UPON AN OVERDOSE OF PROTO-NUCLEIN.

BY H. V. WÜRDEMAN, M.D.

MILWAUKEE, WIS.

A female child, aged 3 years, parents of upper class; subject of malnutrition, from whom large amount of pharyngeal adenoids had been removed six weeks before; in addition to diet and general regimen had been given proto-nuclein tablets, 5 grs. each, taken twice to three times a day (Reed & Carnrick's). Had taken these for about a month. Great benefit as regards general health, the condition of the nose, throat and ears had followed. The improvement was mainly ascribed to removal of the adenoid tissue and restoration of nasal breathing. This child was addicted to eating lead pencils, pieces of chalk, etc., and had previously taken medicine of some kind in large quantity without knowledge of the parents.

On February 4 she was observed to be playing with a bottle which had contained proto-nuclein tablets, of which it is supposed twenty-five or thirty remained (125 to 150 grains or 8 to 10 grams). The bottle was found to be empty and a couple of the crushed tablets were removed from the mouth. She said she had eaten all that was there and parents are convinced of the fact. The child was brought to my office within an hour, when I could observe no apparent change from her general health. Advised half-hourly drinks of water with small lump of carbonate of magnesia. The spoiled child would not take the magnesia and drank the water only when she was inclined. Was seen at noon, when she appeared excitable, pulse full and fast (125). At 6 P.M. had been quite vivacious during afternoon; seemed otherwise well. Pulse 120, tongue clean, no pain. Had passed urine several times in her clothes (a general habit). Specimen could not be obtained. During the night she slept well and was seen the next morning, when nothing was observed. Since then child has been apparently well.

The ingestion of 8 to 10 grams (125 to 150 grains), from twenty-five to thirty times the usual dose of a presumably standard and fresh preparation, had no effect whatever beyond slight mental excitation and acceleration of the heart's action. We would not ascribe this to the environment, as neither the parents

nor myself had anxiety over the dose, as I have looked upon the preparation in the light of a condensed nutriment rather than as a drug. It is yet on trial with me, but in all cases in which I have used it no results have been observed which could be ascribed to the exhibition of the proto-nuclein itself. It has apparently no toxic effect, and is perhaps inert as regards any physiologic action.

805 Grand Avenue.

SOCIETY PROCEEDINGS.

Sanitary Conference of Pennsylvania.

Third Annual Meeting of the Associated Health Authorities of Pennsylvania, Jan. 23, 1896, at Harrisburg, Pa.

In the absence of the Governor, Mr. CROSBY GRAY, First Vice President, called the meeting to order. Prayer was offered by Rev. B. B. Hamlin, D.D. On behalf of the Mayor of Harrisburg, Dr. H. HAMILTON addressed the members in welcome to the city. Mr. Gray responded for the Association. A letter from Dr. L. Pierson, State Veterinarian, regretting his inability to be present, and on motion he was made an honorary member.

Dr. R. L. PITFIELD, Assistant Bacteriologist to the State Board of Health, read a paper entitled

THE BACTERIOLOGICAL ETIOLOGY AND DIAGNOSIS IN DIPHTHERIA.

He alluded to the interesting and valuable improvements in medicine in the last fifteen years. Among these is the scientific study of diphtheria, particularly since 1883, when Klebs first described its bacillus: a year later Löffler confirmed this, isolated it and with it produced the disease in lower animals. Not only the etiology has been made known, but its absolute diagnosis has been developed and a specific cure has been obtained. Roux, Behring and others have shown the antitoxic serum as its specific. Medical men can with pride view this progress; chemistry to-day is on the verge of a revolution, while medicine is more firmly enthroned. The bacillus of diphtheria is a slender, little rod, varying in size, shape and internal structure. By its variability we are able almost at once to recognize it. It is often club-shaped, with rounded ends, a slender middle, or it is spindle-shaped with pointed ends. The shape and general morphology vary as the age and conditions of growth, such as the chemie reaction of its food. On a solid medium it grows little grayish colonies, which are rounded with irregular edges, and are like ground glass in that they do not reflect the light. If stained with an aniline dye, various parts take up the color with varying intensity; some stain deeply, others but little; this gives a characteristic appearance to the bacillus. Often if a blue dye is used, black points appear in its continuity which do not transmit light. The bacillus can not move independently nor form spores. It grows best at the temperature of the body, and exposure to heat above 58 C. kills it in a short time. It has never been found "wild," that is, it is a distinct parasite and differs from some other pathogenic bacteria in this way. Cholera, for instance, exists normally in certain waters all the year round as a native. The native home of the bacillus is in the human mucous membrane of the throat especially, from which it may escape by coughing, by saliva, by contact with spoons, forks, cups, handkerchiefs or by kissing. It is also found in the air-passages of chickens, kittens and other animals. It is rarely found in the air and thrives best in moist places, if warm and dark. It readily grows upon a culture medium devised by Löffler, and for diagnosis this is best. This is called the Löffler blood-serum mixture. It is prepared by collecting the blood from an ox in a clean, sterile jar which has been slightly warmed, and after the clot is formed the fluid or serum is drawn off in sterile pipettes. This serum is then mixed with bouillon, one part bouillon to three of serum. The former containing 1 per cent. of glycerin. A little of the mixture is run into sterile test tubes plugged with cotton wool. They are placed in a hot chamber at a temperature of 78 C. in such a way as to slope the surface of the serum and make a large surface oblique to the sides of the tube. These are kept in the apparatus an hour or more till the serum is coagulated into a firm, translucent jelly, then they are sterilized for three consecutive days in a steam sterilizer twenty minutes each day in order to kill all stray bacteria which may have gotten in. To make a diagnosis of diphtheria, a sterile swab which has been kept in a sterile test tube is firmly rubbed over the membrane in the throat and this is gently rubbed over the moist surface of the serum

and then the tube is carefully replugged and put in an incubator and kept at the temperature of the body, 37 C. for twelve or more hours. If the case be diphtheria, on the surface of the serum will have crept a fine, delicate frosting of raised beads, close together, of a grayish color, semi-translucent; these are heaps of diphtheria bacilli, grown on the serum. With a delicate, flattened platinum wire, well flamed, a few of these are lifted off and gently rubbed on the surface of a clean cover slip, on which a drop of water has been placed. This is dried, stained with an alkaline solution of methyl blue, mounted, and when the lens is brought to bear on it, the field will be found full of delicate, little rods lying in all directions, often in clumps of a dozen or singly. By careful study the organism is seen to vary in size and general appearance, as before mentioned. This and the fact that it takes the stain in varying intensities enables one to make the diagnosis, especially if the culture appears normal to the naked eye. The diagnosis is best done if the swab is rubbed over the membrane before antiseptics have been used. We may find many other organisms, as yeast, molds and other bacteria, especially the staphylococcus, etc., which often cause abscesses. One strongly imitates the diphtheria bacillus in producing a membrane, and in its culture a frosting only a little whiter, but under the microscope it is seen to consist of a chain of little rounded bodies called cocci, which are in some way held together, and there is often a string of eight to sixteen. This organism is also the cause of many inflammatory diseases as erysipelas, puerperal fever, septicemia, and perhaps scarlet fever. Many apparently simple sore throats both with or without a membrane are caused by it. As the diphtheria bacillus developed in the throat, it produced a poisonous alkaloid called toxin, which penetrates the cells of the mucous membrane and the protoplasm of these coagulates, causing them to swell up and turn white as they die. This is the origin of the yellowish white membrane from which the disease takes its name. It is full of dead organisms. Often it mechanically interferes with breathing, especially if it grows on the larynx, and frequently in young children and even adults it causes death by suffocation. The poison penetrates the mucous membrane, the tonsils, lymphatic glands and the whole system, causing fever, depression, rapid pulse, and often paralysis of important nerves, not only of the limbs, but of the circulatory apparatus and the diaphragm: the heart is often overwhelmed and death results from acute poisoning. If the toxin is collected from old cultures by filtering off the germs, it will produce the same effects if given in large doses by injection to small animals; four drops will kill a guinea-pig in twenty-four to forty-eight hours; yet no germs were injected. The worst cases are where there is a mixture of diphtheria bacilli and the streptococci. Both toxins are absorbed and death ensues from a double poisoning. Serum tubes often show this mixture. Thus we are enabled to say if a case is diphtheria alone, or a mixed infection. Many epidemics of sore throat are caused by this streptococcus, and often have a membrane like diphtheria. The diagnosis is of great importance in those cases where the precious remedy, antitoxin, can be employed, for sore throats which are simply follicular tonsillitis need no antitoxin. Dr. Bissell, of Buffalo, says: "It is generally admitted that it is often impossible to make an accurate diagnosis either from a clinical or anatomic lesion or from both. There are no constant differences that separate the simple non-contagious forms of inflammation from the diphtheritic type and it is but a very small proportion of cases that an early and reliable diagnosis can be reached by any data obtainable. In Willard Parker Hospital 30 to 50 per cent. were found to be non-diphtheritic. Such a case with lowered vitality, if sent to a diphtheritic ward would almost surely be attacked by the more dangerous disease. In suspected cases it was found that 72 per cent. were real diphtheria. Children often are attacked by membranous croup, which is a mild diphtheria, killing more by suffocation than poisoning. I believe that in older people with more vitality the same organism is often present but causes only a temporary headache and fever. In epidemics the character of the disease varies much, from a low grade of virulence, perhaps a croup, to the most fatal form; yet the more fatal form may result from exposure to the milder. High vitality enables many to throw off the attack and no membrane forms; yet safety demands isolation of all such. It has been seen in thirteen families with no isolation, forty-eight children exposed to one with a mild form, 50 per cent had diphtheria subsequently. But where strict isolation was practiced, only 10 per cent. had the bacilli. All should be under suspicion till cultures showed the absence of the contagion. The bacillus does not often survive out of the human body and is easily killed by sunlight, heat and chemicals. It is spread more by direct contact than by the air, and has been found in emanations from

dead animals and in sewer gas. A small epidemic in my practice was traced to a game of marbles, all were sick, two died, and the father of one told me that all breathed on the marbles or held them in their mouths. Doubtless one had it and communicated it to the others. Slates often cause the disease. Think of the things that are put in the mouths by children: they often trade chewing gum, partly sucked candy, bitten apples. Apparently well people walk the streets with the bacilli in their throats; they complain but have no objective signs as membrane or enlarged tonsils. Park, in 330 examinations, found the bacilli in twenty-four, the virulent form in eight; hence the demand for care in all contact where there is the slightest doubt, when it can be so easily transmitted by kissing, handling an envelope sealed by the lips of such a one. Next we come to the important phase from a hygienic standpoint. It has been found after the disappearance of the membrane that the bacilli are still present in the throat and capable weeks after of producing the disease. One observer in 752 cases found an absolute disappearance of bacilli at the end of three days in 325; in 427 they persisted much longer: in 201 five to seven days; in 84, for twelve days; in 69, fifteen days; in 57, three weeks; in 11, four weeks; in 5, five weeks; in 1, for seven months after the disappearance of the membrane. Cultures made produced the disease in guinea-pigs within forty hours. This shows that the bacilli are able to cause infection long after the original case appears well and the need of thorough disinfection. It has been shown that in those cases where Löffler's solution has been used, recovery is soonest and the bacilli disappear earlier than in any other form of treatment. The deductions are that diagnosis requires bacteriologic aid. I am convinced that error is made where physicians say their results without antitoxin are equal or better than those with it; these are merely follicular tonsillitis. In conclusion, all suspects should be tested by the culture; all others in a family should also be examined; all should be strictly quarantined till the culture proves it not diphtheria; membrane croup should be considered diphtheria and so regulated.

In the absence of DR. R. MEADE BOLTON, Bacteriologist to the Philadelphia City Board of Health, the Secretary read his paper entitled "The Advantages of Bacteriologic Investigations to Boards of Health." He particularly alluded to the need of laboratories. Their usefulness depends upon the manner in which they are looked upon by the boards. The forlorn state of many scientific men in public laboratories is due to their being forced into a rut. If the board reposes confidence it must select the best men. All are not able to do this work. All need training before selection for the work. To know what to expect he described the working in his own laboratory. 1, The examination of pathologic material sent in by physicians; 2, preparation of diphtheria antitoxin; 3, experimental work upon questions pertaining to bacteriology. The first has consisted for the most part in the examination of cultures made from the throats of diphtheria suspects. Other work is the examination of sputum for tubercle, urine, cultures from wounds and tumors.

The system of examination was modeled upon that in New York City. After organization a circular was issued to physicians explaining what the laboratory was ready to do, telling how to make inoculations, tubes and swabs being sent for the purpose. Physicians have largely availed themselves of the opportunity. A culture outfit was shown; a tube with a cotton swab on an aluminium wire, and a little book for notes of the case. All are kept for reference. Results are sent by cards to the physicians. You should expect prompt recognition of diphtheria, consumption, etc. The preparation of diphtheria antitoxin is a part of the work, and other antitoxins must soon follow. The treating of infectious disease is as follows: Bacteria are now well known to cause disease. These are taken in with the food, drink, or by wounds, or the breath. They grow and reproduce and thus produce toxins. If the animal recovers, the toxins are neutralized in the body of the animal by the production of an antitoxin. Thus if diphtheria bacilli or their products are injected into an animal an antitoxin is produced in the animal. This cures the animal, but if drawn off can be used to cure others. The antitoxin is found in the fluids, notably in the liquor of the blood, also in the milk and elsewhere. The preparation of the antitoxin is done by gradually injecting a large quantity of the diphtheria toxin into a large animal, then drawing the blood of the animal. Horses are preferred. In the laboratories the production of all forms of antitoxins should now be a large part of the work. Select trained men, have well equipped laboratories, do not overburden them, expect prompt recognition of infectious diseases, the preparation of antitoxins and finally advances in knowledge of infections.

The matter of these papers was well discussed, and much

valuable information obtained by the eager sanitarians anxious to prove of value to their respective localities.

DR. A. H. HALBERSTADT, President of the Pottsville Board, who believed there existed a close relation between slaughter houses, bone boiling establishments and other noxious trades which fill the air with foul odors, offered a resolution to appoint a committee to examine this question from a bacteriologic standpoint and report next year. This was adopted, and an able committee appointed.

DR. JOSEPH MCFARLAND, Lecturer on Bacteriology, University of Pennsylvania, read a paper on "Diphtheria Antitoxic Serum." All are familiar with the fact that vegetable and animal cells produce powerful poisons. Now man and animals can accustom themselves to these poisons and endure a very large quantity, as in tobacco, opium, etc. So the hog, because of the slow absorption of rattlesnake poison through its layers of fat, gradually became accustomed to this poison. So with snake charmers, tolerance of the poison is secured. This was inexplicable till Emil Behring in Berlin discovered that, in the blood, there occurred a new substance capable of protecting the animal as well as other animals when injected into them. This must be known as new, having nothing to do with the normal blood. Its effect is to stimulate the cells so they can endure the poisons named. They are not chemically neutralizing agents. Diphtheria antitoxin is one of a group of remedial agents. So with rattlesnake and cobra poison, a specific is generated able to protect other animals into which they are introduced. Ehrlich has shown that when animals are immunized to large doses of ricin and abrin antitoxins, antiricin and anti-abrin are produced which will protect non-immunized animals. The toxin of diphtheria is the poison of the diphtheria bacilli. Diphtheria is not due to the throat lesion, but to the circulation in the blood of this poison. Hence in treating diphtheria the general poisoning is to be regarded. Each poison must be combated by its own antidote, or antitoxin. In diphtheria after recovery by use of antitoxin, the throat still contains virulent diphtheria, but as the symptoms are due to the circulation in the blood of the poison, we understand the recovery when we remember that the poison is no longer poisonous after the administration of antitoxin. Next it is important to make sure of good antitoxin. The mortality statistics show a diminution from 40 to 50 per cent. before the use of antitoxin to but 10 or 15 per cent. since. First, it must be strong. It is not a fatal dose to be arrived at, but the determination of the smallest fatal dose, which requires great nicety of calculation, time and the sacrifice of a large number of animals. Next is the personal equation of the experimenter and individual susceptibility of the guinea-pig. Normal antitoxin will with one-tenth of a c.c. protect a guinea-pig against ten times the smallest fatal dose of toxin. The serums ordinarily used are one hundred times as strong. Inexperienced persons can not test the serum. Fortunately, the exact strength of the antitoxin is of no importance therapeutically, because the exact dose required can never be estimated. There are, no doubt, cases in which we give ten times as much antitoxin as is really needed; at other times no doubt we give one-tenth as much as needed. It does not easily spoil. Many of you are aware that freshly drawn blood is germicidal and retains this power a long time. It is not safe to depend on this; it is best to add some substance which shall not interfere with its virtue and yet preserve it. He showed serums preserved with camphor, chloroform, salicylate of sodium, carbolic acid and tricresol. He preferred the two latter as more certain. These cause a flocculent precipitate which does not interfere but must be filtered off. Tricresol is three times as germicidal as carbolic acid and less than one third as poisonous. Objections exist to the use of antitoxin. Sudden death has been reported, but now no one regards this as true. Paralysis is apt to follow, but this occurs from diphtheria alone. Destructive action on the kidneys, this too occurs where it is not used. Or cases made diphtheria by its use, but antitoxin can not produce diphtheria. There are no germs in it. It would be quite as possible to develop a castor plant from a dose of castor oil. In its preparation, the cultures of diphtheria bacillus are first killed by the addition of a germicide, then filtered through unglazed porcelain. This sterile substance is injected in increasing quantities into the subcutaneous tissues of a horse until experiment shows the blood to contain antitoxin. The horse is then bled from a vein, the clear serum after coagulation pipetted off and preserved with tricresol. This is the antitoxin. The horse has never had diphtheria. The last objection is that it does not always succeed. We can not accept the statistics of those who have used it in a dozen cases, against those of a hundred, nor can we rely upon its use in combination with other remedies. On the lower animals its action is invariable. In the early stages in proper dosage, large enough, there is almost no fatality. Every case

can not be cured, first because we do not know how much toxin is in the blood and hence do not use enough antitoxin; second, because the toxin produces rapid disorganization of the nervous centers, which can never be regenerated. A few cases dying is no reason for rejecting a remedy which has in all parts of the world shown an extraordinary efficiency, so that some assert that it is God's latest and best gift to his children.

Recess was taken till 2:30 p.m.

On reassembling, DR. PITFIELD offered the following:

Resolved, That this Association recommend the antitoxin of diphtheria as preventive of diphtheria.

This provoked much discussion as not being proper from an Association composed of a very large number not learned in medicine, etc. On motion it was laid on the table.

DR. PITFIELD then moved the appointment of a committee to investigate and report next year. After still further discussion on motion of Dr. W. B. Atkinson, the subject was referred to the State Medical Society of Pennsylvania, asking them to inform this Association of their investigation.

Reports of various committees were received and filed.

The special committee on teaching physiology in the public schools reported, showing the many and egregious errors in the books selected for text books, many of which caused laughter in the meeting; the committee had found the authors and publishers willing to correct these errors, etc. On motion the committee was continued till they saw these changes made.

DR. J. T. ROTHROCK, State Forestry Commissioner, addressed the Association on the relation of forests to the water supply. Major Raymond says that all the water that falls on a forest is taken up by the ground, but all that falls on cleared ground soaks in and runs away. In several valleys cleared by the ax and fire he had observed the results of inundations. These valleys were very dry. These inundations destroy life and property. When the leaves and brush intercept the rainfall, it is carried beyond the chance of immediate evaporation, or running away. Growing trees give off water equal to thousands of billions of tons, in a season. The moisture in the atmosphere is a means by which excess of heat is prevented, and loss of heat which is needed to prevent freezing of vegetables, etc. An even temperature is thus preserved. New York has 3,700,000 acres in the Adirondacks, it needs only two forest reservations, while Pennsylvania requires more, as we can not obtain such large parks; hence, we would start with eight miles-square parks which will be object lessons to all. We ought to own all the mountain tops, as the owners are compelled to pay taxes for unproductive land, and must clear away the wood to pay it. Some have paid more tax than the ground would sell for. We should preserve our water, and not be compelled to filter it. There are 1,000 square miles lying between Luzerne, Lackawanna, Monroe and Pike Counties, practically worthless, but a magnificent water shed; as these can be had cheap, we ought to secure them. Forests have grown up within the recollection of the speaker. If fire is kept away they reproduce themselves. Coal is not inexhaustible; we must have some other supply for heat and light; therefore, to generate electricity for heat and light we must have water supplies and must keep our forests.

DR. LEE inquired if he would again bring up the Act which he read and which had been before the legislature at the last session?

DR. ROTHROCK—Yes! Till doomsday unless we get it before. The only reason for its non-passage at the last session was a lack of funds in the State Treasury.

On motion of Dr. Lee it was resolved that the Associated Health Authorities of Pennsylvania heartily endorse the efforts of the State Department of Agriculture, and of the State Forestry Commissioner to obtain the passage of an Act to establish Forestry Reservations at different points in this State as a means of maintaining the purity and permanence of water supplies.

A delegate from Scranton asked that the Associated Health Authorities of Lackawanna County be recognized by this Association.

On motion of Dr. R. Maison a Committee was appointed to consider and report on the relations of such bodies to this Association.

DR. GROFF of the Committee on Legislation reported their success in preventing the passage of the Act to destroy the local Boards of Health.

In the evening, PROF. F. C. PHILLIPS, of the Western University of Pennsylvania, Chemist to the State Board of Health, read a paper on the "Protection of Water Supplies." He believed in the protection of the rivers. He mentioned the Allegheny and Monongahela surrounded with beautiful hills, but a near inspection shows a frightful condition; refuse and

garbage spread around from the towns and people along the banks. The smell is intolerable. Here the markets and slaughterhouses empty their refuse, which decays in the rays of the sun; further up are the culm and slack from the coal mines, the washings of the coke furnaces, etc. The pyrites washed into the river is carried into the boilers, injuring them; the acids from the galvanizing works, from the stock yards the nitrogenous compounds, the offal, all help to make up a disgusting, dangerous mass to go into the water as the rain raises its level and flows down to the reservoirs below. The deforesting of the land in the west and northwest where these rivers rise causes the washing of the soil into the stream, and with the matters just mentioned increases largely the pollution, at present three times what it was twenty years ago. In the Monongahela the original amount of carbonate of lime was small, now this is neutralized with the free acids and the iron works can not use the water without the employment of a neutralizer or it destroys the boilers in a few weeks. That water purifies itself is believed by many. This is a doubtful matter. It is surprising to find how organic matter accumulates at the bottom of a river. Typhoid germs live 100 days in ordinary water; while they do not increase, they are active. We have no law to prevent stream pollution. Pittsburg can employ an old law within five miles of its borders, but there is no penalty attached. Allegheny does much to prevent pollution by an old law. The State Board has done much, but we must bring people to understand the necessity of caring for the water by abating these nuisances. In starting new works, the idea is to use the nearest water and pour all into it. Eleven States are protecting their streams. Others appear to think it better to purify the water after it is polluted. The remedy is to have Congress appoint a Rivers Conservancy Board. This would be excellent for Pennsylvania. Till then, the State Health Board should have control over this matter, and act at its discretion. It is difficult to suggest the best plan as legislation is opposed by those with a pecuniary interest. We must influence the people. We must educate them to the vast importance of this matter. A very important need is to require all hospitals to purify their sewerage. This would be an object lesson. Leaflets on the matter, lectures on water supplies, conventions of all kinds should take it up. But unfortunately these meet in large cities where the water is known to be pure. Yet many delegates incur a great risk by drinking the water in which are typhoid germs. Water meters should be used to stay the waste of water. Too much waste makes more sewage to purify.

DR. ROTHROCK believed we could obtain the aid of the people if they were fully informed of the dangers from this source. The way is, at all teachers' conventions and institutes, to bring before them the need of legislation to prevent this source of disease and death being continued. Employ every way to instruct the people, rouse public sentiment and they will no longer tolerate it.

DR. LEE said it was worse below Pittsburg than above. Braddock's slaughter houses dump all into the water; this runs sluggishly and the stuff lies in a festering mass, filled with maggots, etc.

It was finally agreed that the Committee on Legislation should prepare an Act on this matter and present it to the legislature without reference to the Association.

Adjourned till morning.

On Friday morning, DR. LEE read and commented on the new law relative to the report, etc., of contagious diseases.

It was resolved that the Legislative Committee be instructed to prepare and present to the legislature a Bill to increase the powers of the State Board of Health, as well as the annual appropriation, and to confer with the local boards urging each to use its influence with the members of the legislature to promote its enactment.

A letter from H. H. Quimby, President of the School Directors' Association of the State, relative to the great need of township boards of health, urging that the school boards be impressed with the importance of sanitary measures. The most fruitful field for the propagation of disease is the public school, hence school directors who have the power to close the schools during the prevalence of epidemics should be brought to understand their duties in this respect.

DR. LEE explained what had been done in this respect.

On motion the letter was referred to the State Board with the request that appropriate circulars be sent to the school boards of the rural districts.

The Secretary read a paper by Dr. Edward O. Shakespeare "The Production, Transport, Sale and Delivery of Dairy Products should be under the Sanitary Control of the Labor Board of Health where these Products are Consumed." The liability of these products to become infected with disease

before they reach the consumer, the epidemic thus caused, cholera infantum, tuberculosis in infancy, were alluded to. Intervention should begin at the beginning, and continue till the consumer is reached. It should be executed first and best through the accredited and responsible agents of the local board of health of the consumer. The dairy farm is the one chief source where milk becomes infected. The dealer's shop, for reception of the milk supply and its distribution to the consumer, is the other chief source of contamination. Prevention of infection at both will curtail much of the mortality from infected milk. The first is rarely if ever reached. A sanitary inspection of the cows, their food, surroundings, water supply, health of the dairymen, the collecting and handling of the milk made at unexpected times repeatedly, to exclude diseased cattle, infection of the milk, is essential; then a rigid inspection of the shop, etc. The agents must be thoroughly reliable, and well informed. He must not be influenced by commercial interest or mercenary motives. Otherwise the inspection will be worthless. A proper license system is absolutely needed. This to be wholly in the hands of the health authority. Cost to be nominal to the producer, more expensive to the dealer. The invested capital of the former is much greater. Milk from unlicensed to be prohibited entering the health districts. While it may be objected that this is an unwarrantable interference with individual rights, it must be remembered that the milk business is one of the most dangerous of human occupations. People have a right to this protection.

This paper was discussed and approved by the members.

On motion of Mr. Gallagher the Legislative Committee was directed to prepare a bill to present to the next legislature, covering the ground stated. An amendment to the plan of organization of the Association was adopted admitting all health boards which had united in a county health association at the rate of \$2.50 each.

The annual election was then held, resulting: First Vice-President, Crosby Gray, Pittsburg; Second Vice-President, Dr. J. S. Hunt, Easton; Third Vice-President, A. M. Sloan, Esq., Greensburg; Secretary, Dr. Wm. B. Atkinson, Philadelphia; Treasurer, Dr. Jesse C. Green, West Chester. The usual standing committees were appointed, and the Association closed its session after some remarks by Mr. Crosby Gray.

Chicago Ophthalmological and Otological Society.

Annual Meeting held at the Chicago Athletic Association Hall Jan. 14 1896.

Dr. F. C. Hotz in the chair.

There were twenty-two members and visitors in attendance. Minutes of the last meeting were read and approved.

Dr. GRADLE showed a patient whose case had been reported to the Society in April, 1895. At that time he was suffering from paralysis of some of the extrinsic muscles, but the condition was improving under moderate doses of iodid of potash. There had never been any syphilitic history, or any reason to believe that syphilis was a factor in the case. Iodid was continued all through the summer in larger doses, and toward the fall all the symptoms had disappeared with the exception of increased knee jerk and an unnatural gait. At present the only symptom is that in extreme excursion of the eyes in any direction there is nystagmus and a rapid shaking of the head in the plane of the excursion, also a slight lagophthalmus in the left eye with a twitching of the orbicularis. The iodid had been stopped last fall and injections were tried, but after a few applications a violent stomatitis started up and the mercury was stopped. About a week after this stomatitis had subsided, the field to the right was hazy, although the perimeter showed no contraction. A few days later the patient complained of poor vision in both eyes. Although the test card showed normal vision, still the reading of letters was very slow and difficult instead of rapid and easy as heretofore. The accommodation also was somewhat diminished. In November the iodid was started again in large doses, and these symptoms disappeared. Shortly before Christmas vision in the left eye was nearly lost; color vision entirely gone. There were at no time any ophthalmoscopic appearances. Since Christmas the vision in the left eye has improved. Dr. Gradle thinks that the recent attack is probably one of retrobulbar neuritis now improving.

Dr. WOOD examined the case and thought that the nystagmus resembled that which we see in practically normal eyes on extreme excursions to the side, or up or down.

Dr. TILLEY suggested that possibly the condition of the nose might explain the symptoms.

Dr. HOTZ was inclined to think that a central lesion was present.

Dr. GRADLE said that the original paralysis of the extrinsic muscles must undoubtedly have been nuclear, but that the recent affection of the left eye, as far as he knew, could only be some trouble with the nerve between the bulb and the chiasm.

The next business was the election of officers. Dr. H. Gradle was elected President: Dr. C. D. Wescott, Vice-President; Dr. Pinckard, Secretary, and Drs. Hotz, Coleman and H. H. Brown, the Committee on Membership.

On motion, a committee was appointed by the Chair (the Secretary being one of the committee) to consider the advisability of any changes or additions to the By-Laws of the Society, governing all questions of membership, dues and procedure.

DRS. TILLEY and HALE were appointed to act with the Secretary on this committee.

DRS. E. T. Dickerman, C. E. Robertson, S. L. McCreight, T. A. Woodruff, and H. V. Würdemann, were elected members.

The report of the Treasurer showed a balance of \$20.80.

On motion, the Secretary was instructed to cancel the assessment of Dr. H. Weir.

The application of Dr. H. J. Hornbogen, of Marquette, Mich., was read and referred to the Committee on Membership.

On motion, the Secretary was instructed to use the funds of the Society, if necessary, in order to complete the guarantee for the dinners.

Dr. Hotz then read

REPORT OF A CASE OF CILIARY NEUROSIS.

In November, 1887, Mr. L. S., aged 41, consulted him for recurrent attacks of pain in the right eye, the attacks coming on between 3 and 4 o'clock in the morning, usually lasting but a few minutes; sometimes, when severe, an hour. The pain resembled that from a foreign body under the eyelid, attended with great photophobia and profuse lachrymation, with an edema of the upper lid and injection of the conjunctiva. The vision was always blurred by an attack and continued so for a short time. The attacks had lasted for some nine years. Sometimes he was free from them for several months; at other times he had one every night for a week or more. During the free intervals vision was clear. Ten years ago his left eye had been enucleated by Dr. Reuling, who stated to Dr. Hotz that the left eye at that time had been lost from irido-choroiditis in childhood, and that there were some symptoms of sympathetic trouble in the right. The healing of the left eye after enucleation was rapid and normal. Vision at that time with a correcting cylinder was normal in the right eye. Dr. Hotz laid considerable stress on this report as showing beyond doubt that ciliary neuralgia was present in the right eye at that time. Mr. S., however, ascribes all his trouble to a scratch on the cornea inflicted by a child about a year after the enucleation. Dr. Hotz was not inclined to place so much importance on this circumstance; however, unquestionably slight corneal wounds have often caused very troublesome neuralgic pains, but they do not as a rule last as long as in this case. There has never been any increase of pressure; pupillary action normal, vitreous clear and fundus normal. No tenderness on pressure. At that examination he thought he could see by a focal light a very minute gray line in the cornea. These paroxysms of pain being rather regular in appearance, quinin suggested itself as a remedy, and for the first week after its use the eye was free from pain. It then returned, and quinin has never had any effect since. Cocain, however, gave temporary relief. In January, 1889, all constitutional treatment was discontinued and the eye put under the influence of atropin. For a week again the eye was free from pain, but it returned. During this week the refraction was retested and a glass $.75\text{C} + 1.50\text{ax. } 90^\circ$, vision normal. The doctor believed that this discovery was of great importance in causing ciliary trouble, but again his hopes were shattered, for in spite of the constant use of the correct lens the attacks returned. In February, 1889, Mr. S. went to New York and consulted Dr. Grüning, who found the eye free from all irritation, but the enucleation scar in the left eye somewhat irritated, and operated on that. The wound healed very kindly, but the patient reported in March that the pains had returned. After April, 1889, the patient was not seen again until January, 1892, when he stated that from May until October of 1890, he had been comparatively free from pain, but that lately they had become more frequent again, and whereas formerly the pain was confined to the eyeball, it now extended over the whole right side of the head. The attacks occurred at the same time, between 3 and 4 in the morning, with the other symptoms about the same. Between January and July of 1892, antipyrin, salicylate of sodium, iodid of potash and mercurials were tried, also the continued use of atropin for six weeks, but the

attacks continued just the same. In July the patient was examined by Dr. Beard, who thought that the retinal arteries were quite small and the veins easily pulsated, and suggested that the patient's heart, which was irritable, might play some part in the case, and that he cease smoking, which he did for six months without any relief.

In August Dr. Hotz received a message to visit the patient at his house. All the night before he had been suffering from incessant pain in the eye and right side of the head, and cocaine had been given with very little relief. Dr. Hotz found the upper lid very edematous, the eye very red, sensitive to touch, and the epithelium of the whole lower half of the cornea was hazy and separated from Bowman's membrane in a large bleb. Atropin was instilled, bandage applied, and in five days the eye completely recovered from this attack. Again, in October, a similar attack of keratitis bullosa occurred, involving again the lower half of the cornea. During the winter of 1893 the attacks of pain continued, and in the spring and summer of 1894 they were more frequent, but seldom severe. The vision has been repeatedly tested in from six to eight hours after an attack, and the same result always obtained. Unquestionably the dimness of vision occurring after the attacks was due to a spasmodic contraction of the ciliary muscle, because the vision was always normal with an additional weak concave lens or the use of atropin. The question of diagnosis lies between cyclitis, glaucoma, and pure ciliary neurosis. Glaucoma has never been shown in any way in the case. Cyclitis could hardly have existed for so long a period without leaving some permanent changes in the eye. Probably the case is a pure ciliary neurosis. In the literature the only cases similar to this reported are by Dr. Samelsohn in Graefe's Archives for 1875. In that article a number of cases are quoted and the cause ascribed to vasomotor changes.

Dr. GRADLE had seen this patient both before and after he had been under Dr. Hotz's treatment. He first saw him in 1880 and had him under observation until 1887. He agreed with Dr. Hotz's description of the symptoms, and had also tried the remedies that Dr. Hotz had used. In addition he had thought at one time that the trouble was aggravated by the condition of the nose and cauterized the turbinate and septum for catarrhal trouble, but without any effect on the neurosis. He next saw him in 1894, when he was still in practically the same condition as before he left him. In September of 1894 he returned again for treatment, the attacks being more frequent. Salicylic acid internally at that time seemed to lessen the severity of the attacks somewhat. At Dr. Gradle's suggestion the patient began to keep a record of the attacks, dividing them into four degrees of severity, and making weekly records of the number and violence of the attacks. Dr. Gradle thought that pilocarpin might be of benefit, and it was tried with considerable relief. Eserin had an unhappy effect on the patient, and that was tried and shortly discontinued. Dr. Gradle believes that the pain is due to irritation of a nerve fiber in this scar, or an irritation in the course of the nerve, although he had never been able to see the scar since a year after the injury.

Dr. HOLMES suggested that latent gout might be a cause, but Dr. Hotz said that colchicum had been tried without benefit.

Dr. TILLEY thought that empyema of the antrum would account for the symptoms, and spoke of a case where the symptoms were relieved by the antrum being drained.

Dr. COLBURN saw one case in which repeated attacks of keratitis bullosa were followed by blindness from opacity in the cornea, and the globe was enucleated for pain.

The Society adjourned by limitation.

C. P. PINCKARD, Secretary.

103 State Street.

SELECTIONS.

The Craig Colony of New York State.—The Craig Colony for Epileptics was opened January 20, by the preparation of quarters for thirty patients. These will be selected by Dr. Hoyt, of the State Board of Charities, being geographically distributed. Later, others will be received from county almshouses, until the full list of 200 is reached. Applications from all over the United States are received, even from other countries, Canada, South America, Russia and Asia. The object of this admirable undertaking is well stated in an editorial in the *American Practitioner*, for November 16, as follows: "The object of the colony is to provide for the four great needs of these unfortun-

nates: 1. To give them schools where they may be educated as other children and young people are. 2. To afford them industrial training in any sort of occupation they may desire to follow. 3. To provide those epileptics a home to whom all other doors are closed. 4. To treat every case of epilepsy according to the best known scientific methods." The writer also makes the following comments on the grand scope of the work: "The idea of forming colonies for persons suffering with chronic incurable diseases is not new, for the leprosy have been colonized since early times; but in this and similar instances the sick were segregated for the benefit of the well, and not out of any special regard for the former. The extension of the practice for the good of the afflicted is purely humanitarian and the natural outgrowth of the spirit of altruism which now pervades christendom. There can be no question that epileptics can be better managed and more successfully treated in institutions devoted to the purpose than at home or in the public hospitals and dispensaries; but private institutions can avail the poor nothing, and they are compelled to drag out a wretched existence, handicapped by a cruel disease, shunned by their neighbors, and neglected, through ignorance or necessity, by their kin. To such a State sanitarium or farm is indeed a godsend, nor is it to be forgotten that many who are able to pay for care and treatment would gladly escape into such a place from surroundings wherein their epileptic seizures are a perpetual source of mortification. The work is Christian, is humanitarian, is beneficent, and no argument is needed to commend it to the favor of every lover of his kind. It is stated that Massachusetts and Ohio are preparing to follow the lead of New York in this good work, and there can be little doubt that the other States will soon do likewise." Let it be remembered that while the colony will, no doubt, for all time bear the name of a worthy and charitable layman, the chief brunt of the laborious organizing work has been borne by a junior member of our profession, Dr. Frederick Peterson, of New York city. Dr. Peterson has been in practice about fifteen years, and during the latter half of that period has spared himself in no way in order to bring about the required legislation and appropriations and laying out of plans. It will be a perennial monument to his unselfish charity, although it will never bear his name. One of his first, if not the first, contributions on the subject of the colonization of epileptics, was a descriptive paper published in 1886, regarding the colony at Bielefeld in Westphalia, Rhenish Prussia, which began in 1867 with four patients. See also this JOURNAL, Vol. xxv, page 598.

Erythropsia.—Dr. Myles Standish, in the *Boston Medical and Surgical Journal*, reviews a contribution by Dr. L. Fuchs in *Annales d'Oculistique*, September. That writer "noticed on climbing a high snow-covered mountain that when he entered a hut erected on the top, everything appeared red. This suggested a series of experiments which seemed to show that in order to elicit the erythropsia in the normal eye, it is necessary to expose it for some length of time to the glare of the snow upon which the sun is shining, and that this was still more quickly accomplished if cataract cases were exposed to a reflection of light from the snow. As a result of his experiments, he states that the erythropsia of normal eyes, as well as of eyes deprived of their lenses, is caused by dazzling, which need not be disagreeably strong, but must be of long duration. Exposure to sunlight reflected by snow is the most effective means of producing it. For most eyes, however, it is necessary that the dazzling shall take place high above the level of the sea, where the sunlight is stronger and also richer in short-waved rays. He found by trial that the phenomenon was produced on patients who had been operated on for cataract, without regard to elevation above the sea-level. He draws attention to the fact that the color of the erythropsia is exactly like the color of the retinal purple, also that the erythropsia is, as a rule, less pro-

nounced or entirely absent in the part of the field of vision which corresponds to the macula lutea, and thinks that by long exposure to strong light the retinal purple is bleached and the retina becomes uncolored, and that phenomenon is seen during the re-establishment of the retinal purple."

Contribution to the Study of Gelseminin.—The tincture of gelsemium and the fluid extract of gelsemium, both obtained from the root of the *Gelsemium Sempervirens*, have been rather neglected lately, on account of our ignorance of its active principles and their mode of action. A recent article in the *Pharm. Ztg.* of Nov. 18, 1895, describes the chemic character of pure gelseminin, and some of its compounds. The oxidation of gelseminin ($C_{22}H_{26}N_2O_9$), with permanganate of potassium results in a salt: the formula for its composition being $C_{18}H_{19}N_2O_9$. The quantity produced was so small that no further experiments were made with it. Separating under the influence of the hydrate of potash the iodomethylate of gelseminin produces the chlorhydrate of a volatile base, with the formula $E_{13}H_{22}NO_4HCl$: a salt (the chlorhydrate of gelseminin) with the formula $C_{21}H_{11}NHCl$: another salt with the formula $C_{10}H_{11}NHCl$: and a resinous substance composed as follows: $C_{10}H_{13}N$. This last substance, dried and pulverized, is a fine, very bitter powder. There is every reason to believe that this is an entirely new substance, having nothing in common with any other compound hitherto known possessing the same formula for its composition.—*Les Nouv. Remèdes*, Jan. 8, 1896.

A Stout String as an Obstetric Aid.—A physician writes to the *Rev. de Ther.*, November, 1895, describing the assistance he derives from a stout string about a meter and a half long, in his obstetric practice. The patient placed in the usual position with the forceps in place, the physician seats himself on rather a low chair in front, as if to make an examination with the speculum. The string has a loop on one end which he fastens to the left handle of the forceps. It is then carried across to the right handle, making a figure 8, two or three times repeated. Then the string is passed from left to right behind the physician's back, brought around and fastened to the right handle. By bracing against the string around his loins, the physician can control the forceps while his hands are left free to guide it, moving it up or down, to right or left, simply by twisting his body a little on the chair. With ordinary care this use of a string is a great advantage, but in careless hands it might do damage. The string must be the diameter of a penholder to insure its not breaking.—*La Province Médicale*, January 4.

Splenopexis; Operation for Wandering Spleen. The treatment of wandering spleen by artificially fastening it to the parietal peritoneum is an operation of comparatively recent date. Since Rydygier showed that the extirpation of the spleen is not so entirely without significance for the organism, the attempt has been made to proceed with more conservatism. Konwer describes in the *Nederl. Tijdschr. v. Gen.* 1895, No. 15, a case treated by him, in which he made an opening as if to remove the kidney, and manipulating the spleen through the abdomen, he pressed it down opposite the opening, where it was held in place with cotton pads and tight bandages. An attempt to sew it failed, but the operation resulted successfully without this, and four years have passed since, without a relapse. The spleen was not restored to its former place, but Konwer thinks this is immaterial, as long as it does not interfere with any other organ. Similar treatment failed in another case, as the bandages had to be laid aside the sixth day to arrest occlusion of the intestines. *Centralblatt für Chir.* January 10.

Prejudice Against New Treatment for Hypertrophied Prostate. Dr. Englisch recently delivered an address on the subject of the treatment of hypertrophy of the prostate gland before the k. k. Ges. of Vienna Physicians, in which he reviewed the whole

subject and asserted that there was not a single case on record of complications following the operation of castration for this purpose. Wherever there was trouble it was traced directly to previous abnormal conditions. He dwelt at length upon the disinclination of patients to submit to castration, and remarked that the method of suppressing the functions of the testicles by tying the vas deferens seems to have a more promising future before it than the former method. In the discussion that followed Dr. Dittel asserted that it might be accepted that this tying operation would have the same effect as castration upon the relations existing between the testicles and the prostate gland.—*Wiener klin. Rundschau*, Jan. 5, 1896.

The Role of Chlorin in Narcotic Poisons, Especially in Acetone.—There is no relation between the narcotic power and the amount of chlorin in those compounds in which the hydrogen has been replaced by chlorin, bromin or iodine. We are obliged to admit that their hypnotic properties depend on the energy with which the halogen is retained, or the ease with which it is liberated. This explains the notable difference in narcotic power between the chlorid of ethylene and the chlorid of ethyl. After dwelling upon this fact, Kossa describes in the *Ung. Arch. f. Med.*, 1895, Nos. 3 and 4, the effect of a recent compound, acetone chloroform, or as the same writer calls it trichlorpseudobutyl-alcohol. Administered hypodermically to rabbits it produces sleep very soon. Given to persons through the mouth, in a dose from 0gr.8 to 1gr.3, it produces an agreeable slumber, with no noticeable disturbance of the heart or respiration.—*Les Nouv. Remèdes*, Jan. 8, 1896.

Experimental Researches on the Physiologic Effect of Anemonin.—Anemonin usually comes in the form of orthorhombic crystals, with an odor *sui generis*: it dissolves very little in water, alcohol or ether. Repeated experiments with it on rabbits, frogs, guinea-pigs and dogs, show that it is a slow poison, the first indications of which are drowsiness followed by paralysis, and terminating in convulsions. The torpor is evidently due to the physico-chemic action of the drug on the brain. The anemonin commences by affecting the brain and does not act upon the spinal cord until later. The intensity of the convulsions varies: sometimes they are merely isolated spasms. Death is produced by the cessation of respiration, the muscles losing completely their contractility.—*Brit. Med. Jour.*, Nov. 2, 1895. Reviewed in *Les Nouv. Remèdes*, Jan. 8, 1896.

Congenital Hydrocephalus with No Clinical Manifestations until Adult Manhood. The *Gazz. degli Osp. e. Clin.* of Jan. 4, 1896, contains a detailed study of a typical case of congenital hydrocephalus which did not reveal its presence until late in life. The patient was a clerk, an Italian, of fair average mental development and no bad habits, with no apparent physical defects except an affection of the left eye, which finally lost its sight. In his twenty-third year he was suddenly and violently attacked with vomiting, vertigo, cephalalgia and other symptoms which gradually grew worse, until there was the combination that is the unmistakable picture of congenital hydrocephalus. Death ensued at 34 years of age. At first it was very difficult to differentiate the case, but as time passed, all doubts vanished, and the autopsy confirmed the original diagnosis.

Elimination Through the Stomach. Experiments have been made recently on healthy dogs to determine what substances find their way into the stomach when introduced into the system by rectal or hypodermic injection. The alkaloids discovered in the vomit withdrawn mechanically from the stomach were morphin, brucin, veratrin, caffein and quinin. There was absence of atropin and apomorphin. Other substances found were salicylic acid and antipyrin. Phenic acid was not eliminated by the stomach. Still other substances noticed were chloroform, chloral hydrate, methyl alcohol, ethyl alcohol and acetone. The methyl alcohol was administered in a rectal injection. It was mostly eliminated in the urine the day after the injection. These substances found their way into the stomach through the blood in some cases, but Grützner's recent experiments show that there is an antiperistaltic action of the bowels to which may be due the presence in the stomach of some of the substances introduced into the rectum.—*Schmidt's Jahrbch.*, 1895, No. 11; reviewed in *Les Nouv. Remèdes*, Jan. 8, 1896.

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00

SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.

W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, FEBRUARY 22, 1896.

SANITARY LIMITATIONS.

The development of hygiene as a department of medicine is the prominent professional characteristic of this age. From a scarcely tolerated subsidiary to physiology or medical jurisprudence in a few schools, it has risen to become an important chair in all colleges of the highest standing. Health associations, health boards and health journals abound, and that which was itself only a subordinate study, has been the parent of another as abstruse and difficult as any of the older branches in medical science. Bacteriology alone is a special object of research, and works treating of it have the proportions and intricacies of old text-books. The public health is the refrain in the periodical professional literature; and the office of the practitioner to medicine would appear to be menaced as a sinecure.

Nevertheless, the insanitary doings of the people go on, and they continue to defy the unselfish counsels that aim to banish disease and death. Is this significant of the hopelessness of the task? Does it suggest that there are limitations to sanitary effort, which it is idle to hope to surmount?

A single illustration suffices. It ought to be manifest to the simplest intelligence that fresh air, free air, and sunlight are essentials to healthy development and vigor of body. Barbarous races demonstrate that fact by their lusty frames and their freedom from the morbidic pests of civilization, yet not alone the lower classes of our great cities, but their wealthy and educated inhabitants as well are equally indifferent to the truth that to breathe fresh air and live in the sunshine are more potent invigorators than apothecaries' stuffs at a dollar a bottle. The faces of the throngs in

the street cars of our great cities, hurrying to and from their daily occupations, bear the evidence of race degeneracy in their pallid or sallow complexions. The ruddiness of the Anglo-Saxon is disappearing, chiefly because these people pass the greater portion of their lives in rooms, in which direct sunlight rarely enters. The apartment-house system is attaining appalling dimensions, as in New York City, where even suites, which rent for a thousand dollars a year or more, have as their prominent feature dark interior bedrooms, opening upon wells, into which the rays of the sun can never penetrate. With attractive approaches and entrances from the street, elevators and decorated drawing-rooms, there coexist small chambers, with windows facing blank brick walls, near enough to be touched, six or seven stories high. The occupants of the lower apartments breathe only the stagnant air at the bottom of the narrow space (well) outside their windows, yet apartments of this sort are not only readily rented, but when rented are further obstructed and darkened by superfluous hangings. The ignorance or indifference of even wealthy lessees is shown by one instance of many in view, of a suite of rooms on the second floor of a most expensive establishment, occupied by a family in affluent circumstances. All the windows face north and are closed with heavy inner and outer curtains, thus even excluding the sun's rays reflected from the houses on the opposite side of the street, ever burning gas lights supplying the illumination necessary to prevent stumbling over the multitudinous articles of furniture, which encroach upon the air space, and only evidence the purchasing ability of the occupant. Even greater folly than this is that of the owner and resident of a large brownstone house on the northeast corner of a splendid avenue, the length of the house having an unobstructed southern exposure on a street running east and west. In this wide surface are spaces for twenty-one windows, *fourteen* of which are blind, having been filled in by brownstone slabs, leaving only the indicated sites of windows as designed by the architect. Sanitary teaching is idle addressed to such a person. The pallid, shivering, ill-developed children are only weighted more and more by furs and heavy wraps. Only a day or two ago, the writer entered a cable-car crowded to the point of stifling, and aroused the ire of the passengers by opening an overhead ventilator near him; and two ladies, expensively clad, conspicuously drew their capes around their shoulders and moved their seats at the first opportunity. What, then, can be expected from the hordes of the tenement houses, who find stupifying warmth in their sealed doors, when the rich and presumably intelligent themselves violate the warnings of the sanitarian? Owners and architects will continue building long rows of dark, ill-ventilated apartments, which the necessities and indifference of tenants

cause them to occupy, with the certain physical impairment of the children to be born and reared in their dim, murky interiors.

Perhaps a more glaring disregard of sanitary considerations is that exhibited in the street cars of all our cities, by the tolerance of the expectorator, who voids a mess as disgusting as a vomit on the floors of vehicles used by the public. It is amazing that no serious effort has been made to put a stop to the abominable, offensive practice. Men, well dressed, with intelligent faces and apparently aware of the proprieties of life, do not hesitate to discharge upon the floor the viscid accumulations of saliva, mucus and pus in full view of their fellow passengers to besmear the skirts of the young girl or woman who next occupies the seat. It has been possible in a crowded cosmopolitan city like Paris to absolutely prevent the practice. In every tram car and omnibus a placard is conspicuously displayed, bearing the words: *Il est interdit par mesure d'hygiène de cracher sur le parquet* (It is forbidden as a hygienic measure to spit upon the floor). Why should it not be just as possible in our own communities, where the communicability of tuberculosis through the medium of dried sputa is known to every newspaper reader, and where there are health boards whose duty is to prevent the spread of this disease by the direct transference of the foul mess of tobacco juice, saliva and morbid expectoration to the underclothing of innocent women? If this is not done it must be admitted that sanitary endeavor in America finds a limitation wherever a car fare may be obtained from a creature whose habits are no matter how disgusting and obnoxious, and that provisions for the public welfare are impracticable if wealthy corporations negative them. There can be no better missionary service than to preach the gospel of cleanliness and godliness to the enriched directors of street railways, who are as criminal in their indifference to this one provision of public decency and public health as the builders of unsanitary dwellings or the venders of unwholesome food. A league of zealous, determined men and women could profitably serve both God and man by removing at least this one existing limitation to the sanitarian's work.

THE PATHOLOGY AND ETIOLOGY OF THE DISEASES OF THE ACCESSORY CAVITIES OF THE NOSE.

Our knowledge of the morbid processes in the accessory nasal cavities is very limited. The inaccessibility of these places is no doubt largely responsible for this fact. To ZUCKERKANDL, the anatomist, belongs the credit of having directed attention to the diseases of these cavities by the publication of the well-known "Normal and Pathological Anatomy of the Nose and its Pneumatic Appendages," in which are found many illustrations of interesting morbid processes. A very important step in advancing the

range of observations concerning the anatomic changes in these spaces was introduced by HARKE,¹ who devised a practical method of gaining access to the interior of the nose and adjacent cavities during post-mortem examinations without any disfigurement of the face of cadaver. HARKE's method consists, in brief, of the following steps: After removing the brain in the ordinary method the soft parts are reflected anteriorly down to the root of the nose, posteriorly down below the foramen magnum. Then the floor of the skull is divided in the median line by means of a keyhole saw from the nasal bones in front to the occipital foramen behind, keeping as nearly as possible to the median line. Now the two halves of the skull are separated by means of a broad chisel and mallet, and as the nasal and pharyngeal cavities come into view, the pieces of mucous membrane may be cut across with the knife or scissors so as to prevent further tearing. With the hammer and chisel the axis may be divided. The two halves of the skull are still connected by the nasal bones, the maxillary process of the upper jaw and the palate; strong traction will separate these bony connections without injury to the soft parts, and the lateral halves of the skull will yield sufficiently to allow inspection down to the vocal cords. The partitions between the accessory cavities are readily cut away with scissors.

By means of this method HARKE examined some four hundred noses, and his "Contributions to the Pathology and Therapy of the Upper Respiratory Passages"² forms a very valuable addition to ZUCKERKANDL's work.

In order to study more closely the relations of general affections to the pathologic processes in the nasal accessory cavities as well as the histologic changes of the mucous membranes of the latter and the nature of the etiologic agents at work in their inflammatory diseases FRÄNKEL,³ of Hamburg, made a systematic and broad examination of these localities in a large number of autopsies. Among fifty cases examined exclusively for the purpose of showing whether the normal mucous membrane of the accessory cavities of the nose is free from bacteria or not, FRÄNKEL found only twenty-eight to be available for this purpose, *i. e.*, normal, and of these twenty-eight only thirteen were completely sterile. The remaining fifteen showed microorganisms to be present most often in the antrum of Highmore (eleven times), then in the frontal sinuses (six times), and least often in the sphenoidal sinuses (five times). Without going into complete details it may be said that the following microbes were found in the order of frequency in which they are named: The diplococcus lanceolatus, the yellow pus coccus, an organism morphologically like the bacillus diphtheriæ, the

¹ Virchow's Archiv., Bd. 125, Heft 2.

² Wiesbaden, 1895.

³ Virchow's Archiv., Bd. 113, Heft 1.

bacillus coli communis, and two hitherto undescribed bacilli. The *diplococcus lanceolatus* was found oftener than the others in each of the cavities; it was frequently single but also in company with some of the other microbes named, most often with the pus cocci. From the results of this phase of his studies FRÆNKEL concludes that in a large number of normal accessory nasal cavities there occur microorganisms which, we know, play an essential rôle in the inflammatory processes of the respiratory tract. In 40 per cent. (sixty-three cases) of the post-mortem examinations of the nasal cavities there were morbid changes present. In thirty-seven cases the process was limited to a single cavity. The antrum of Highmore thirty times (right seventeen, left thirteen), and the sphenoidal sinuses seven times. In eighteen cases two cavities were involved at the same time, both antra of Highmore seven times, one sphenoidal sinus and antrum of Highmore eight times, both sphenoidal sinuses once, one sphenoidal sinus and one frontal sinus once, and frontal sinus and antrum of Highmore once. In six cases three cavities, and in one case four, and in one case all six accessory cavities were involved. The general result may consequently be said to show that the antrum of Highmore furnishes by far the largest contingent of cases of disease of the accessory nasal cavities, then comes the sphenoidal sinuses while the frontal sinuses furnish but a small number of cases. Systematic examinations like this are the only means that would lead to any definite information concerning the relative frequency of disease in these various centers mentioned.

In regard to the nature of the pathologic processes present FRÆNKEL found that inflammatory or exudative changes are by far the most frequent. The exudate may be serous, mucous, muco-purulent, purulent or sanguinous. The quantity is variable. In quite a number of the cases the mucous membrane contained cysts which most likely were due to retention. ZUCKERKANDL⁴ doubted the ability of the mucous membrane of the antrum of Highmore to form pseudo-membrane, but one observation of FRÆNKEL's shows that it may form fibrinous false membrane. The histologic changes in the mucous membrane most frequently present were those more or less characteristic of inflammation. The microbe most frequently found in the diseased cavities was, again, the *diplococcus lanceolatus*, quite frequently in association with other germs, especially the pus microbes. Various members of the latter group were also found alone. Once the influenza bacillus was demonstrated to be present, the cause of death being pneumonia in the course of influenza. The colon bacillus was found once. A *bacillus mucosus capsulatus*, FRÆNKEL, hitherto undescribed, was also found in a few cases. The action of these various microorganisms is incon-

stant and the character of the changes present does not allow any inference as to the kind of infection at hand. The same microbe may cause different forms of disease.

Among the general conclusions arrived at by FRÆNKEL may be mentioned that these accessory cavities of the nose are so frequently the seat of disease that more attention must be paid to their condition than has hitherto been done. Suppurative processes in any of these cavities always form a menace to the health and life of the individual. Both HARKE⁵ and FRÆNKEL call our attention to the fact that in atrophic and marasmic children it is not unusual to find chronic suppuration in the antrum of Highmore that might be regarded as the source of a chronic intoxication. FRÆNKEL has also observed a case in which a chronic empyema of the frontal sinuses was followed by thrombo-phlebitis of the longitudinal sinus and consecutive pyemia. In general infectious diseases as, for instance, fibrinous pneumonia inflammatory conditions of secondary origin may arise in the nasal accessory cavities, which may become chronic and in turn act deleteriously upon the whole body. While ZUCKERKANDL⁶ regards the diseases of the accessory cavities as oftener secondary to nasal affections HARKE and FRÆNKEL both conclude that in the main the acute inflammations of the accessory cavities are entirely independent of the affections of the nose proper. It is a significant fact in support of this view that FRÆNKEL in his investigations found only nine cases of disease in the main nasal cavity and that in five of these the mucous membrane of the accessory cavities was normal. It is also a quite general belief that the most frequent cause of empyema of the antrum of Highmore is the extension of morbid processes connected with the teeth or their alveoli. This view is upheld by ZUCKERKANDL. HARKE and FRÆNKEL both find, however, that the frequency of the dental origin of inflammation in the maxillary sinuses has been greatly overestimated. Out of all his cases FRÆNKEL found only two in which the process in the antrum could be referred to the teeth. FRÆNKEL consequently makes the general statement that in the majority of instances inflammation of the maxillary sinuses develops independently of pathologic changes in the neighborhood and that certain general diseases play a much more important part in its pathogenesis than has been assumed. These anatomic studies also seem to show that the relation of nasal polypi and of inflammatory swellings of the infundibulum to the diseases of the antrum is the reverse of the usual teachings in so far as no evidence has been brought forward that polypi and the like are secondary to disease in the antrum, which is the view usually held by the clinicians. Finally, attention is also directed to

⁴ Loc. cit.⁵ Loc. cit. ⁶ Loc. cit.

the fact that the inflammations in the mucous membranes of the accessory nasal cavities do not seem to give rise to lesions of the bones unless specific processes like tuberculosis, syphilis, or leprosy are present. A correct understanding of the etiologic and anatomic factors and conditions will undoubtedly be of the greatest benefit in the treatment and the prophylaxis of the morbid processes that have been referred to. When the interest of the specialists and of clinicians in general in these common forms of disease in the accessory cavities of the nose has been awakened by such comprehensive investigations as those of HARKE and of FRANKEL, there can be no doubt but that much will be brought to light that will be of importance in the symptomatology and early diagnosis of these affections.

HOSPITAL CORPS EQUIPMENT AND DRILL.

During the past week two orders have been published by the War Department bearing on the equipment and efficiency of the hospital corps. One of these orders provides that when detached for service in the field during Indian wars, or when left with the sick and wounded under circumstances which justify the expectation that their rights as non-combatants under the Geneva Convention will not be recognized, commanding officers will issue to members of the hospital corps revolvers or other available fire-arms. The meaning of this is obvious, to afford them the means of protecting themselves and the wounded under their care. It affects the equipment of the men under certain conditions of active service; but the sentence which follows will be regarded by many as containing the essence of the order: "With these exceptions no side arms will be issued to members of the hospital corps." This modifies their present equipment by removing the sword or saber of the non-commissioned officer, and the heavy knife worn by the men since the organization of the corps. The sword is not required by the hospital steward as a badge of authority. It is a useless relic of a former age and an encumbrance at all times, and particularly in the discharge of his duties to the sick and wounded, while the knife of the enlisted man, a cross between a Mexican machete and a sword bayonet, has been merely so much useless weight for him to carry on active service.

The second order referred to is one convening a board of officers to revise the drill regulations of the hospital corps. The board consists of MAJOR JOHN VAN R. HOFF, MAJOR VALERY HAVARD and CAPTAIN JULIAN M. CACELL, Medical Department, U. S. Army. All these officers have had much experience in the handling of hospital corps companies. It is understood, however, that no radical change in drill methods is intended, the main object of the revision being to bring the drill regulations into harmony with the

litter and sling, model of 1895, recently approved by the Surgeon-General. The present regulations were prepared for a litter with an attached sling, but, in the model of 1895, the sling is an individual sling worn on the shoulders of the bearer, its looped ends merely requiring to be slipped on and off the handles of the litter in the various movements. The convention of this board does not mean that present drill methods are unsatisfactory, although no doubt the board will embody in its revision all the changes and improvements that several years of experience in the method have suggested as desirable.

CHILD STUDY.

There exists in the city of Chicago, and similar organizations can probably be found in other centers, a society for the promotion of child-study. While the leading idea of such study is undoubtedly psychology, the subject is suggestive in a medical point of view, and may well be worth an editorial comment in a journal that only deals with psychologic questions in their specially medical aspects and bearings.

There is no period in life when mental and physical development is as rapid as in childhood, and therefore there is none more interesting in a physiologic as well as in a psychologic point of view. Physicians have studied children in their pathologic peculiarities; pediatrics is a recognized medical specialty, but it is a reasonable question whether it might not be as well to widen its scope and take into it some attention to the unfolding of the intellectual life in its beginnings. The skilled medical practitioner can better than anyone else first take note of and point out the way of correcting the morbid traits and tendencies that lead to physical and mental degeneracy, he can study and estimate the hereditary influences and advise how they are to be met, and can instruct the mother in what should be the most fascinating pursuit of her life, the proper method of studying the development of her offspring. These are the possibilities of his profession; we do not say they are generally or even often realized.

Considering, however, only the physical side of the question of child study, it is not a credit to our profession that while the studies of the growth and the physical data of childhood are being taken up by laymen and educators it should be in any degree behind them in the same line of investigation. While physiologists were ahead of psychologists in recognizing the value of knowledge of the earliest developmental processes and conditions in the study of functions, it seems now that the newer school of psychologists, enlightened by the data of physiology, may in their turn put practical medicine under obligations for important facts and deductions. Sometimes they may be on the wrong track, or on one that is uncertain, but they are always suggestive and instructive in their modern methods.

The practical value of child-study should be evident to anyone. The old saying that "as the twig is bent, the tree is inclined," so often quoted with a moral application, has a physical and intellectual appropriateness as well. Hence every real acquisition of fact or legitimate theory in regard to the bodily or mental development of children has its value, and there is an ample store of such facts yet to be acquired. At the present time we may take, for example, the theories of mental and bodily degeneracy that are just now so much to the fore, and it is easy to see that they can only be proven or disproven by taking into consideration the earlier conditions of the individual and the influences that affected his development. The question as to the existence of such a type as the "born criminal" is, as might be inferred from the term itself, one that can only be settled by the study of the development and beginnings as well as the finished type; in short, by a study of the morbid tendencies and moral development of the child. As an almost purely medical line of investigation, and not the least important may be mentioned that of heredity in children, which can hardly be studied by anyone so well as by the general practitioner—the family physician. GALTON has laid down a plan for this line of research in his "Natural Inheritance" that is at least worthy of some consideration. The amount of valuable facts and statistics that could be obtained from a general interest in this study in the medical profession can hardly be over-estimated. Other interesting questions are some of those of the origin of insanity, especially those forms that seem to be more or less dependent upon errors of education and training and management of developmental periods, and here the well directed attention to the facts of early life will be found to be productive of valuable results. It is not meant to be understood that these questions are neglected by physicians, but more systematic study of all the stages of early human development is needed to fully elucidate them.

It is noteworthy that this whole subject of child-study is comparatively of modern development. If we look over the bibliography as given in the report of the Commissioner of Education for 1892 and 1893, just issued from the Government press, we find comparatively few works dating back more than twenty years, and most of the papers bearing directly on the subject have appeared within the last decade. While it is likely to continue to be for the most part a specialty of educators and psychologists, it is to be hoped that our profession will not too much neglect the special opportunities it has in this particular direction.

A special telegram to the JOURNAL from DR. R. HARVEY REED informs us the Practice of Medicine Act passed the Ohio State Senate February 19. The quacks will now have to "move on." The medical profession of Ohio are to be congratulated.

CORRESPONDENCE.

"Nine Years of Diphtheria."

To the Editor:—The JOURNAL of February 15 contains a remarkable article with the above title. If you will allow me sufficient space I would like to call attention to some of its remarkable statements.

1. The author has used the serum treatment in a series of nearly three hundred cases, both as a curative and a preventive agent *during the past year*.

2. In December, 1894, the disease appeared in its *most malignant form* and has *continued ever since*.

3. During September and October of one year he treated 123 cases *without a death*.

4. Since Jan. 1, 1895, he has treated fifty-seven cases varying from the *most malignant* to moderately severe cases, *none having been mild*; there were two deaths with fifty-five recoveries, a mortality of *less than 4 per cent*.

The remainder of the article contains many extravagant statements equal to the foregoing but I have not the time to devote to them. After reading the article referred to, curiosity led me to make some investigations. By referring to a map of Indiana I noticed that the city of Vevay, Ind., was situated on the Ohio River, about midway between Louisville and Cincinnati; that the county in which city is situated is not marred by a single mile of railroad; that its only communication with the outside world was by way of the Ohio River; that it was one of the oldest settlements in the State; that the population of the city in 1880 was 1,884, in 1890 it was 1,663; that it has no children's hospital or general hospital, except an orphanage and poor asylum. So the statistics of the article must be made up from cases in private practice. Vevay is credited with seven other physicians than the author of the article in question.

Now as to statement No. 1. Three hundred inoculations in one year; this is more than one-sixth of the entire population. Surely the Doctor must have a formidable grip on that community if more than one-sixth of all ages combined resort to him for curative and preventive inoculations; possibly the Doctor holds his patronage by inoculation! (Other doctors take warning.) In these 300 cases he has used from 200 to 4,500 units (Behring) each injection and has repeated 200 to 600 units every six hours as required. For a town of 1,663 inhabitants Vevay is the boss market for antitoxin. Possibly this may account for the scarcity of Behring's antitoxin in Berlin.

Statement No. 2. Malignant diphtheria existing in a city of 1,663 for an entire year is quite a reflection on the local Board of Health, to say the least. Reference to the records of the State Board of Health will possibly define the character of this long-continued epidemic; and as Dr. D. has saved three hundred what have the other seven physicians been doing?

Statement No. 3. One hundred and twenty-three cases treated during the months of September and October without a death. Over sixty cases a month, in private practice, in a city of 1,663 inhabitants, and seven other physicians to hear from. We will take it for granted that the seven were not very busy, but it must have made Dr. D. hump himself to attend to that many cases of diphtheria in addition to his other patients. This was called a mild epidemic but no doubt as to the diagnosis is entertained; the writer of the article did not say, but we infer that he made a bacteriologic test in every case, and confirmed the diagnosis, for he makes the statement that the discovery of the *Löffler-Klebs bacillus* has forever settled the controversy and we are satisfied he wished to be exact. These 123 cases, we suppose, antedated antitoxin in his practice.

Statement No. 4. Fifty-seven cases in one year with two deaths, under the use of antitoxin. (Seven other physicians

still to hear from.) Enthusiasts often make extravagant claims for any treatment that is new, but Dr. D. has had better success than any writer of my acquaintance, and I am sure he deserves it all for he seems to have pinned his faith to serum-therapy alone, and such devotion will assuredly be rewarded. Serum-therapy, still in its infancy, has burdens enough of its own to bear: it seems a pity that it should be loaded down by one of its supposed friends by an article in its behalf as illogical, unreasonable, unscientific and misleading as the one above referred to.

In the State of Indiana, reports of contagious diseases are required by law. Did Dr. D. make said reports and are they safely on file in the Health Office for future reference, or is the Doctor liable to fine for failure to report them? Such valuable statistics should not be lost. I am somewhat surprised that the JOURNAL admitted the article to its columns. CRITIC.

Abortion Legalized.

CLINTON, IOWA, Feb. 12, 1896.

To the Editor:—It is of interest to us to be posted on the laws and decisions that relate to the profession. A respectable woman of this city called on a female practitioner stating that she had a babe five months old and was again pregnant, and very earnestly desired to be relieved of it. A soft catheter was introduced by a director or sound. The director was withdrawn and the catheter was left behind. After waiting seven or eight days as was proved, the "doctress" called on a medical man telling him she had introduced a soft catheter into a woman's uterus and could not get it out. He told her it would undoubtedly be expelled: if not, to dilate the os and reach for it with a pair of placenta forceps, that he lent her.

In the evening she returned saying she was in trouble and wished him to see the woman. He called at the house and on examination found a length of intestine protruding from the vulva, bearing the marks of the forceps. The patient said she had endured the torments of the damned for a week. The doctor at once called in three other physicians and as soon as convenient made a section, opening the abdomen, finding the catheter among the intestines with abundant signs of inflammation. The uterus was cut through in several places by a curette, through one of which the intestine had been drawn. The woman did not rally from the operation. The coroner was called; the "doctress" acknowledged the introduction of the instrument, with intent. The verdict was rendered accordingly. Prosecution followed, for malpractice and murder. Being a woman, by a quibble of the law she was admitted to bail. After passing over several terms the case came up for trial. All the facts were proved. Witness for the defense testified that it was done at the woman's urgent request and that due care and diligence had been taken afterward. Counsel for the defense asked the several witnesses if such was not their practice; this was of course overruled, but the benefit of the doubt was put before the jury.

The Judge charged, that if they found the act done in contravention of the law, they were to convict: that if it was done with good intent and that due diligence and care had been used according to the best of her ability they could modify their verdict. The jury retired and on first count stood ten for acquittal. After being out for several hours the refractory ones came over and a verdict was returned of not guilty.

The courtroom was so crowded with women during the trial that the door was closed shutting many of them out. The sentiment among them was that the prosecuting witnesses were addicted to the same practice and were actuated by malice or envy. Mr. Tait was quoted, as having heard that rupture of a diseased uterus had taken place spontaneously. After the trial an autograph letter of Tait was published in the local papers thanking some one for reporting a case of spontaneous rupture of a uterus.

It seems to us that this lets down the bars and gives a quasi-legal sanction to the practice. To our credit, however, we may add that the "female practitioner" was not a graduate but had received a license from the State Board of Health of Iowa.

Very truly yours,

M.D.

Diphtheritic Treatment.

ST. PAUL, NEB., Feb. 14, 1896.

To the Editor:—In the JOURNAL of Feb. 1, 1896, we notice an extract from the *New York Medical Journal*, entitled "Diphtheria *sine* Antitoxin," credited to Dr. O. B. Douglas. We read this short article with much interest, as it seems to be very nearly a concise reproduction, in meaning at least, of a paper contributed by myself on the treatment of diphtheria, to the *Southwestern Medical Gazette* for March, 1887, from which the following is quoted. In speaking of the local application of irritants such as tinc. ferri chlorid, we said: "In the first place we get the irritating effect on the diphtheritic abraded surfaces of the fauces and pharynx, which is anything but desirable, as it aggravates the inflammation by its constricting and irritative properties." "I have used locally a very mild gargle or spray of glycerin, carbolic acid and rosewater." "To sum up: My success I have attributed to the use of aconite and belladonna. Their use has been kept up for from one to four days and governed by the urgent symptoms." "The use of aconite in diphtheria will to many appear as a gross error, but when we consider its many desirable properties, as the lowering of temperature, relieving the engorgement of a part by dilating all blood vessels, thus subduing congestion and inflammation, that it is a great eliminant both of liquids and solids (probably in that way acting as a specific in diphtheria by eliminating the poison), and that its depressing effects are overcome by belladonna, its efficacious use seems to me very rational." "Alcoholic stimulants injudiciously administered in diphtheria, is a very routine practice, yet given in appropriate doses at the proper time, great good may be achieved by their use. In the early stages I venture to say that nine cases out of ten are better off without any stimulants."

Since the above was written we have employed this treatment in upward of six hundred cases, in what was clinically proved diphtheria, with the best possible results. Indeed, the mortality has been so low when the patients were seen early that the use of antitoxin would almost seem superfluous.

While we still employ the aconite-belladonna treatment, yet we must beg to differ with Dr. Douglas. We are thoroughly "converted" to the "faith" in antidiphtheritic serum. Cases in our hands, bacteriologically proved diphtheritic, brought under the influence of this agent, do certainly become convalescent in half the usual time required under any other form of treatment. To my mind, judging from clinical observation, the treatment of diphtheria to-day, *without* the use of a reliable serum, can not be too highly censured both from a medical and a humane standpoint.

O. GROTHAN, M.D.

The Character of the Anti-Vivisectionist.

CINCINNATI, OHIO, Feb. 15, 1896.

To the Editor: Among your comments on the vivisection bill of Mr. McMillan, on p. 297 of the issue of the JOURNAL of February 8, you make use of the following language:

"In the absence of knowledge of the subject, no one should chide these good hearted men and women, etc.," (no need to quote the remainder). Now my dear doctor, the "good book" (both versions) contains the following passage, "Fools rush in where angels fear to tread," in line with this statement is the fact of experience that ignorance will criticise, while knowledge is weighing evidence. It is also a known fact that an exaggerated idea of the specific individuals, qualifications and *ego*, is the prompter for the rendition of judgment by that individual, who

thinks what he or she *thinks*, is necessarily *law*. It is a well-established principle of justice, and common sense as well, that evidence shall precede a verdict, and when we refrain from "chiding" those who reverse the order, we are guilty, at least, "after the fact." I have paid considerable attention to the matter, and my personal experience has shown me that those individuals who deprecate harsh measures with poor "Lo," are in every case, people who are intimately acquainted with the "Leatherstockings" of the novelist, but who have not even a slight acquaintance with a veritable copperskin except as civilized temporarily, for dime museum purposes; and that the most active in behalf of suffering hearts, find no time for efforts in behalf of suffering humanity. There are exceptions possibly, but the above may be formulated in a general law. Why individuals who are intensely humane in one direction are equally cruel in others is a question not difficult to answer, but is not germane to the present subject. True advancement has ever been retarded by the "snap judgment" of the ill-informed, especially those who have a smattering of technicalities and consider them the science. People who offer judgment upon matters which have not been fully considered by them as to *pros* and *cons*, should not only be *chidden*, but forcibly sat down upon in *all* cases. *All* persons are "laymen" with regard to any point of which they have not made a definite study, whether it concerns medicine, or political economy, or any other subject, and it is the constant attempt made by many proficient in *one* matter to assume the judicial ermine as to *all* matters, which retards the spread of real truth. The foregoing is my "say so" and I presume that having said it, the rest of the world will accept, and keep on judging as usual.

Yours truly,

J. WINCHELL FORBES.

1128 Locust Street, Walnut Hill.

BOOK NOTICES.

The Year-book of Treatment for 1896. A Critical Review for Practitioners of Medicine and Surgery. 12mo, 476 pages. Cloth, \$1.50. Philadelphia: Lea Brothers & Co., Publishers. 1896.

This is the twelfth issue of this annual, and it represents the work of twenty-five well-known English contributors, who have culled from contemporaneous medical literature the material for the volume, which thus constitutes a pretty fair epitome of the medical writing of the year.

The Principles of Bacteriology: A Practical Manual for Students and Physicians. By A. C. ABBOTT, M.D., First Assistant, Laboratory of Hygiene, University of Pennsylvania, Philadelphia. Third edition, enlarged and thoroughly revised. 12mo, 492 pages, with 98 illustrations, of which 17 are colored. Cloth, \$2.50. Philadelphia: Lea Brothers & Co., Publishers.

In our notice of the second edition of this book (see this JOURNAL, Oct. 6, 1894), we took occasion to say that it was "in every way worthy of the success it had met with, and is destined to become a general favorite."

The edition now before us is gratifying evidence of the correctness of the judgment then expressed. It has been brought quite up to date, and will doubtless retain its popularity with students. We commend it as a trustworthy guide.

Studies from the Department of Pathology of the College of Physicians and Surgeons, Columbia College, New York. Vol. IV, for the collegiate year 1894-1895. Reprints.

Dr. Prudden states in the preface to the volume, that "it has seemed to us that by this form of publication—first the wider circulation which current medical journals afford and the subsequent grouping together of reprints—the aims of such varied studies are more certainly accomplished than they would be by a special departmental or college publication."

Our readers will we are sure agree with Dr. Prudden in his views, and feel that they are the gainers by the prompt trans-

mission through the medical press of the conclusions of the laboratory experiments. Those wishing to preserve them separately have the opportunity. The volume is well illustrated.

Annual Report of the Supervising Surgeon-General of the Marine-Hospital Service of the United States for the Fiscal Year 1894. Washington: Government Printing Office. 1895.

This report, which is handsomely illustrated, details the operations of the Service for the year ended June, 1894, and conveys the usual professional information contained in the necropsy reports, and the carefully compiled statistical tables which have constituted a valuable feature of these reports for many years. The operations of the quarantine service for the period mentioned are fully set forth, and the continued evolution of that branch of the Service is manifested in the voluminous reports and regulations reprinted in this volume.

As these operations passed into history nearly two years ago, it is not practicable here to discuss situations which no longer exist, or which may long ago have been modified by changes in regulations. As a contribution to the governmental history of the year 1894, the report is an extremely interesting one.

Transactions of the American Surgical Association. Volume XIII. Edited by DEFOREST WILLARD, A.M., Ph.D., M.D., Recorder of the Association. Royal 8vo, cl., pp. 516. Philadelphia: William J. Dornan. 1895.

This volume contains, beside the address of President Dennis, articles by Drs. Gerrish, Homans, Connor, Wight, McGuire, Gerster, White, Mears, Gay, Weir, Deaver and Frese, Carmalt, Sayre, Roberts, Bradford, Park, Mastin, Wharton, Burrell, Packard, Fenger, Weeks, Norris, Mixter, Elliot, MacCormac, Hart, Souchon, Richardson and Bryant, names sufficiently well-known to insure the excellent quality of the essays. The report of the Committee on Necrology includes biographical sketches of the late Prof. William T. Briggs, of Nashville, Prof. Albert B. Miles, of New Orleans, Professor Thiersch, of Leipzig, Mr. A. E. Durham, of London, and Prof. Aristide A. S. Verneuil, of Paris.

The volume is handsomely printed and a worthy companion to its predecessors. The next meeting of the Association will be held at Detroit May 26, 1896, under the presidency of Dr. Tiffany, of Baltimore.

Syphilis in the Middle Ages and in Modern Times. By DR. F. BURET, Paris, France. Translated from the French, with notes, by A. H. OHMANN-DUMESNIL, M.D., Professor of Dermatology and Syphilology in the Marion Sims College of Medicine; Consulting Dermatologist to the St. Louis City Hospital, to the St. Louis Female Hospital; Physician for Cutaneous Diseases to the Alexian Brothers' Hospital; Dermatologist to Pius Hospital, to the Rebekah Hospital, to the St. Louis Polyclinic and Emergency Hospital, etc. Being Volumes II and III of "Syphilis To-day and Among the Ancients," complete in three volumes. 12mo, 300 pages. Extra cloth, \$1.50 net. Philadelphia: The F. A. Davis Co., Publishers, 1914 and 1916 Cherry Street: Chicago: 9 Lakeside Building.

The interesting historical study begun by Dr. Buret in volume I is continued in volumes II and III here completed. The painstaking labor has comprised an examination of all literature of the subject, and we can well believe, as the author states, three years were consumed in the compilation of the first volume alone.

Dr. Dumesnil has very lucidly and accurately translated the work and thereby laid his countrymen under a permanent obligation. We notice an error in spelling the name of Paulus Ægineta on page 3, and repeated twice on page 5.

The material which Dr. Buret has offered as evidence to prove the pre-Columbian existence of syphilis in Europe, can not all be accepted as evidence, but he has produced more than enough that is conclusive, to prove his postulate. After the publication of the manuscripts and documents now unearthed by the author there can no longer be any doubt of the greater antiquity of syphilis on the continent of Europe than old John Astruc was willing to allow it.

Color Vision and Color Blindness. A Practical Manual for Railroad Surgeons. By J. ELLIS JENNINGS, M.D. (Univ. Penna.) formerly Clinical Assistant Royal London Ophthalmic Hospital, Moorfields; Lecturer on Ophthalmoscopy and Chief of the Eye Clinic in the Beaumont Hospital Medical College; Ophthalmic and Aural Surgeon to the St. Louis Mullanphy and Methodist Deaconess Hospitals; Consulting Oculist to the Missouri, Kansas and Texas Railway System; Fellow of the British Laryngological and Rhinological Association; Secretary of the St. Louis Medical Society. Illustrated with One Colored Full-page Plate and Twenty-one Photo-engravings. Crown 8vo, 110 pages. Cloth, \$1 net. Philadelphia: The F. A. Davis Co., Publishers, 1914 and 1916 Cherry Street; Chicago: 9 Lakeside Building.

This book contains ten chapters as follows: 1. Historical Sketch; 2. Physiological Anatomy of the Retina; 3. Physics of Light-color Sensations; 4. Theories of Color Perception; 5. Color Blindness; 6. Methods for Detecting Color Blindness; 7. Pseudo-isochromatic Tests, Contrast Tests, Special Tests; 8. Acquired Color Blindness; 9. Pennsylvania Railway Company's Instructions; 10. Oliver's Tests, and General Remarks.

The book applies exclusively to railway employes, but it does not touch upon the subject of its enforcement by the Treasury Department of the Government, nor are the statistics of the Public Service, although easily accessible, touched upon. So far as its scope extends, the book is an excellent one and will be of use to all railway surgeons.

Transactions of the New Hampshire Medical Society at the one Hundred and Fourth Anniversary, held at Concord June 3 and 4, 1895. Concord, N. H. Printed by the Republican Press Association.

One of the important functions of the medical society nowadays is the cultivation of the art of public speaking, and if our readers are in any doubt about the ability of the physician as an after-dinner speaker, let him make a collection of the post-prandial gems that emanate from the different members of our profession while in reunion at the annual society dinners, and he will be convinced that there are none more able than our doctors. But the annual dinner is not only productive of oratory, but of good fellowship, and it strengthens the ties of professional *camaraderie* by those of social sympathy. The publication of the remarks made at these reunions, naturally stimulates one's pride in his profession, and leads to stronger attachment to one's medical society than if the bald terms of science were alone used, and the dry topics of tedious experiments alone considered. The beer is stale without its froth, and the scientist without humor or sociability is like an icicle, which one may indeed admire, but only at a distance. Moreover, a pleasant manner and air of freedom from care increases the power of the scientist over the people who are otherwise prone to vote him always a bore, and perhaps at times an ass as well.

We were led into these reflections on reading the excellent speeches printed in the New Hampshire Transactions for 1895. And the many valuable scientific papers printed in the book are not one whit less instructive because an account of the annual dinner is included.

NECROLOGY.

DR. CORNELIUS GEORGE COMEGYS died at his residence, 524 West Seventh Street, Cincinnati, February 10, at 1 o'clock A.M., after an illness of one month of la grippe complicated with nephritis. From his autobiography as printed in the "Physicians and Surgeons of America," we learn that Dr. Comegys was born July 23, 1816, in Cherbourg, the family estate in Kent County, Delaware. He was a descendant of a German-Holland family that was naturalized in Kent County, Maryland, in 1673, being a son of Cornelius Parsons Comegys, Lieutenant Colonel of State troops in the War of 1812, and Governor of Delaware, 1838-41. His mother, Hannah, was a daughter of John Marin, a soldier in the Revolution; his brother, Joseph Parsons Comegys, LL.D., was Chief Justice of Delaware, 1876-92; also a United States Senator, 1856. Benjamin Bartus Comegys, LL.D., is President of the Philadelphia National

Bank and a trustee of the Girard estate. Dr. Comegys was educated chiefly in the Dover Academy. He began life as a teacher in a district school; then he went to Indianapolis, Ind., for employment in the United States Engineer Corps, constructing the National road to St. Louis; at length he became Cashier-clerk in the State Bank of Indiana, removed to Lawrenceburg to become a cashier; finally took part in a large flouring manufactory; this proving disastrous, he resolved to abandon a business life and study medicine, his original purpose. In the meanwhile he had studied chemistry, physics, astronomy, geology, psychology and political economy. He removed to Philadelphia and matriculated in the University of Pennsylvania, Department of Medicine, under the preceptorship of W. E. Horner, professor of anatomy and dean of the medical department. He took two winter courses and one summer course—daily clinics in the college and Pennsylvania Hospital, and a course of French under Delacroix; was graduated in March, 1848, and began practice in Philadelphia. In the latter part of the year he located in Cincinnati.

After the epidemic of cholera in 1849, in which he took a

most active part and attended a large share of cases, he went to Europe to complete his education. He there attended Guy's Hospital under Cooper, Addison, Golding, Bird, Gull and Oldham. While in Paris he was associated with Charcot, Andral, Velpeau, Trousseau, Rostan, Nélaton and Dubois. On his return to Cincinnati in 1852, he gave a course in anatomy in the College of Physicians and Surgeons, then joined in the organization of the Miami Medical College as professor of the institutes of medicine, and continued until the fusion with the Ohio Medical College in 1857, where he was allotted the same chair, and, additionally, clinical teacher in the medical staff of the Cincinnati Hospital, at that time under the control of the Medical College of Ohio. He resigned his chair in the college in 1869, but retained his hospital position for over thirty-five years, and for the past seven years has been President of the staff. It was at his suggestion that the department of pathology was created by the board. He also proposed a system of bedside instruction in all the departments, to small groups of advanced students. He was one of the founders of the Academy of Medicine and twice served as President; was a mem-

ber of the old Medico-Chirurgical and the Cincinnati Medical Society; he was a member of the AMERICAN MEDICAL ASSOCIATION, of the Mississippi Valley Medical Association, honorary member of the Philadelphia College of Physicians, of the Delaware State Medical Society, of the Western Reserve Historical Society of Ohio, the Ohio Historical and Philosophical Society and the Cincinnati Literary Club. His chief publications are translations of Renouard's "History of Medicine," 1855; Charcot's "System Diseases of the Spinal Cord," 1881. His medical papers have been numerous, among which are: "Conservative Value of Fever and Inflammation," "Transactions of the Cincinnati Medico-Chirurgical Society," 1849; "Etiology and Treatment of Phthisis Pulmonalis," "Transactions of the Ohio Medical Society," referred to in the American edition of Watson's "Practice of Medicine," and in Copeland's "Medical Dictionary," "The Pathology and Treatment of Asiatic Cholera," 1866, Blackman and Parvin's Cincinnati *Medical Journal*; address before the Alumni Society of the University of Pennsylvania, 1875, published by the society. He maintained the necessity of reform in medical education in the line of entrance examinations, a longer period of instruction, especially for clinical study and laboratory work, which, he has been assured, promoted the adoption of the great forward movement which has distinguished the course of the universities since 1875; he proposed at the same time the encouragement of the practice by physicians of forensic medicine, which he argued would secure a higher form of judicial decisions and serve to advance the medical profession to higher rank and usefulness in the State. After the battle of Fort Donnellson and Shiloh he volunteered his services and had charge of the boats fitted up for the relief of the sick and wounded.

His most conspicuous work of the past two years was as Chairman of the Special Committee of the AMERICAN MEDICAL ASSOCIATION to secure an act of Congress for the creation of a Department and Secretary of Public Health on a parity with other departments of the Government. He married in 1839, Miss Rebecca, daughter of Governor Tiffin, the first Governor of Ohio and United States Senator. Their children are: Edward Tiffin, A.M., M.D., Major and Surgeon in the United States Army; William H., M.D., Major in the pay department of the United States Army; Charles George, B.S., B.A., practicing law in this city: Ellen Tiffin and Mary Porter Comegys.

In the death of Dr. Comegys the profession has lost a most beloved and respected member, the city of Cincinnati a most valued citizen, and the younger element of the medical profession a staunch supporter. Dr. Comegys was a man who could always be relied upon to fight for the right and his constant and enthusiastic endeavors were to elevate the profession of medicine to the highest possible standard from both an ethical and scientific standpoint. Dr. Comegys belonged to the real school of chivalry and was, under all circumstances, a gentleman: his helping hand was always extended to assist the poor and the young man who was ambitious and endowed with noble principles. He was one of the giants of our time and he died in harness, for up to the day of his being stricken he was at his work and keeping abreast of the progress of the science of medicine with as much vim and familiarity with all discoveries and theories as the most ardent worker among the rising generation. In the sick room Dr. Comegys was the dignified and comforting visitor whose presence shed light to the clouded brain, encouragement to the disconsolate: peace to the troubled; and benefit to the afflicted, and his expressions of hope and comfort to the one who was crossing the dark river were like rays of sunshine appearing through the deepest gloom. The Cincinnati Academy of Medicine held a special meeting February 11, and adopted the following resolutions upon the death of Dr. Comegys:

The medical profession is assembled to-day to express a last word in memory of their late associate, Dr. C. G. Comegys.

He was no ordinary man. For forty-eight years he has been a notable figure, not only in his profession, but as a citizen of pure life, of honest purposes, serving the public faithfully and with great ability in various positions.

In all of his relations with us, his professional brethren, he was a gentleman, moved by the spirit of doing unto others as he would have them do to him. He detested everything that savored of the empiric.

A man of gentle, liberal spirit, he was charitable and forgiving. He was, indeed, the friend of his profession, esteeming its object to prevent disease and to do good to all. He was the friend of young men, and by his words of encouragement and his example did much to aid them. Yes, he did much to elevate the tone of the profession in this city.

Dr. Comegys was a man of superior intellect. He fully exemplified the fact that the strong physician is one whose

mind is not "cabbined, cribbed or confined" by strictly technical and professional reading, but is enlarged by all collateral studies and observation. He very early achieved a prominent place as a practitioner. He was a sound counselor, a good clinician, a clear lecturer and teacher. He was the advocate of higher education for the people and for medical students. He did much by word and deed to further this great object.

He believed his profession in its ability do good mentally, morally and physically, superior to any other. He often spoke of the power of the good, able physician.

He originated the idea of having a Board of Health created by Congress, whose head should be a physician and a Cabinet officer. His idea will yet take form. He advocated that physicians should be representatives of the people in Congress and the State Legislatures.

A man of deep religious convictions, and yet charitable to all, he was dominated by the spirit of walking humbly and acting mercifully, serving Him whom he regarded as his Master and Saviour. He did not believe that it is all of life to live or all of death to die.

He belonged to the time when the general practitioner was not only the medical advisor, but the counselor and friend of his clients. There were giants in those days. Up to a few weeks before his death our departed friend showed the ability and superiority of the general practitioner.

He is an example for every young struggling man. His honesty, his high tone, his noble purposes, his usefulness, should impress his memory on all. Let us cherish it.

[Signed]

JOHN A. MURPHY,
B. P. GOODE,
WM. H. TAYLOR,
JOSEPH EICHBERG.

PROF. JOSEPH JONES.—As we go to press we learn with deep regret of the death of Prof. Joseph Jones, M.D., LL.D., of New Orleans, which occurred February 17.

LEMON WILLARD CLARK, M.D., of Elkhart, Ind., died from apoplexy, February 8. He was born August 1, 1858, and was graduated from Rush Medical College Feb. 21, 1882. He was an active member of the medical societies to which he belonged.

LOUIS Y. WIGGINS, M.D., a veteran physician of Newburg, N. Y., died at that town on February 10, aged 70 years. He was graduated in medicine at the New York University Medical Department, in the class of 1847. He was for a number of years a practitioner of New York city, but for forty years of his professional life he was a popular and successful practitioner of the town above mentioned.

T. H. ELLIS, M.D., of Butte City, Mont., February 1.—Reuben F. Dyer, M.D., of Ottawa, Ill., January 31, aged 62.—F. McClelland, M.D., of Cedar Rapids, Iowa, February 13, aged 66. He was editor of the Cedar Rapids *Times*.—John W. Taylor, M.D., of Shelbyville, Ky., February 8, aged 70.—John W. Kerr, M.D., of Allegheny, Pa., February 9, aged 41.—Daniel Dennison Slade, M.D., of Boston, Mass., February 11, aged 72. He was graduated from Harvard College in 1844, and from the Medical School in 1848; he was Professor of Zoology, and at the time of his death was lecturer on comparative osteology.—J. M. Maloney, M.D., of Allegheny, Pa., February 12, aged 52.—Benjamin Corneille, M.D., of Trempealeau, Wis., aged 29. He was graduated from the Detroit Medical College in 1892.—J. L. Phythian, M.D., of Newport, Ky., February 12. He was born in Johnstown, Pa., in 1833. In 1852 he was graduated from the University of Louisville, and began the practice of medicine in Frankfort until the beginning of the civil war. During the war he was Surgeon-in-Chief of the hospital at Frankfort, and after the war he was appointed Post Surgeon of the United States Barracks at Newport, Ky. He held that position for several years, and was retired in 1873.

PUBLIC HEALTH.

Department of Health of Brooklyn. On February 1, Dr. Z. Taylor Emery took office, for a second term of two years, as the Commissioner of Health of Brooklyn, N. Y. He renominated for his Deputy Commissioner Dr. R. M. Wyckoff, for Register and Secretary Dr. George E. West, and for the Chief of the Bureau of Contagious Diseases Dr. Frederic A. Jewett, for Chief Bacteriologist Dr. Ezra H. Wilson, and for Medical Superintendent of the Department Hospital Dr. A. S. Ambler, Experts in Infectious Diseases Drs. Morton and Duryea.

Changes in South Dakota Board of Health Law.—In 1895 the Legislature of South Dakota enacted a new board of health law. The State board of health is to consist of five members, all of whom shall be resident physicians in good standing, their term of office to be five years, and their appointment to be made by the Governor. It is to meet on the first day of May and November of each year, and at such other times as it shall deem necessary. Its powers are the same as provided by the act of 1891, so far as pertains to the public health, but it is relieved from likewise looking after the protection of the domestic animals of the State. In counties where there are no resident physicians, so that county boards of health can be formed therein, the State board of health is authorized to provide for such county boards under such rules and regulations as it may deem proper.

The Sanitary Management of Floors and Floor Coverings. The editor of the *British Medical Journal* has recently treated of the dangers of household dust, and especially of the improper management of carpets. His line of argument is quoted in the following extract:

To those who know the true inwardness of things, the sight of a housemaid brushing a dusty carpet is suggestive of many evils. The death of Pasteur has reminded the world of what is constantly present in the thoughts of medical men, namely, that while microorganisms are the great producers of disease, dust is the great carrier of microorganisms. Now that we know these things, now that we understand that in the quiet hours of night the germ-laden dust settles down upon the floor, it is distressing to find how little our knowledge is put to practical use, and to see old customs still unchanged, old habits which we know to be destructive carried on, and to find the housemaid on her knees, with her brush and dustpan stirring up dust to the detriment of everyone, and breathing germ-laden particles to her own destruction. It needs but a small amount of common sense to see that if carpets must continue, a thing greatly to be deprecated, they should be rubbed with a damp cloth rather than brushed, and that if, in deference to prejudice, they must be brushed, this should be done by a covered American sweeper with plenty of damp tea leaves. Of all ways of removing dirt from a carpet the worst is by the use of the ordinary short brush, which involves the housemaid's kneeling down in the midst of the dust which she so needlessly creates, and drawing it into her lungs with every breath. For ordinary household use something like linoleum, something which can be washed with a wet cloth every morning, would seem to be the best covering for floors: but if carpets must be, and if it is impossible to teach the present generation the evils of seeking present comfort at the expense of future risks, at least let us remember that carpets may be washed even where they lie: that, till the day of washing comes, a closed sweeper is far better than a brush, and that the worst form of brush is one with a short handle.

Pennsylvania Bureau of Health for Cities of Second Class.—A bureau of health in the department of public safety in cities of the second class was created by the legislature of Pennsylvania in 1895. The law requires it to remove all things imperiling health; provides a penalty for doing anything tending to endanger health; prohibits placing unsound or offensive matter in street, alley or lot; requires dead animals to be removed within six hours; prohibits rendering or trying out except under certain conditions; provides for abatement of nuisances; prescribes how privies shall be constructed and cleaned; authorizes confiscation of tainted or decayed meats offered for sale, and forbids exposure for sale of decayed or unwholesome vegetables or matter or things; regulates sale of milk; provides that bones, dead animals, etc., shall be hauled in tightly covered wagons, which must not stand on any public street longer than fifteen minutes. The officers of the bureau of health are to carry out these provisions. When the bureau of health shall have reason to believe from the report in writing of any reputable physician practicing in the city that any person therein is afflicted with any contagious disease dangerous to the community it may forbid and prevent all communication with the infected house or family, except by means of physicians, nurses or messengers to convey the necessary advice, medicines and

provisions to the afflicted person or persons, and exercise all such other powers as the circumstances of the case shall require, and as shall in the judgment of the bureau be most conducive to the public good, with the least private injury. The physician of the bureau is, among other things, to keep a supply of vaccine virus, and see that all persons, so far as possible, are properly vaccinated, and to report to the bureau all cases in which any sick person has not been properly cared for. Variola or varioloid is to be placarded as "smallpox," and diphtheritic or membranous croup as "diphtheria." All persons refusing or neglecting to obey an order of the bureau to be vaccinated shall be liable to a fine of from \$5 to \$25. A register of marriages, births and deaths is to be kept, also of physicians, midwives, undertakers and superintendents or sextons of cemeteries. Certificates of death are to be made by attending physician, and also by coroner when the case comes under his notice. A permit to remove a corpse for any purpose must be obtained. Physicians and midwives must keep record of and report births.

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Connecticut: Middletown, February 11, 1 case.
Louisiana: New Orleans, February 1 to 8, 9 cases.
Michigan: Detroit, February 8 to 15, 4 cases, 1 death; Saginaw, Riga Township, February 1 to 8, smallpox reported present.
Tennessee: Fayette County, January 1 to 31, 1 case; Memphis, January 1 to 31, 21 cases, February 8 to 15, 1 case; Obion County, January 1 to 31, 2 cases; Shelby County, January 1 to 31, 35 cases.

SMALLPOX—FOREIGN.

Corunna, January 4 to 18, 3 deaths.
Guayaquil, December 28 to January 31, 18 deaths.
Montevideo, December 21 to 28, 5 cases.
Naples, December 26 to January 31, 68 cases, 45 deaths.
Odessa, January 18 to February 1, 3 cases, 3 deaths.
Pernambuco, November 1 to 15, 87 cases, 28 deaths.
Prague, December 28 to January 4, 22 cases.
Rio de Janeiro, January 11 to 18, 32 deaths.
Trieste, December 29 to 31, 3 cases.
Warsaw, January 18 to 25, 1 death.

CHOLERA—FOREIGN.

Calcutta, December 28 to January 11, 77 deaths.
Bombay, January 14 to 21, 2 deaths.

YELLOW FEVER—FOREIGN.

Pernambuco, November 1 to 15, 8 cases, 4 deaths.
Rio de Janeiro, January 11 to 18, 137 deaths.

ASSOCIATION NEWS.

Section on Neurology and Medical Jurisprudence—Announcement.

—The work of the Section on Neurology and Medical Jurisprudence at the coming meeting of the AMERICAN MEDICAL ASSOCIATION at Atlanta, promises to be of unusual interest. The desire has been quite generally expressed to have discussions upon the following topics:

The Etiology of Insanity.

Expert Medical Testimony in Disputed Mental Cases.

Medical Aspects of Crime.

It is believed that these topics have a special medical interest at this time, and papers dealing with any phase of these subjects will be very welcome. An urgent invitation is extended to all members, whether they are expecting to be in attendance or not, to present papers and records of cases that have a bearing upon the topics mentioned, or upon any other Neurological or Medico Legal subject.

Any persons who expect to contribute papers or reports to this Section will greatly facilitate the business of the Section by writing at once to the Chairman,

T. D. CROTHERS, M.D., Hartford, Conn.
or to the Secretary,

W. J. HERDMAN, M.D., Ann Arbor, Mich.

SOCIETY NEWS.

Sacramento Society for Medical Improvement.—At a regular meeting of the Sacramento Society for Medical Improvement, held Jan. 21, 1896, the following preamble and resolutions were adopted, and copies ordered sent to the medical journals and to medical societies in general, in order to obtain concerted action on the part of the profession:

WHEREAS, The New York Life Insurance Company and the Equitable Life Assurance Society have recently adopted a graded scale of fees for medical examinations, the practical effect of which will be a reduction of the Medical Examiner's income from these sources by about 40 per cent.; and whereas, these companies, claiming to be amongst the largest and strongest in the world, have, hitherto, in common with all other first-class "old line" life insurance companies, paid a uniform fee of \$5 for medical examinations, insisting that the same care be used in examining applicants for small as for large policies; and whereas, under the proposed schedule, no reduction is made in the amount of work performed or in the degree of responsibility exacted: therefore be it

Resolved, That we, as physicians, recognize that all life insurance is based on mortality tables and on the probable life expectancy of the assured, in striving at which the Medical Examiner is the most important factor, and that in the past he has been the most valuable as well as the most essential feature in the establishment of life insurance companies.

Resolved, That we can not recognize, as a principle governing our remuneration for exactly similar services, the amount of premium paid by the applicant, or the profit derived by the company from any individual risk.

Resolved, That such methods, having no foundation in reason or justice, are contrary to all business principles, and must inevitably lead to a lower standard of examinations with correspondingly disastrous results.

Resolved, That the Sacramento Society for Medical Improvement protests against methods that are unfair, irrational, and indefensible, and on behalf of its members, pledges them to absolutely decline to examine applicants for life insurance for any "old line" company, for any fee less than \$5, for each and every examination made.

Resolved, That copies of these resolutions be transmitted to every medical society in California, to all State medical societies, and to the AMERICAN MEDICAL ASSOCIATION, requesting that concerted action be taken in the premises.

THOS. W. HUNTINGTON, Chairman.

W. J. HANNA,

JAMES H. PARKINSON.

The Society believes that success can only be attained through agitation and organized opposition, so that this movement, now confined to two life insurance organizations, may not be adopted by all the "old line" life companies. In forwarding these resolutions, the Society asks you to give the matter the widest publicity, and to, as far as possible, procure similar action on the part of medical societies in your vicinity. J. A. NELSON,

J. H. PARKINSON,
Committee.

Sacramento, Cal., Jan. 25, 1896.

Michigan State Medical Society Committee on Organization.—The following circular letter has been addressed to all State medical societies:

GRAND RAPIDS, MICH., Feb. 4, 1896.

Dear Sir:—At the last meeting of the Michigan State Medical Society a committee (of which I am Secretary) was appointed to consider means relative to promoting more complete or systematic organization of the medical profession throughout the country. In accordance with the request of the committee, I ask you to read carefully the enclosed "Address," and to present the subject, by means of the "Synopsis," to your State Society. Our committee earnestly desires that some concert of action may be had in the matter, and to that end takes the liberty of urging you to use all proper means to have a committee appointed, whose duty it shall be to confer, by letter or in person, with similar committees from other State societies, for the purpose of formulating some plan that may be presented for adoption by the State societies next year. Please let me hear from you at your earliest convenience.

Very respectfully, R. J. KIRKLAND.

1. Every local society, in good standing, shall be a part of the State Society, and under its government.

2. Every State Society shall be part of the National Society.

3. No local society shall be represented in the National organization except through its State Society.

4. A man joining his local society becomes, by that one act, a member of the State and National societies, and can join such societies in no other way. In this way the local society would guard the avenues of entrance.

5. To the annual dues demanded by and payable to the local society, would be added \$3 for the State, and \$5 for the National organization, and would entitle the member to the transactions of both.

6. The degree of "Fellow of the American Medical Association" should be created, and every man qualified to join his local society would be entitled to bear this degree.

7. In the National Society should be formed an Executive Board (from the Presidents of the State societies, or otherwise) which should, among other duties, exercise supervision over the various State societies. And in the State Society a similar board which should exercise a similar jurisdiction over the local societies.

According to this plan a man can join the State and National societies only by being accepted by the local society, where he is known. Thus fewer unworthy men would gain entrance to our National Society. By the payment of \$10 and signing such constitution as may be required, the member would be entitled to the transactions of both his State Society and the National organization, and to write himself "Fellow of the American Medical Association."

The Wayne County (Mich.) Medical Society at its regular meeting, Thursday evening, January 30, met in the Cadillac Hotel, where Frank T. Lodge, M.A., Professor of Medical Jurisprudence of the Michigan College of Medicine and Surgery, read a very interesting paper on, "Insanity, its Relation to Crimes, Contracts and Wills." Insanity was defined in its various phases, and Mr. Lodge showed how the law differed from medicine in the application of the term insanity, and how it addressed itself to the mind and not to the body; that almost anyone was able to make a will, even if they were not able to make a contract. In making a contract it required the application of two minds; there was force against force. In the making of wills this is not the case. If it can be shown that the desire of the person's life points to the manner of his making his will, the court will sustain the will, and as a result comparatively few wills are broken. Upon the other hand, if the lines were too tightly drawn, few people would be permitted to make wills and have them stand; as when old age came on, peculiarities would be manifested, and when sickness invaded the body, the patient would oftentimes be unconscious of his surroundings. The object of judges in constructing wills is to ascertain the testator's real intentions, and if these correspond with his individuality in life, the will would stand. Every court in constructing a contract, first endeavors to ascertain when, and upon what subjects the minds of the contracting parties met; the object of a jury in a criminal court is to ascertain, whether the accused had the evil intention of committing the crime with which he is charged. The object of equity and elastic rules of chancery procedure is to overturn the rigid requirements of the law, to prove the fraud which misled the party and enslaved his mind. It can readily be seen how important in legal jurisprudence is this subject of insanity. The degree of mental capacity that is required of a man differs with the differing relations, and it is on account of these differences that so much uncertainty has arisen in the administration of the law. The degree of insanity is an important factor in fixing criminal responsibility. The mere fact that a person is insane does not relieve him from criminal responsibility. The insanity must have been such as to prevent the accused from distinguishing between right and wrong in a particular act. As a general rule insane persons are incapable of entering into valid contracts. A person who is so insane as to be incapable of entering into a valid contract concerning property can not enter into a valid contract of marriage. Mere weakness of understanding does not invalidate a marriage.

The paper was discussed by Drs. Kirker, Jenks, Inglis, Scurr, ex-Prosecuting Attorney S.W. Burroughs, and Judges Donovan and Chapin.

The Detroit Medical and Library Association at its regular meeting, Monday, January 27, heard a paper by Dr. James Sampson, of Windsor, Ont., entitled, "The Treatment of Renal Calculi." Before reading his paper, the doctor showed plans for a unique, modern hospital, one that could be erected in the down town parts of any city without endangering the surrounding inhabitants.

MISCELLANY.

Virchow Decorated. The decoration of Commander of the Legion of Honor has been conferred upon Virchow by the President of the French Republic.

Pennsylvania New Pure Food Laws. The Legislature of Pennsylvania passed laws in 1895 to provide against the adulteration of food and apple products, and another to prohibit the adulteration of milk by the addition of so-called preservatives.

Instruction for the Laity. The Woman's Union of France has opened a course of free, public, evening lectures on the principles of hygiene and the care of the sick and injured in the family, on the street and on the battlefield, in fourteen different precincts of Paris.

German Congress of Internal Medicine. Our German exchanges announce that the XIV. Congress of Internal Medicine will be held this year at Wiesbaden, April 8 to 11, with an exhibit of medical and surgical appliances in connection. The list of speakers contains some noted names. We notice one American on the list, Einhorn of New York.

Correction.—In the article by Dr. Christison on the "Normal Mind," printed in last week's issue, there was an omission in the plate p. 313 whereby the arrows leading from "fear" and "grief" to "anxiety" were omitted. If those interested will kindly draw the lines at the points indicated, the plate will more clearly show the author's intention.

The War in Cuba. The scientific societies of Havana have suspended their meetings for the present, although their publications appear as usual. The anomalous and threatening conditions that prevail throughout the entire island are driving so many people away from the country that the present and future offer but a gloomy prospect to professional men.

Fecal Micro-organisms. The Biological Society of Paris has been experimenting to determine the number of microorganisms expelled from the body under the influence of a purgative. A healthy subject who evacuated twelve billions on an average during the day, passed four hundred and eleven billions under the influence of a purgative which acted the same day. Succeeding days averaged only half a billion.

The Queen of Portugal. The *Coimbra Medica* of January 10, denies the statement that has been going the rounds of the press to the effect that the Queen of Portugal has been studying medicine and lately received a diploma to practice. The report was probably based on the Queen's interest in various medical institutions, such as the Policlinic, the Diphtheria Serum Service, etc., of which she is an influential and appreciative patroness.

Artificial Testicle. Dr. Guelliot, of Reims, had a patient, one of whose testicles had been removed on account of tuberculosis some years before. The other was attacked in the same way, but the patient would not allow the operation unless an artificial testicle was provided in its place. Dr. Guelliot, after castration, introduced into the scrotum a wad of coarse, soft, sterilized silk (Doelere's No. 4), and completed the suture as usual. The operation was successful. *Revue Internat. de Méd. et de Chir.*, January 25.

Instantaneous Color Photography Discovered by Dr. Selle, of Brandenburg. According to a cablegram to the New York *Herald*, a reported discovery by Dr. Selle, of Brandenburg, Germany, of a method whereby photographs in colors can be instantaneously obtained, is arousing great interest throughout Europe. Several patents, protecting methods for photographing colors, are already filed in Washington. All these patents, however, represent complex processes, while the great value of Selle's discovery lies in the fact that he obtains the same results from one instantaneous exposure.

Memorial to the late Surgeon Parke.—The editor of *Illustrated Africa* writes that "Henry M. Stanley and Lieutenant Jephson, surviving officer of the expedition for the relief of Emin Pasha, have caused to be placed in the church of Kilmore a memorial brass in affectionate memory of the late Surgeon Parke. He first served in Egypt with distinction, accompanying the Nile expedition for the relief of General Gordon in 1884-1885. This tablet is a tribute to his constant gentleness and care for the sick and suffering, and to the splendid services he rendered alike to Europeans and Africans during the three years' march across Africa."

Transposition of Viscera.—Dr. W. Gilman Thompson, professor at the University Medical College, New York City, recently exhibited a man, several of whose organs are transposed, before his class. This patient's heart, stomach and spleen are on the right side and his liver on the left. His lungs are also transposed. The man is perfectly healthy, is about 23 years old, and is a brakeman regularly employed on the Pennsylvania Railroad. He was ignorant of his own peculiarities until a year ago, when he was placed in a Philadelphia hospital; while there doctors informed him. Since then he has given a large share of his time to advancement of clinical teaching.

The Toxic Properties of Alcoholic Drinks Determined by Injecting Them into Rabbits.—Daremborg publishes the results of his experiments to determine the toxicity of alcoholic drinks, in the *Arch. de Méd. Experimentale* of November, 1895. He announces that the most poisonous of all are the liqueurs, such as absinthe, anisette, etc. The least injurious are the drinks made of the alcohol of commerce with non-toxic bouquets, without the addition of liqueurs or cordials. For the same proportion of alcohol, wines are more toxic than wine brandies, and wine brandies are more toxic than brandies made from a good quality of alcohol. Red wines are generally more toxic than white wines. Adulterated and spoiled wines are exceedingly toxic. *Revue Internat. de Méd. et de Chir.*, January 25.

Insane Prisoner to be Removed to Asylum.—Provision was made by the legislature of Pennsylvania in 1895 for the more immediate relief, care and support of indigent insane persons committed on criminal charges less than felony. It is to the effect that upon such commitment when any two physicians of at least five years practice shall certify to his insanity, it shall be the duty of the county commissioners, with the approval of the court of quarter sessions of the county, or one of the judges thereof within fifteen days after such examination, certification and approval, at the expense of the county, to remove such indigent insane person to the proper hospital for the insane, there to be maintained at the expense of such county as indigent insane persons are now kept and supported, until the proper legal settlement of such indigent insane person can be ascertained and determined.

Primary Myoma of the Heart. In the *Centralblatt f. Allg. Pathologie und Pathologische Anat.* for January 18, Dr. Gusti, of Hanburg, described an instance of this rare form of neoplasm occurring in a man, 31 years of age, who died with the clinical symptoms of dilatation of the heart due apparently to a muscular insufficiency because changes in the valves were not demonstrable by physical examination. The post-mortem examination showed two large nodular tumors in the wall of the left auricle, one as large as an apple, the other the size of a walnut, composed of long, narrow spindle-shaped cells, with rod-like nuclei arranged in parallel or interlacing bundles without any intercellular substance. The tumors sprang from the auricular walls and there were no tumors in any other parts of the body. The clinical symptoms are explained as due to the encroachment on the size of the cavity of the auricle. The impossibility to make a clinical diagnosis in cases of heart tumors has often been remarked and in this case another illustration of this fact is brought forward.

Dying Declarations Evidence of Abortion in Pennsylvania.—A law was passed in Pennsylvania in 1895 to the effect that the ante-mortem statements of any woman, who shall die in consequence of any criminal acts producing or intended to produce a miscarriage of such woman, as to the causes of her injuries, shall be competent evidence on the trial of any person charged with the commission of such injuries, with like effect and under like limitations as apply to dying declarations in prosecutions for felonious homicide; provided, however, that before such statement shall be submitted to the jury as evidence the commonwealth shall, by competent and satisfactory evidence, prove that such woman was of sound mind at the time such ante-mortem statements were made: and provided further, that no conviction shall be had upon the uncorroborated declarations of such woman.

Cultures of Pneumococci in Defibrinated Blood.—Experiments were made with liquid defibrinated blood and also with dried. In the former the pneumococci retained their vitality, their continuous growth and their virulence to a remarkable extent. The color of the blood changed, first resembling dregs of urine and then the color of prune juice. In solidified defibrinated blood, the pneumococci did not grow on the surface, but penetrated into the substance, where they flourished luxuriantly. They retained their vitality and virulence for a long while, but with less intensity than in the liquid form. The blood changed in color also, turning first green and then chamois yellow. An important fact noted is that all other organisms except the streptococci vegetate on the surface in solidified defibrinated blood, and do not alter the color. The above report was read at the meeting of the Paris Société de Biologie, January 11, and the opinion was universal that in this material we have a valuable culture medium for the differentiation of the pneumococcus.—*Gaz. Méd. de Paris*, January 25.

Prolific Canadian Half-Breed Family.—A letter to the Philadelphia *Telegraph*, from northern Vermont, refers to a Canadian half-breed with a remarkable family record. His name is Macomber, and he is the son of a French Canadian: he visits northern New York and Vermont selling snowshoes, baskets and moccasins. "The tribe to which he belongs has a reservation twelve miles square. The tribe is descended from the Five Nations. The reservation is known as Caughnawaga. Macomber's grandfather died last week, aged 103, leaving considerable wealth. He had married three times, the first two wives being dead. His first wife bore him six children, the second fifteen and the third the same number. His grandchildren, great-grandchildren, and great-great-grandchildren number over 1,000. Of thirty-six children twenty-eight are living, as are most of the grandchildren, great-grandchildren and the great-great-grandchildren. The tribe claims a portion of Vermont known as the Missisquoi Valley. Chiefs and great men of the Five Nations have appeared before every session of the Legislature for half a century demanding remuneration."

The Congress of American Physicians and Surgeons.—A meeting of the Executive Committee of the Congress of American Physicians and Surgeons was held in New York, Nov. 23, 1895. At this meeting the following officers were elected: President of the Congress, Dr. Wm. H. Welch, of Baltimore; Secretary of the Congress, Dr. Wm. C. Carmalt, of New Haven; Treasurer of the Congress, Dr. Newton M. Shaffer, of New York; Chairman of the Executive Committee, Dr. Landon Carter Gray, of New York; Secretary of the Executive Committee, Dr. Wm. K. Simpson, of New York. The next meeting of the Congress will be held in Washington in May, 1897.

It will be observed that the officers elected are all able and worthy members of the medical profession, but they are all confined to Baltimore, New Haven and New York, while "the sunny south," "the great northwest," and "the land of the

setting sun," saying nothing of the Mississippi Valley, have received no recognition. In fact, the number of square miles included in these appointments, and even the place of meeting would hardly be lost if it should happen to fall out of any of the great western States, and yet this congress has the audacity to call itself the American Congress of Physicians and Surgeons, while in reality it is a congress of a selected few, who have elected all their officers from members who live on the borders of the Atlantic between New Haven and Baltimore. Why not give it its right name? Why ignore the west, the south, the central States, and "the great northwest," and yet call it the Congress of American Physicians and Surgeons, when the facts are that the great masses of the surgeons and the physicians of America who should be members of this congress have been simply ignored? Much better call it by its right name and christen it the Eastern Congress of Physicians and Surgeons.—*Columbus Medical Journal*.

The Medical Journal is the True Post-Graduate Instructor.—The *Archives of Pediatrics* for February contains the following remarks regarding modern medical journalism. They are a part of an unsigned editorial that is, as we believe, from the incisive pen of Dr. Floyd M. Crandall, and they are a part of a series of editorials on the building up of a complete professional character. He says: "Three avenues are open to the physician by which he may keep abreast of the times—books, medical journals and post-graduate schools. The last of these are accessible to but few, and present instruction adapted only to certain cases. The last editions of standard medical books are indispensable to the true student. In the text-book and monograph he finds the various subjects of medical interest reviewed systematically and discussed in all their details. In the medical journal, however, he finds the record of medical progress as he can find it in no other place. The journal with its various departments admits of all classes of medical literature, and contains many practical and important articles which would not be adapted to the more pretentious and dignified bound volume. The well-arranged journal covers the whole field of medical writing, from the scientific original article to the clinical report, which not infrequently furnishes a key to some puzzling case. Such assistance in a single case often proves of a value not to be estimated in dollars and cents. Nearly all the best papers that appear in medical journals are first read in societies. The discussions which they elicit are frequently of even more practical value than the papers themselves. Society reports are justly regarded, therefore, as of very great value to the practitioner. A department of book reviews when conscientiously conducted is also a factor of value to the medical man. The average doctor is limited in the number of books he is able to purchase. A discriminating review, which does not fear to criticise, but does not criticise for the mere sake of criticising, enables him to judge both of the scope of a book and its probable value to him. He is thus able to place in his library those books from which he will derive the most good in his own particular class of practice."

Surgeon-General Sternberg's Defense of the Pasteurian Treatment of Hydrophobia.—According to *Science*, February 7, at a joint meeting of the scientific societies of Washington, held Jan. 14, 1896, a series of memorial addresses was presented, and of these a triad was devoted to men whose names are immortal in the annals of physiologic medicine. Those three are Pasteur for France, Helmholtz for Germany, and Huxley for England. The address regarding Pasteur is by Dr. George M. Sternberg, and presents with characteristic thoroughness the biologic value of the French scientist's work. The following is the view taken by Dr. Sternberg, of the remedial value of the Pasteurian treatment of hydrophobia:

"There has been and is still a considerable amount of scepticism among members of the medical profession, and others, as to the practical value of Pasteur's inoculations for the preven-

tion of hyrophobia: and some physicians have even contended that the disease known by this name is not the result of infection from the bite of a rabid animal, but is a nervous affection due to fear. The time at my disposal will not permit me to present for your consideration the experimental and clinical evidence upon which I base the assertion that nothing in the domain of science is more thoroughly demonstrated than the fact that there is a specific infectious disease known to us as rabies, or hydrophobia, which may be communicated to man, or from one animal to another, by the bite of a rabid animal; and that Pasteur's inoculations prevent the development of the disease in animals which have been infected by the bite of a rabid animal or by inoculations with infectious material from the central nervous system. This being the case, it is evident that there is a scientific basis for Pasteur's method of prophylaxis as applied to man, and his published statistics give ample evidence of the success of the method as carried out at the Pasteur Institute in Paris and elsewhere. Great as have been the practical results which have already followed Pasteur's brilliant discoveries, there is reason to believe that in the future still more will be accomplished, especially in combatting the infectious diseases of man. Having pointed out the way, a multitude of earnest investigators in various parts of the world are now engaged in laboratory researches relating to the cause, prevention and cure of infectious diseases. Already, in the treatment of diphtheria and of tetanus with blood serum obtained from immune animals, results have been obtained of the highest importance, and it seems probable that in the near future other infectious diseases will be cured by a specific treatment based upon scientific information obtained by those who have been following in the pathway marked out by Pasteur, the illustrious pioneer in this line of research."

Practical Notes.

Cortex Monesiae as an Expectorant.—Rosanow, of Moscow, recommends this drug as an efficient cough medicine in cases where ipecac. and other remedies produce stomach irregularities. He prescribes it in the following formula:

R Ext. aquos. cort. monesiae c.c. 2 to 4
Aq. destill. c.c. 150
Syr. simpl. c.c. 30

Misce. A tablespoonful every two hours.—*Therapeutische Wochenschrift*, January 12.

Scopolamin as a Hypnotic for the Insane.—Experiments have been made in Russia with the bromohydrate of scopolamin, which show that it is an efficient hypnotic for the insane. Administered hypodermically in doses varying from one-fifth to one mgr. it produces sleep from three to six hours, and the calming effect lasted after waking. The chronic insane, maniacs and victims of hallucinations were benefited, but it had no effect upon delirium tremens, except to weaken the patient.—*Semaine Médicale*, January 8.

Action of Strychnin in Alcoholism.—Kroutowski describes in *Wratsh*, October, 1895, the action of strychnin on fifty victims of alcohol, presenting various pathologic manifestations. He does not consider its effects durable, and believes it is only beneficial during an acute alcoholic attack, or possibly in forestalling it. But it is not, as some have asserted, a specific for alcoholism: patients apparently cured with it relapse into their old habits at the first opportunity that offers. —*Nouveaux Remèdes*, January 24.

To Remove Disagreeable Taste of Cod-Liver Oil. Add to 100 grams of oil (Duquesnil's preferred) 1 gram essence of eucalyptus. Pavesi's process is to take 400 grams oil, 28 grams roasted and ground coffee, and 10 grams pulverized animal black. Heat this combination to 60 degrees C. in a water bath for fifteen minutes, in a tightly closed receptacle. Let it stand two or three days, shaking it up occasionally, and then filter. This results in a limpid, amber oil with the perfume and taste of coffee. —*Gaz. Médicale de Liège*, January 30.

A New Laryngeal Dilator for Chronic Stenosis. Pfffermann and Bors exhibited a new appliance for this purpose at the last meeting of the Royal Imperial Medical Association of Vienna, which can be introduced without the least pain or inconvenience in the form of a very slender tube. Once in place it can be dilated to the required size with gentle equable pressure on

the sides of the organ. Prof. Weinlechner has used it in hospital treatment with fine results, curing permanently many cases of chronic constriction of the larynx produced by diphtheria, etc., and afforded relief in all.—*Wiener klin. Rundschau*, January 26.

Cinchonidin in Malaria.—The *Therapeutische Wochenschrift* of January 12 gives the following formula for internal use:

R Cinchonidin sulph. 1.00
Acid. tartar. 0.75
Mixt. gummos. 120.00

Misce. Take in the course of the day.

For subcutaneous injections the formula is:

R Cinchonidin sulph. 1.00
Acid tartar. 0.80
Aq. distill. 3.00

Misce. Each c.c. of this solution contains 0.25 of cinchonidin.

A daily dose of 1 gram cinchonidin by the mouth is usually sufficient, but 1.20 or 1.50 can be taken without detriment.

Extra-uterine Pregnancy with Rupture of Sac.—At the December meeting of the St. Petersburg Med. Society, Rymschev described six cases of this kind in which laparotomy was imperative on account of the excessive anemia and scarcely perceptible pulse, owing to the blood flowing into the abdominal cavity. Judging from these and similar cases, he has noted that the abdomen should be opened at once. Even when the hemorrhage stops spontaneously, it is impossible for this mass of blood to be reabsorbed. The Surgical Society of Paris also devoted their last meeting to this subject, and the majority advocated laparotomy in all cases except where an opening through the posterior wall of the vagina is indicated.—*Revue Internat. de M. et de C.*, January 25, and *Progrès Méd.*, January 25.

The Chaput and Murphy Button Compared.—Chaput claims the following advantages for his invention already mentioned in this JOURNAL: 1. The technique is more rapid, since only one suture is required instead of two. 2. My largest button has a smaller circumference than Murphy's smallest, with a larger opening than Murphy's largest. 3. My button does not sphacelate the intestine like Murphy's, and is thus less dangerous. 4. My button can always be inserted in good order, no matter how thick the walls of the stomach or intestine may be, which we know is not the case with the Murphy. 5. While Murphy's button can not be detached, a sound will easily detach mine. 6. My button is very simple, with no delicate nor complicated mechanism, and yet imitations of it can not be made so readily as of the Murphy button.—*Gaz. Méd. de Liège*, January 30.

Castration for Hypertrophy of the Prostate.—The address delivered by Prof. Englisch on this subject and reported elsewhere in this JOURNAL was accompanied by a practical illustration of the effects of this operation. A patient appeared in Prof. Albert's clinic suffering from complete retention of the urine, with the prostate distinctly palpable, complicated with epididymitis and other troubles which indicated castration as the only means of relief. The operation seemed to be a failure at first, as no relief was obtained from it until the fifth week. At that time the urine began to be discharged spontaneously and gradually the prostate decreased in size, resulting in a perfectly successful case, important on account of the way in which the castration produced the desired result in accordance with the latest theories in regard to its modus operandi.—*Wiener klin. Rundschau*, January 26.

Electrolysis in the Treatment of the Nasal Canal.—The *Province Médicale* of January 25, brings us a careful study of this subject, based on the personal experiences of the writer, who states that the failure of this method with other organs, has blinded us to its remarkable advantages in the treatment of the nasal canal, far surpassing those obtained with catheters and injections. It is of the greatest benefit in treating the lachrymal

ducts, much simpler and easier than Bowman's method. One treatment is as effective as a course with the catheter, and the only drawback is the possibility of cicatricial formations, which is still an undecided question.

Antipyrin as an Anesthetic for the Bladder.—Antipyrin is as prompt and certain as cocaine for this purpose, and its use is absolutely free from danger. Pousson writes to the *Journal de Méd. de Bordeaux* that he uses a 2 per cent. solution, although it might be as strong as 4 per cent. without danger. After having injected 50 to 60 grams of this solution, then allowing an interval of five minutes, and injecting again the same quantity, the patient evacuates it alone or with the assistance of a catheter, and the bladder is ready for the introduction of an instrument. He sometimes makes a third injection in order to prolong the anesthesia. If the bladder is sensitive a smaller quantity of a 4 per cent. solution is preferable.

Hooks instead of Sewing for Support of Wound Edges.—Sewing a wound is not always practicable for various reasons, and in such cases the platinum wire hooks and strips of plaster shown in the cut, prove an efficient method. A strip of gauze or rubber should be laid along the plaster edge on the side toward the wound, so that none of the glue can pass into the wound. The plaster should be double, and encircle the entire limb if

possible, leaving a broad space for the wound, to secure asepsis. The wire should be sterilized and bent to fit the limb. *Centraltbl., für Chir.*, January 18.

It will readily occur to most surgeons, that this device, as a support, will prove a valuable resource in cases where early removal of stitches is desirable, and yet there is danger of gaping, and perhaps reopening or infection of the wound.

Oxygenated Water in Hemostasis.—Petit addressed the *Soc. Obst. et Gyn.*, December 12, on the use of oxygenated water in hemostasis. It possesses the three-fold property of promoting the precipitation of fibrin, of stimulating inert fibers, with very little, if any, injury to the tissues. In treating an intra-uterine hemorrhage caused by a fungous metritis or fibroma, if a cotton wad dipped in oxygenated water is introduced suddenly into the organ, froth pours out of the orifice, the organ contracts at once and the hemorrhage is immediately arrested. There is no pain, and no injury to the tissues, while the hemostasis produced persists long enough for an anemic patient to recover strength sufficient to support a more radical intervention if necessary.—*Rev. Internat. de M. et de C.*, January 25.

Fixation of the Liver in Hepatoptosis.—There are so few cases of this kind on record that we quote the following from the publication of the *Moscow Société de Chir.*, October, 1895: A woman of 50 was injured in an accident and her liver displaced. Jaundice, severe pains, impossibility to sit down, distress in

walking and inability to sleep on the left side indicated wandering liver and immediate treatment of some kind. Hepatopexis offered the only means of relief. The organ was found perfectly sound and was fastened with two strong silk threads. The first passed entirely through the liver and back again, with the same needle 4 c. distant, and the thread was firmly fastened in the cartilage of the ninth rib. The second thread also passed entirely through the liver at right angles to the first and the two ends were fastened just above the ninth rib. The surface of the liver was then scratched lightly with the point of the needle to ensure secondary adherence to the diaphragm. At first the rib was dragged down, but this soon righted itself, all pains ceased, and a year later the liver was in the same position and none of the old symptoms had shown themselves except an occasional icteric eruption.—*Prov. Méd.*, January 25.

Detroit Notes.

IN HIS PAPER upon "The Effect of Heart Strain on the Tricuspid Valves," read before the Detroit Medical and Library Association Monday, January 13, Dr. W. R. Chittick brought forward the importance of the subject, at the same time referring to the fact that the text-books have very little to say upon the subject. Much has been written and said upon lesions of the valves of the left side of the heart, but little about those upon the right side of the heart, although the latter are of almost equal importance with the former, though much rarer. In many cases tricuspid follow mitral lesions. If the venous circulation is interfered with by disease, we usually have the right heart correspondingly affected. The doctor went on further to explain what he meant by heart strain, not confining himself to the strain which the heart suffers in excessive athletic exercises, but including also strain occurring in pathologic conditions. In soldiers on forced marches and hunters following their hard mode of life, incompetency of the tricuspid valve may suddenly develop. From such cases we have gained most of our knowledge of these lesions. The doctor then cites several such cases in which he shows how prolonged and excessive work is immediately followed by the suddenly developed tricuspid lesion. Excessive stimulation, as in drinkers, may also be an etiologic factor. This lesion is often followed by mitral incompetency, and the former may not be recognized until the latter begins to develop. In pulmonary congestion, due to any disease or pathologic condition of the body, blood may be backed up into the right ventricle, and the tricuspid valves becoming incompetent, be further backed up into the liver. The thinness of the walls of the right ventricle allowing of distension may sometimes save the valves upon that side, and this may account for the lesser frequency. Though great stress has been laid upon venous pulsation in the neck in tricuspid insufficiency, the writer had found this absent in several cases which he had seen. Another diagnostic point he had not always found present, namely, hepatic systolic pulse. The venous engorgement in some cases may further affect the structure of the kidneys, producing uremic symptoms. The paper was discussed by Drs. W. McDonald, E. S. Shirrell, Chas. Douglas and J. Flinterman.

THE WAYNE COUNTY MEDICAL SOCIETY at its regular meeting Thursday, February 13, listened to an interesting paper by Dr. Edward W. Jenks, entitled "One of the Lost Arts of Gynecology."

HEALTH OFFICE REPORT for week ending Feb. 15, 1896: Deaths 93, under 5 years 33; births, male 52, female 40, total 92. Contagious diseases: Diphtheria, last report 7, new cases 6, recovered 4, died none, now sick 9. Scarlet Fever: Last report 20, new cases 4, recovered 11, died one, now sick 12. Smallpox: Last report 2, new cases 4, recovered none, died one, now sick 5.

Washington Notes.

TO TEST THE CONTAGIOUS DISEASE LAW.—A warrant has been issued for the arrest of a Washington physician on the charge of violating the contagious disease law. It is alleged he failed to make a proper report of a case of diphtheria.

A NEW FREE DISPENSARY.—Articles incorporating the South Washington Free Dispensary have been filed with the Recorder of Deeds by Drs. James T. Morgan, D. K. Shute, George Barrie and Henry A. Robbins. The dispensary will be put in operation at once. Dr. Morgan will have charge of the department of diseases of throat, chest, and general medicine; Dr. Chas. L. Allen, nervous diseases; Dr. Barrie, surgery; Dr. Robbins, skin and venereal diseases; Dr. H. D. Fry, diseases of women, and Dr. D. K. Shute, diseases of the eye.

COMMITTEE ON PUBLIC HEALTH.—The committee of the Board of Trade on public health held an important meeting on the 15th instant and have arranged a report for presentation to a public meeting of the Board to be held during the coming week. Sewer extension, water supply and filtration, and prevention of typhoid fever will be fully discussed.

THE POST-GRADUATE SCHOOL OF MEDICINE OF THE DISTRICT.—The act of Congress incorporating the Post-graduate School of Medicine of the District of Columbia, which passed both Houses, was signed by the President on the 7th instant and has consequently become a part of the revised statutes. The school is allowed to hold real and personal property to the amount of \$200,000. The course of teaching has been arranged and the school will be in operation shortly.

A MEDICAL LAW TO BE REPEALED.—The Senate Committee on Military Affairs favorably reported the bill repealing the existing law which requires surgeons and other medical officers of military homes to be persons who have been disabled in the military service of the United States.

A SYSTEMATIC TRADE IN CADAVERS ACCIDENTALLY DISCOVERED. The police are investigating a case of grave robbery. The first known of it was when a report came to headquarters that a box containing two corpses had been left at the Baltimore & Ohio station last week by three colored men, who put it on the freight platform. One of the men said the box was to be sent through, expressage to be collected at the other end. Later, when the men at the station took up the box they found that there were two addresses upon it. One was "Angus McLane, 223 Pelham Street, Detroit, Mich." In another place was the address of a Baltimore firm. It is supposed one of these was inadvertently left on, but the trainmen were in doubt as to the proper destination of the parcel. To get some clue of the destination the lid was forced off. The men, who supposed that the contents were merchandise, were surprised to discover the bodies of two colored women.

PHYSICIANS ON THE WITNESS STAND. Senate bill 981, relating to the testimony of physicians in the courts of the District of Columbia, was the subject of a report to Congress by the Commissioners. They inclose two reports upon the bill, one from the justices of the supreme court of the District, and the other from the president of the Medical Society of the District. The bill proposes to exempt and prohibit physicians from disclosure in the courts of information obtained in attending a patient in a professional capacity. The judges report against the measure. They say: "The enactment sought by the bill would be a serious obstruction to justice in contests over life insurance, personal injury from negligent or willful act, wills and others in which mental capacity is involved. In such cases facts coming under the observation of the attending physician are generally of first importance, and in cases involving questions of mental capacity the opinion of the physician, based in whole or in part upon communication made to him by the patient, is frequently the most important evidence adduced. These objections are not obviated by placing such evidence within the power of 'the person afflicted, or of his legal representative,' to permit or deny. It is not to be anticipated that such person will ever consent to the examination of a physician whose testimony is expected to be adverse to him, and the other party to the litigation, and the court as well, perhaps with the full knowledge of the situation, would be powerless in such instances to require the truth to be shown." The report of Dr. Bussey, President of the Medical Society, says the bill was drafted by direction of the Medical Society. It is, he says, modeled on the law of the State of New York, and is substantially the same as similar laws in force in twenty States and one Territory of this country, the first of which was enacted by the State of

Oregon in 1872, and the latest in 1887 by the States of Indiana, Wyoming, Montana and Idaho. The report argues at considerable length against the position taken by the judges.

MICROSCOPICAL SOCIETY.—At the regular meeting of the society held on the 11th inst., Hon. A. A. Adey presented the subject of photomicrography.

MEDICAL SOCIETY. At the meeting of the society held on the 12th inst., Dr. S. O. Richey read a paper entitled "Fads and Fashions in Surgery."

THE BILL TO REGULATE the practice of medicine and surgery in the District of Columbia passed the House February 11.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from February 8, 1896, to February 14, 1896.

First Lieut. William W. Quinton, Asst. Surgeon, will be relieved from duty at Ft. Riley, Kan., and ordered to Ft. Logan, Colo., for temporary duty.

Capt. C. N. Berkeley Macauley, Asst. Surgeon, died Feb. 6, 1896, at Ft. Logan, Colo.

Major Joseph B. Girard, Surgeon, will be relieved from duty at the Presidio of San Francisco, Cal., and ordered to Jefferson Bks., Mo., for duty at that post, relieving Major Robert H. White, Surgeon. Major White, upon being relieved, will proceed to Presidio of San Francisco, Cal., for station.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending February 15, 1896.

Surgeon J. M. Steele, detached from the "Independence" and ordered to the "Monadnock."

Change of Address.

Cobb, J. O., from Port Townsend, Wash., to U. S. Marine Hospital, Cincinnati, Ohio.

Davis, W. M., from Chicago, Ill., to Blackfoot, Anderson Co., Texas.

Ferguson, Clara, from Tipton, Iowa, to Dunning, Ill.

Hubbard, Thomas, from 205 Ontario St. to 145 22d St., Toledo, Ohio.

Kelly, E. E., from 1247 Market St. to 803 Sutter St., San Francisco, Cal.

Martin, C. M., from Belding, Mich., to Bellevue, King Co., Wash.

Regensburger, M., from 114 Geary St. to 803 Sutter St., San Francisco, Cal.

Russell, E. David, from Cedar Bluffs to Iowa City, Iowa.

Taylor, W. H., from 329 W. 7th St. to 553 W. 7th St., Cincinnati, Ohio.

ADDRESS.

THOUGHTS ON GENERAL AND CARDIAC THERAPY.

President's Address before the Burlington Clinical Society, Nov. 29, 1895.

BY D. C. HAWLEY, A.B., M.D.,

BURLINGTON, VT.

During the last quarter century remarkable advancement has been made in every department of medicine. While in the realm of therapy, advancement toward scientific accuracy has perhaps hardly been in keeping with the general progress, still modern therapy is becoming one of the more exact branches of medicine. It is not based entirely upon empiricism, as was formerly the case, but is establishing itself upon a basis which may be called scientific or rational. In treating disease empirically, a certain remedy is used because it seems to have been valuable in treating the same disease or conditions. I do not deny, or wish to under-estimate, the value or success of such treatment in many cases, but would emphasize the fact that the method is anything but scientific. A system of scientific medication must be founded upon a knowledge of the natural history of the diseases to be treated, and of the agents to be used. Or more accurately, scientific therapy must be based upon a knowledge of physiology, pathology and materia medica. This implies a knowledge of physiologic effects of drugs, and their action upon healthy states and conditions, and of the indications for treatment, based upon clinical and post-mortem observations of the natural history, that is, the cause, course and results of diseased states and conditions, as well as a knowledge of the physical and chemie characteristics of remedies. I am aware that we are at present unable to base all our therapeutic methods upon this scientific basis. But as our knowledge of pathology and the natural history of disease advances, I believe there will be a corresponding advance in scientific therapeutics. Every physician possessed of the truly scientific spirit and equipped with all the knowledge available along the lines above indicated, will hardly be satisfied with what are known as shot-gun prescriptions, or with happy combinations, but will select his therapeutic agents with an eye to the good of his patient and the honor of his profession.

With a deeper insight into physiology and pathology we shall surely learn more of the value of what may be styled physiologic remedies, and place more reliance on a proper application of air, food, water, rest and exercise. If we recognize our dependence upon the *vis medicatrix nature*, and learn to make a more intelligent use of scientific and of physiologic remedies, we ought certainly, as a natural result, to abandon any allegiance we may have formed with polypharmacy, and also in a great measure with symptomatic therapeutics. To illustrate, let me call

your attention to the symptomatic treatment of typhoid fever by modern antipyretics, and by modern antiseptic remedies. With what enthusiasm has one and another physician lauded the use of antipyrin, phenacetin or acetanilid in reducing the temperature and ameliorating the symptoms in this disease! But to-day we are well awakened to the fallacy of considering hyperpyrexia the principal destructive agent or process, and the coal-tar derivatives are practically abandoned, as being not only useless, but actually dangerous. What is known as intestinal antiseptics is much in vogue at the present time. We are asked to believe that naphthol, salol, zinc sulpho-carbolate, bismuth salicylate, hydrogen dioxid, sulphur, etc., administered at intervals of two to four hours, will disinfect or render aseptic the mucous membrane of the intestinal canal, and destroy the pathogenic micro-organism which is the cause of the disease, or the toxins which are generated thereby. This treatment is supposedly based upon the germ theory of disease. Suffice it to say that thus far none of its advocates has done more than to advance their claims; they have proved nothing. The drug has not been discovered which shortens by a day the course of the disease.

Allow me to call your attention briefly, by way of contrast, and to illustrate the difference between empiric or symptomatic treatment and what I have called scientific treatment, to a remedy, a physiologic remedy, which has established itself firmly in the therapeutics of enlightened medicine the world over. I refer to the Brandt method of balneo-therapy. I take pleasure in quoting the following from an eminent authority¹ as to its effects: "The rationale of the bath is so simple that it appeals to our best judgment at once. We have an overwhelming of the nerve centers by the products of infection. The shock and the subsequent stimulus to the cutaneous surfaces are conveyed to the nerve centers, and thence reflected to the heart, lungs and other organs. Observations at the bedside at once renders these effects patent. The first effect is a refreshment, an enlivenment of the cerebrum. The eyes are opened; the face loses its apathetic stare; consciousness returns after one or more baths; the inspiration is deepened; expectoration is facilitated; the widening of the peripheral vessels and the stimulation of their coats relieve the heart; blood pressure is increased and the laboring organ becomes as quiet as does a sea-tossed ship in the hands of a skilled mariner. The secreting glands are aroused to activity. Moreover, the temperature is reduced, not so violently as by medicinal agents, but more definitely, more in accord with normal tendencies. . . . It has been recently shown by Thayer, in the Johns Hopkins laboratory, that the leucocytes are more than doubled after a Brandt bath. On the other hand, the destructive

¹ Simon Baruch.

effect of medicinal antipyretics on the leucocytes, their inhibition of excretion of products of tissue change and their effect on the heart have been again and again demonstrated." I believe that one of the greatest improvements in our methods of treatment, which may result from what I have styled scientific medication, will be the withholding of remedies of uncertain value, in other words, less medication. I do not say that scientific medication means no medication, but I believe that as our skill in diagnosis increases, our faith in polypharmacy will decrease.

With these remarks on therapy in general, I wish briefly to call your attention to a branch of the subject in which there seems to have been considerable advancement toward scientific precision, viz., cardiac therapy. I venture the statement that there is no department of therapeutics in which knowledge is so exact as in that relating to cardiac disease. Our knowledge of the action of the heart in normal as well as in pathologic conditions, ought to tell us why and under what circumstances a given remedy may be useful, provided we know its physiologic effects. The principal remedies which directly affect the heart and blood vessels are digitalis, strophanthus, strychnia, spartein, convallaria, caffein, glonoin, aconite, veratrum viride, opium, bromids and ergot. Let us briefly review the physiologic action of some of these remedies, when administered in medicinal doses.

Digitalis stimulates the motor ganglia of the heart, increasing the force of the ventricular contractions. By stimulating the inhibitory fibers of the pneumogastric, it lengthens diastole, thereby giving time for the cavities to receive more blood. It also acts upon the vaso-motor ganglia in the medulla, causing contraction of the arterioles and thereby increasing arterial tension. It is a vascular stimulant raising arterial pressure, and steadying the heart by lulling it into long diastoles. Is digitalis a cardiac tonic as well as stimulant? It certainly increases the nutrition of the heart muscle by supplying it liberally with blood. The coronary arteries fill during diastole and when the heart is acting powerfully and steadily under the influence of digitalis, the increased volume of blood swells the aorta, which, in turn by a mighty recoil, fills the coronary arteries and carries food to every part of the heart.

Strychnia stimulates the vaso-motor centers, constricting the capillaries and causing an increase of arterial tension. It also stimulates the vagus, inhibiting cardiac contractions. Thus we see it has a double action in slowing the heart.

Cocain affects the vaso-motor centers and the cardio-motor ganglia, increasing arterial tension and the force of the heart's action.

The action of belladonna is to increase the force and the frequency of the heart's action by stimulating the cardiac ganglia and by paralyzing inhibition. It also raises the blood pressure through capillary contraction, due to vaso-motor stimulation.

Ergot, by stimulating the vaso-motor ganglia, decreases the caliber of the arterioles and produces a marked increase in arterial tension, thereby causing the heart's action to become slower. It also acts on the unstriated muscular fibers in the arterioles, aiding their contraction. All the remedies thus far considered, viz., digitalis, strychnia, cocain, belladonna and ergot may be classed as vaso-constrictors.

Aconite, by lowering the action of the cardio-motor ganglia, lessens the force of the systolic contractions

and by stimulating the vagus, lengthens the interval between the beats. It also dilates the peripheral vessels, probably through vaso-motor depression, thereby lowering blood pressure and slowing the heart.

Veratrum viride depresses the vaso-motor centers, dilating the vessels and reducing vascular tension. By a direct effect upon the heart and its contained ganglia it lessens the force and frequency of its pulsations.

Glonoin increases the energy and rate of the heart's contractions and lowers vascular tension by widening the blood paths. The former is done by directly stimulating the heart, the latter by its action on the muscular coats of the arterioles, and not by depression of the vaso-motor centers. Aconite, veratrum and glonoin may then be classed together as vasodilators, but with this difference in their action, while aconite and veratrum depress the heart's action, glonoin increases it.

Strophanthus slows the heart's action, lengthens diastole and increases the force of the muscular contractions, thereby raising arterial pressure, but does not affect the caliber of the vessels through the vaso-motors.

Convallaria, by direct action on the heart, lessens the frequency and increases the force of systole, thus raising arterial pressure. It does not affect the vaso-motors or the pneumogastric.

Caffein stimulates directly the heart, increasing its contractions in force and frequency. It causes dilatation of the arterioles, not by vaso-motor depression, but by an action upon the intra-vascular nerve ends (Senmola). Large doses affect the vagus, decreasing the number of systolic contractions.

Cactus shortens and increases the energy of systole, raises arterial pressure and shortens the intervals between the beats. Under its use the pulse becomes quicker and stronger.

Spartein primarily increases the pulse rate, and the force of the heart. This increase of the heart's action is soon followed by a decrease of the same. The augmented rate is due to an action of the drug on the heart's muscle or its ganglia, and the decrease to stimulation of the cardio-inhibitory centers. Spartein increases the blood pressure by its action on the heart and by stimulating the central vaso-motor system, and subsequently decreases it by a depressing effect through the same channels.

Thus we see that strophanthus, convallaria and cactus have no appreciable effect on the caliber of the vessels, while the effect of caffein and spartein in this direction is less marked than is that of the drugs we have classed as vaso-constrictors. The effect of opium is to stimulate inhibition, producing a slow and full pulse with increased arterial pressure. Systole and diastole are both lengthened. Bromids lessen the force and frequency of the pulse, as well as arterial tension. It is claimed by Hammond that bromids produce contraction of the arterioles of the brain, thereby causing cerebral anemia. In the study of cardiac therapeutics it is well to bear in mind that the heart is a double pump with normal valvular insufficiency on the right side and with perfectly closing valves on the left side; that the principal resistance to the flow of blood is in the arteries and arterioles, and not in the veins; that the capacity of the veins is double that of the arteries, and that the abdominal vessels when dilated are capable of holding

all the blood in the body. By the use of the vaso-constrictors we increase arterial tension, and as a result send an increased quantity of blood through the coronary arteries, thus improving the nutrition of the heart muscle. In a dilated heart without compensatory hypertrophy, we may, by increasing peripheral resistance and keeping it just within the power of cardiac contractions, bring about hypertrophy of the left ventricle, and thus restore the circulation to a nearly normal condition. This has been proved by Oertel. The effect of the vaso-constrictors may be carried too far, and so narrow the arterioles, as to send the blood so rapidly through the capillaries as to cut off nutrition from the heart. The administration of nitro-glycerin, which has the power of dilating the capillaries, will, however, remedy this over-contraction. The vaso-constrictors increase peripheral resistance and lower the rate of the heart's action. The vaso-dilators, on the other hand, decrease peripheral resistance and lower the rate and the power of cardiac contractions.

Now the question arises, what working conclusions are to be drawn from these considerations? Let us try for a moment to apply the above data to some of the conditions which we daily meet. In mitral stenosis we have at the mitral orifice an obstruction to the free flow of the current of blood from the auricle to the ventricle. The orifice being narrowed, the auricle can not pump the normal quantity of blood through it, in the time allotted, and in an attempt so to do, the heart works at an increased rate. Dilatation of the auricle follows, and there is a stasis of blood on the venous side of the heart while the vascular tension is lowered on the arterial side. What must be done to help that heart? We must increase the power of the ventricular contraction in order to overcome the effect of the dilatation, at the same time that we lengthen diastole, to give the auricle time to empty itself. We must also increase the blood pressure in the arteries for the benefit of the coronary circulation, and must work the blood over from the venous to the arterial circulation. If our findings in the physiologic action of drugs are correct, here is a field for the use of either digitalis, strychnia, strophanthus, spartein, convallaria or ergot, or a combination of two or more of them. In regurgitation at the mitral valves, we have the conditions above noted, with the addition of eccentric hypertrophy of the ventricle. Such a heart may be in great distress, putting in thirty to fifty extra beats per minute, with the veins full and the arteries empty. Systole is weak and diastole too short for the ventricle to fill with blood. The indications are plain: shorten and strengthen systole and lengthen diastole. To do this we must turn to the same remedies mentioned in speaking of mitral stenosis. Here is an opportunity to use the full physiologic effect of digitalis. Having secured that effect, having restored the equilibrium of the circulation it is probably better to combine glonoin with the digitalis, in order to cut out the vaso-constrictor effect of the latter. In some cases a combination of ergot, for its vaso-motor effect, with spartein or strophanthus, will accomplish all that is desired. The other drugs mentioned in connection with these lesions are valuable and play an important rôle in cardiac therapy, but having pointed out the general indications for their use, we will not attempt to do more at the present time. In aortic stenosis, so long as hypertrophy keeps pace with the obstruction

and with the ventricular dilatation, all goes well. But when the compensation is broken, when the obstruction or the dilatation, or both, get ahead of the hypertrophy, then the ventricle is unable to send the full charge of blood through the narrowed aortic opening. At each contraction of the ventricle some blood is left within its cavity, and the blood flowing in from the auricle as usual, causes a surcharge of blood within the ventricle. This condition makes it impossible for the auricle to fully empty itself and here again we have dilatation resulting. Nature at once attempts to compensate by starting a hypertrophy of the left auricle; but this only adds fuel to the flame, for the increased power of the auricular muscle sends more blood into the crippled ventricle, which is already distended to such an extent as to destroy the compensatory balance. The effect upon the circulation is decreased arterial tension, and engorgement of the pulmonary and venous circulation. Now what are the indications? Plainly, to strengthen systole, shorten diastole and increase arterial tension. We certainly must not look to digitalis and its congeners to meet these indications. Cactus, caffein and cocain, from their physiologic effects, may be expected to do much for us, and experience has proven their value in aortic stenosis. In aortic regurgitation we have eccentric hypertrophy of the left ventricle from a reversed current of blood from the aorta. Regurgitation becomes rapid and prevents the perfect filling of the coronary arteries. The hypertrophy so increases blood pressure as to produce endarteritis and finally atheroma. Thus the heart muscle becomes impoverished and dilatation without compensation results. Regurgitation through the aortic orifice takes place during diastole. If we can shorten diastole and strengthen systole, we are certainly doing something toward restoring the circulatory equilibrium. Again our physiologic findings point to cactus, caffein and cocain. We have it on so good authority as that of Dr. Reynold W. Wilcox, of New York, that cactus has proved itself, clinically, to be the remedy, par excellence, in aortic regurgitation. Lesions of the right heart being rare we will pass over their consideration. In cases where there is increased peripheral resistance as in pneumonia in the first stage, chronic disease of kidneys, etc., we find a special field for the use of the vaso-dilators, viz., aconite, veratrum and nitro-glycerin. In the first stage of pneumonia we have engorgement of the blood-vessels of the lung, with increased action of the heart. If we give veratrum, we bring down the heart's action and dilate the blood-vessels throughout the body. We take the blood away from the lung, and we practically bleed the patient into his own vessels. I am well aware of the important rôle played by hygienic, dietetic and mechanical agents in cardiac therapy. However, a consideration of these in detail is entirely without the scope of this paper, in which I have endeavored to call attention to the scientific use of some of those agents, which strictly speaking, must be set down as secondary to a proper regulation of rest, diet and regimen, in the treatment of cardiac disease.

Insufflation as an Aid in Diagnosing Gastric Stenosis.—A severe case of what was supposed to be cicatricial stenosis of the pylorus, was differentiated as constriction through the center of the stomach and treatment indicated by means of insufflation. The *Prov. Med.* of January 11 records the case, with details of effect of insufflation as aids to diagnosis.

ORIGINAL ARTICLES.

A PRELIMINARY REPORT ON THE
ROENTGEN OR X RAYS.

Read at the Meeting of the Chicago Medical Society, Feb. 17, 1896.

BY JAMES BURRY, M.D.

CHICAGO.

Probably no scientific discovery has received wider attention than the promulgation of the use of this ray has elicited.

Prof. William Conrad Roentgen attracted the attention of the world when he succeeded in making photographs of the bones of the human body through the living subject. Earlier experimenters had described photographic activity in cathode rays, and it may be proper to consider some of their work.

In 1879 Prof. William Crookes presented to the Royal Society a paper embodying the results of a series of remarkable experiments on electrical discharges through vacua. Previous to this, experimenters had investigated discharges through rarefied gases, and had observed in a general way the behavior of discharges in comparatively high vacua. Faraday also had speculated on the possibility of an attenuated state of matter in which the behavior of molecules might be expected to be different than in the case of matter in any ordinary form. Such attenuated matter he designated "radiant matter." Crookes, however, was probably the first to conduct an exhaustive investigation on the discharges in very high vacua, and to connect the state of the attenuated gases with Faraday's hypothetical radiant matter.

At ordinary atmospheric pressure an electrical discharge of high tension takes place usually in the form of sparks between the charged terminals, or, under certain conditions, in a practically continuous discharge called a "brush." At a much diminished pressure, say one-thousandth of the atmospheric pressure, the discharge between the terminals becomes continuous and is characterized by a diffuse illumination, the color of which is distinctive of the gas through which the discharge takes place. The discharge is probably in the nature of electric conduction, and the tubes or bulbs prepared to exhibit such discharges are termed Geisler tubes.

At much higher vacua, approximating one-millionth of atmospheric pressure, the character of the discharge in the tube undergoes a marked alteration. The illumination of the path of the discharge is much diminished. A dark space surrounds the negative electrode or cathode in the bulb, the depth of the space being determined by the degree of exhaustion of the bulb, the observed path of the discharge is no longer in a line joining the negative and positive electrodes—the cathode and anode—but appears to be independent of the anode.

Crookes' investigations were conducted principally with discharges of this character, and the highly exhausted bulbs which he used are designated "Crookes' Tubes."

Crookes applied to the rarefied gases or vapors in his tubes the borrowed term "radiant matter." He assumed that within the exhausted tube the matter was attenuated to such an extent that a molecule is free to move through a sensible distance, enormous in comparison with the similar distance at ordinary pressures, without colliding with another molecule. He supposed that the molecules within the tube were

projected from the cathode at a high velocity, moving from the cathode in lines normal to its surface and being stopped only by collision with other molecules, with a screen in the tube, or with the wall of the tube. At a certain distance from the cathode the rapidly moving molecules thrown off from the electrode collide with the reflected molecules; the distance from the cathode at which the greater number of these collisions takes place was considered as being coincident with the limit of the dark space, and the depth of the dark space surrounding the cathode was taken as representing the average free path of the molecules within the tube.

His experiments demonstrated, among others, the following propositions which are of value in considering the cathode or X rays:

Ordinarily radiant matter moves in straight lines; the path of the matter may be deflected by a magnet; the impact of the molecules on a surface exerts a pressure, which is sufficient in some forms of his apparatus to move vane wheels; the impact of the molecules generates heat in any body with which they collide, and excites fluorescence in many substances capable of such action.

A few years ago Dr. Heinrich Hertz discovered that the effect of the bombardment with the Crookes' tube was not limited by the walls of the tube; in other words, that the effects of the bombardment were noticeable outside of the tube. He observed that fluorescence was excited in fluorescent substances outside of an aluminum window in the Crookes' tube which was being bombarded by the molecules projected from the cathode. He suggested that this might be due to an actual projection of the radiant matter through interstices in the walls of the tube, or of the aluminum window.

In 1894 Philip Lenard, a pupil of Hertz, showed that this assumption was untenable, and that the effects observed outside the Crookes' tube might be more reasonably accounted for as due to a vibration of the ether created by the cathode. These vibrations he found to be capable not only of exciting fluorescence, but of precipitating chemie changes in photographic plates. He observed that the "cathode rays," as he called the vibrations, might penetrate to a considerable distance outside of the tube, all substances being to different extents penetrable by the rays.

Within the last three months Professor Roentgen has announced the discovery of a ray proceeding from the excited Crookes' tube characterized by behavior different from that of the cathode rays. He stated that the newly discovered Roentgen, or, as he designated it, the "X" ray, proceeded not from the cathode, but from the point in the wall of the tube upon which the radiant matter in the tube impinged. The point from which these X rays emanated can be shifted by changing the path of the radiant matter with a magnet so as to make the molecules strike on a new point of the tube. The X rays, on the other hand, could not be deflected by a magnet, were not reflected by any body which obstructed them, and were not refracted by any body which was transparent to them. For the most part the law of the X rays, as announced by Roentgen, are quite similar to those announced by Lenard for the cathode rays. Hence there is still some doubt as to whether the X rays are not in fact identical with the previously known cathode rays. However, the announcement of Professor Roentgen's

discovery was accompanied by the statement that the bones were less penetrable to the X rays than the soft tissues, that a photograph or shadow picture might be obtained showing the bones within living bodies. This startling statement gave a prominence and value to his work which obtained for it instant recognition.

The surgical importance of securing outlines of deeply imbedded bones or foreign substances appealed to me strongly. My first experiment was made with a two-cell battery, a one-half inch spark induction coil and an incandescent lamp for a Crookes' tube. This experiment was made on the 4th inst. and was unsuccessful. On the same day, after a liberal use of the telegraph I secured two Crookes' tubes from a house in Philadelphia. The tubes could not be secured

company with Mr. Scribner and Mr. McBerty, my experiments were resumed.

Our first efforts were made with a four-volt primary and a $1\frac{1}{2}$ inch induction coil. The tube was placed immediately above the object to be photographed, with the latter resting on the wooden slide of a holder containing a photographic plate. In this way, with thirty minutes exposures, shadowgraphs were secured. These shadowgraphs gave but dim and indistinct outlines of the bones. Experiments were then made by varying the time of exposure, the distance between the bulb and the plate, the voltage of the primary current and the number of interruptions. After these experiments, which gave but fair shadowgraphs, a lead diaphragm with an aperture of one-half inch in

ROENTGEN PICTURE TAKEN BY DR. BURRY AND CHAS. E. SCRIBNER, FEB. 14, 1896.

either in Boston or New York. One of these tubes is worthless. The other is the one with which all our successful work has been done.

The tube is spherical in shape with four electrodes entering it, one pointed terminal at each end, a disk terminal in one side and a pointed terminal in the other side. All of these electrodes are made of aluminum connected with a platinum wire. As I use it the disk terminal is the negative or cathode and the pointed terminal the anode. From the cathode emanate the rays which travel in straight lines and independently of the anode, producing in this tube a greenish-yellow light.

On Thursday the 6th inst., on invitation of Mr. Scribner, I took the tubes to the experimental laboratory of the Western Electric Company, where, in

diameter was interposed between the bulb and the plate, the distance of the bulb from the plate reduced to eight inches, and longer exposures made. The aperture in the lead diaphragm was placed below and in a line with the fluorescent spot in the bulb. These changes gave improved results. By varying the distance from two to fifteen inches between the bulb and sensitized plate, increasing the aperture in the lead diaphragm, and with the bulb six inches from the plate a perfect shadowgraph of the bones in the hand, wrist and a part of the forearm was obtained.

On Tuesday, the 11 inst, a small buckshot was located in the hand of a painter, between the fourth and fifth metacarpal bones near their carpal ends by means of the shadowgraph, and this shot I removed

in Mercy Hospital. This is the first instance in America as far as I can learn, of the removal of a foreign body following its location by such means, and where it could not be located by any other means.

These shadowgraphs show that the soft tissues make some impression on the plate. It does not seem improbable that with a more intimate knowledge of these rays, some way of controlling them, as is the case with all other known rays, will be found. It may then appear that the varying changes in disease and health of the soft tissues, as shown by the shadowgraph, will become known and in this way a cirrhotic liver may be differentiated from a normal one, or pulmonary tissue in pneumonitis from normal tissue. Certainly, calculi of the kidneys or gall ducts should be easily disclosed.

In the shadowgraph (see illustration) the marrow cavities of the metacarpal bones clearly appear, thus showing that these rays do penetrate bone tissue, making it not improbable that the pathologic changes in bone tissue can be shown as well as foreign bodies of substances impenetrable to these rays that may be deeply imbedded in bone.

I have exposed tuberculosis bacilli to the action of the X rays for two hours but have not had time to make cultures, so I can not make any report as to the germicidal or other action of the rays at this time. The therapeutic uses of this ray, if there are any, must be determined by careful experiment, and speculative thought in this direction is apt to be disappointing. Many uses are suggested to which this ray can be put, and the newspapers are full of experimental researches in this country and abroad. We find that many of the Universities in the East, as well as our own, are making experiments, and various reports have been printed in the papers on the work of these scientists. Out of all this work must proceed some good.

Among the claims are many ludicrous ones, as they appear in the papers. For instance, it is said that at Columbia College the shadow of a bone was projected on the brain of a dog and he immediately became hungry. In another case reported in the paper a New York physician succeeded in getting a good negative of his own brain. Is it pardonable to suppose that the plate was simply "foggy?"

Whatever the future may show, these shadowgraphs prove, at least, that as far as the extremities go, no engraving can portray the bones as well as a good shadowgraph.

Bario-platino-cyanid becomes phosphorescent under these rays. Upon a fluorescent screen of this powder it is perfectly possible to project an instantaneous shadow which would reveal to the surgeon all that a good shadowgraph would show, and it is in some such way as this, it seems to me, that this process will be most used by surgeons. If I am correct in this, two minutes time would give the surgeon a clear idea of the condition of the parts he wishes to investigate, thus doing away with the present great disadvantage of the long exposure necessary to secure a good shadowgraph negative.

Fractures through the shaft of bones are usually easily diagnosed, but those near joints are sometimes difficult to recognize. This difficulty will be easily overcome by means of the Roentgen ray.

Some of the features of this work are remarkable in showing the striking difference between the penetra-

bility shown by bodies to this ray as against the white rays of the sun. For instance, glass which is so easily penetrated by the white rays, is very feebly, if at all, penetrable by the X ray. On the other hand, aluminum is readily penetrated.

One medical use may be in convincing patients who believe that they suffer from some organic disease, when none is present, that they are mistaken by showing them a shadow of the organ that they fear is affected.

Beyond Roentgen's application of his ray, and his statement that the ray can not be deflected by a magnet so far no advance has been made on the work of Prof. Philip Lenard as shown by his papers published in 1894.

THE PROPOSED INTERNATIONAL MEDICAL INSIGNIA.

BY COL. R. FRENCH STONE.

SURGEON GENERAL INDIANA NATIONAL GUARD.
INDIANAPOLIS, IND.

Since the recent publication of various articles with reference to the above subject have appeared in the leading medical journals of this country, and especially of those from the editorial pens of the *Boston Medical and Surgical Journal*, the *Journal of the Army and Navy* and of the AMERICAN MEDICAL ASSOCIATION, much interest has been excited and great unanimity of opinion expressed concerning the symbolism and esthetics of our profession. As one phase of the development of this question it may be stated that Col. C. H. Alden, Assistant Surgeon General of the U. S. Army, has been appointed chairman of a committee to adopt insignia to distinguish the medical corps of the Army from officers in other branches of the service, and as the medical officers of the National Guard may adopt the same design he has requested the Surgeon Generals of different States to offer suggestions as to the most appropriate emblem for this purpose, and for this reason the author of this communication has been lately engaged in a critical study of this subject in all its bearings, giving due attention to the requirements of the medical fraternity in civil life as well. As a result of this investigation we find that particular symbols have in all ages been assumed by the various civilized and uncivilized families of the human race. They have been placed upon the standards and banners of tribes and nations, upon the genealogic escutcheons of kings and the nobility, and for centuries they have been borne by members of many social, religious, literary and scientific organizations; by those of numerous and diversified trades or guilds, as well as by various civil and military officials as an expression of their position in the world or of their rank and special line of duty. In view of these facts we ask why should not physicians, although incased, like the knights of old, in the close armor of medical ethics, have at least the privilege in the exercise of their life-saving mission of proclaiming to the world the secret of their identity or nature of their vocation by means of some mystic heraldic emblem. While it is universally understood that the great mission of the medical profession is the protection of life, and while this should be symbolized, the insignia should also be expressive of the ancient origin of the noble art of healing. Early insignia were usually very simple, the colors in strong contrast and their form and outline such as could readily be distinguished even in the dust and confusion of battle. In order that our insignia,

as an emblem of neutrality, might be of international significance its claim to recognition should depend upon its form, design and coloring, and not from bearing upon its face any printed letters, words, motto in Latin, or phrase in the language of any nation. To meet this requirement the outlines of such a device are here represented. In order to protect the medical profession in its use for any other purpose than hereafter designated, as well as to protect manufacturers in its construction and sale by unauthorized parties and also in order to secure uniformity in the appearance of the emblem essential to its general recognition Letters Patent would be required.

The shield, as the most obvious piece of protective armor, was that upon which symbols were first displayed. For this reason it is believed that in the general approval and adoption of medical insignia, not only in our own country but throughout the world, the form of the ancient circular or triangular shield should be selected. For esthetic reasons the edges of the emblem should present a gold border, its inescutcheon should be of dark-green color embracing as the central feature of the field a modified form of a red Maltese cross surrounded by a narrow stripe of gold. Thus in recognition of the rules of blazon in order to preserve in striking contrast the visible elements of its structure, the placing of metal upon metal

Design, patent applied for.

and color upon color is avoided as much as possible. The red color of the cross, and green color of the field are not only universally recognized as symbols of life, thus emphasizing the significance of the cross (which for reasons hereafter given we believe to be typical of the same thing), but are also the most attractive and beautiful shades in nature, and when these are associated with the form of the ancient triangular Egyptian or Grecian shields in actual use as protective armor, at the time when the "Healing Art" was first recognized as an independent and distinguished vocation, then the ancient origin and the essential object of our profession, the protection of life, would be completely symbolized and the language of the insignia would need no further interpretation. Then we would be afforded not only an ornate and conspicuous emblem of neutrality in time of war, but one easily recognized on social occasions and for professional requirements in the civil as well as the military pursuits of our profession. But why should the cross be adopted as the essential feature of our insignia? In answer to this it may be stated that throughout the entire range of medieval decorative art the cross sign exhibiting an endless variety of form, proportion and adornment has exercised a most powerful influence. Referring to this subject Charles Boutell has written as follows:

"With the triumph of Christianity the cross at once was recognized as a universal symbol of the highest dignity and honor. It was made of the most precious material, enriched with the most costly gems and exquisite art. The cross became the most prominent ensign upon royal diadems and it gave both their form and their name to the noblest insignia of knightly rank. The cross crowned the scepters of princes, and the greatest warriors were proud to see the cross as well in the hilts of their swords as on the banners under which they fought." In private life also the cross was held in corresponding estimation, and accordingly the most beautiful and most prized personal ornaments appeared in some cruciform type. Thus was art taught to aid in realizing the enthusiastic sentiment of Justin Martin when he said "The sign of the cross is impressed upon the whole of nature. There is hardly a handicraftsman also but uses the figure of it among the implements of his industry. It forms the part of man himself, as may be seen when he raises his hands in prayer." In the Middle Ages the cross sign was universally held to be the special and distinctive symbol of Christianity, as to the present day the cross and the crescent are symbols which distinguish the faith of the Christian from that of the Moslem. While as a symbol of the Christian faith, at once preëminently characteristic and significant, the cross in various modifications of its form would naturally be adopted for many purposes and used in a diversity of ways, and while the greatest progress in medical science has been made since our crucified Savior died in order that a sinful world might have eternal life, and while in many ages and nations the vast majority of those distinguished in medical annals have been devout members of the Christian faith, and while the Geneva Cross of the Red Cross Society is now recognized the world over as its best practical application, yet it is not altogether for these reasons that we should adopt the cruciform device but because it has also occupied a prominent position and signification among the many sacred and mystic figures and symbols connected with the medical history of heathen nations of the greatest antiquity. Such certainly was the case in Egypt, Assyria, Persia, India, Greece, Rome and among the Scandinavian races of the North. If, therefore, we would learn the earliest account of the foundation, development and symbolism of that honorable vocation which in every land and in every clime has exercised for thousands of years its beneficent influence upon suffering humanity, we must turn back the pages of history until we reach those of Egypt, that old and mysterious country that first beheld the gray dawn of the world's creation and which has given birth not only to our own profession but to those arts and sciences which have shed their luminous rays over the field of human progress among civilized and enlightened nations in all ages from prehistoric days to the present time. And as an important reason for the expression of the main feature of this design it should be stated that a study of the hieroglyphics which constitute the sacred characters of the ancient Egyptian language in its classical phase, as found upon the earliest monuments and vases of that strange people at an age corresponding with the birth of our profession, reveals the curious fact that the cross was the ideographic sign or symbol of life. Again, we find the symbol or crucial sign of the old Olympian god, which to-day stands at the head of every medical prescription, has been handed down through

the ages from the early Greek and Roman physician to typify their invocation to that ancient heathen deity while in the exercise of their life-saving mission, and with a remnant of the old superstition still clinging to it this sign will doubtless continue to be used for centuries in the future in order that the early origin of the profession we represent may be remembered. A still more extended research among the histories and other records of ancient and modern nations with reference to the subject of medical symbolism leads to the conclusion that the crucial sign in its various forms and combinations, including the caduceus, the emblematic staff and serpents still familiar to us as part of the imprint on the title page of early and more recent medical books, are all more or less expressive of the same idea and that they are but typical outgrowths of one and the same thing. For this reason the writer, with others who have given the subject much attention, believes that the cruciform symbol somewhat modified would not only meet with very general approval but should be universally adopted as the most significant emblem of medicine in all its practical application to art, literature and civil or military organizations, affording as it does a proper emblem of the "Healing Art," fitting in its origin, significance, and, to some extent, in its actual use by civilized humanity. In this connection it is a matter of interest to know that the original idea in the international adoption of the Red Cross banner at Geneva, Switzerland, in 1864, was based on the needs of the wounded in battle, and the extent of its neutral service since this time throughout the world constitutes the most marvelous achievement in all the history of medicine. During the last thirty years this Red Cross banner has been on the fields of conflict in the wars between Prussia and Austria, France and United Germany, Russia and Turkey; in Servia, Macedonia, Roumania, Montenegro and Spain. It has also done service on fields of conflict in Abyssinia, Tunis, Morocco, the Transvaal, Dahomey, the Congo State, Zululand, Egypt and Soudan. In Asia the French have carried it in all their movements in Cambodia, Tonquin and Siam; the British into Burmah, the Dutch into Java, and the Japanese into Corea and China. In South and Central America this symbol of international beneficence has been borne in field service in Brazil, the Argentine Republic, Chile, Peru, Bolivia, Guatemala and San Salvador. And while it is fitting, therefore, that the primary and central feature of our insignia should be the crucial symbol typical of that divine gift of which we are the earthly guardians, a well founded objection has been urged against the common Geneva or Greek Cross because the arms of this are of equal size and the great mass of red color in and about the center causes an apparent lack of proportion by making the middle square look larger than its actual size. To correct this optical illusion it has been deemed best to substitute a modified form of the Maltese Cross which is lighter in the center and, therefore, presents a more pleasing feature. As an insignia for the Army it is suggested that the arms of the cross be made in the form of an ancient spear head, and for the Navy that they terminate in the form of an anchor. For use on military or naval uniforms the triangular escutcheon could be made of handsome shades of embroidered gold, or other durable material set in gold, and worn on the collar of the coat or shoulder knots and somewhat enlarged as an ornate decoration of officers' housings or saddle cloths. For those members of the medical profession not connected

with the Army or the Navy the insignia can be made in colored or enameled gold and with essentially the same features of the design also of other durable material more or less expensive so that the cost of the emblem would range in price anywhere from twenty-five cents to as many dollars. Both the circular and the triangular shields may be reduced in size and could be made from rolled or solid colored or enameled gold; either would be ornate and could be obtained at a moderate cost. The circular shield should be worn as a lapel button; the triangular shield as a scarf pin; the latter could be set with jewels, the cross of garnets or rubies with a small diamond in the center, but would be somewhat expensive. The accompanying engravings only show the general outline of these insignia, but illustrations in colors with prices according to material and finish may be obtained by correspondence with the writer.

250 N. Illinois Street.

FIBROMYOMA COMPLICATING PREGNANCY : FIBROMA OF VAGINAL WALL.

Read before the Chicago Pathological Society, Dec. 9, 1895.

BY J. B. MURPHY, M.D.

CHICAGO.

FIBROMYOMA COMPLICATING PREGNANCY.

Nettie S., age 39, colored, married, admitted to the Cook County Hospital Oct. 19, 1895; family history negative; was married two years ago, no children, no miscarriages nor abortions; has always enjoyed excellent health with the exception of the present trouble. Menstruated at about 14, was regular, fairly profuse, lasting about four days; no clots, never hemorrhage. Present illness began in July, 1895, with a cessation of menstruation. It has not reappeared since. Has not had sexual intercourse for three or four months. After the suppression of the menses, noticed a tumor just below the umbilicus. This has rapidly increased in size since that time. It has not been accompanied with pain. There has been no backache; the greatest discomfort has been produced by pressure of the tumor against the edge of the ribs. No urinary symptoms; there has been no discharge.

Physical examination: Patient well nourished; large physique, considerable adipose, abdomen very markedly distended and irregular in contour. Nodular growth can be felt in the abdomen, extending above the umbilicus, and especially to the right side, where it presses against the margin of the ribs. One of the nodules below the umbilicus is about the size of a child's head, of hard consistence and fairly movable. The whole mass can be moved laterally about two and one-half inches, but not up or down. In the median line, from two inches below the umbilicus to the symphysis, fluctuation can be felt. It is apparently deep-seated, and surrounded by an irregular margin. No fetal heart-sounds nor placental souffle can be heard. Vaginal examination reveals a large hard mass, entirely filling the pelvis. The os can be felt above the symphysis. By pressing the tumor up, the sound can be introduced into the uterus two and one-half inches, but not farther, it being extremely difficult to get the os in position for the introduction of the sound. The tumor in the pelvis is very firm, smooth on surface, and of very hard consistence.

Diagnosis: Uterine fibroid, with cystic degeneration. The rapidity of growth and the absence of the history of hemorrhage somewhat oppose the diagnosis of fibroid, but this was explained subsequent to the operation.

Celiotomy: Oct. 25, 1895. Tumor found to be free from adhesions. On lifting it out of the abdomen, through a very long incision, and turning it to elevate the large nodule out of the pelvis, the left broad ligament ruptured close to its attachment to the tumor. There was profuse hemorrhage for a few seconds. The ligament was clamped with a long pedicle forceps, broad ligaments ligated and excised. The uterus was situated on the anterior surface of the pelvic portion of the tumor, and was about six and one-half inches in length. An elastic ligature was placed upon the stump, allowing the cervix to remain, so as to treat the pedicle externally. Two large pedicle forceps were placed above the ligature; uterus amputated. There was no blood in the pelvis. The parietal perito-

neum was sewed to the cervix, all the way around, just below the elastic ligature. The abdominal wound was closed down to the pedicle, packed around with iodoform gauze and dressed antiseptically.

Time for operation, thirty-two minutes. The mass weighed six pounds six ounces; it consisted of a large irregular fibroid, growing from the posterior wall of the uterus. The uterus was enlarged about six inches and contained a sac of fluid. When opened, a fetus of about three months was found in the sac, which had not been ruptured. The question of pregnancy had been thoroughly considered before operation, and thought impossible from the patient's statements and the absence of physical signs.

The impregnation accounted for the great rapidity of the growth, it being borne in mind that the patient had never noticed the tumor until July.

The patient made an uninterrupted convalescence; she did not vomit from the anesthetic, and at no time did her temperature reach 100 degrees. The highest pulse rate was 96, and that was immediately after the operation. There was no secretion from the stump, which remained perfectly dry for fifteen days, when a slight serous exudate appeared at its base—the line of separation. The pedicle sloughed on the twenty-seventh day after the operation; patient is now sitting up in bed. This completes a series of ten consecutive abdominal hysterectomies with ventral fixation of the

FIGURE 1.

pedicle, for large fibroids, not previously reported, all of which recovered.

That pregnancy should complicate uterine fibroma, is not surprising, as Gusserow, in quoting Bayle's statistics, states that twenty of every 100 women over 35 years of age have fibromata of greater or lesser size; and Klob states that 40 per cent. of all women over 50 years of age have fibromata.

That pregnancy does not appear more commonly with fibroma, is accounted for, 1, the fibroma itself tends to sterility, as it produces a pathologic condition of the endometrium, except in the sub-peritoneal variety; 2, that the fibroma does not attain a considerable size in the majority of cases, until after the child-bearing period is past; and 3, that the fibroma in the great majority of cases does not produce any disturbance during the period of gestation, and in many cases does not complicate labor. If it has attained a marked size before impregnation, its development is greatly enhanced by the pregnancy. The variety of fibroma in which the muscular element predominates over the fibrous, increases most rapidly under the stimulus of pregnancy. The tissue becomes edematous and doughy, as may be noted in the posterior wall of the uterus and the portion of the tumor attached to it, in the specimen presented.

The uterine fibroid of large size rarely admits of the completion of the period of gestation. It usually terminates in abortion, hemorrhage, impaction in the pelvis, labor pains, placenta previa, rupture of the uterus, death of fetus or sepsis. That the presence of fibroma with pregnancy may not deserve surgical attention, was well established by Theodore Landau (Volkmann's *Sammlung klinische Vorträge*, No. 26, Neue folge). He expressed himself in the following words:

"A myoma which rests in or on an impregnated uterus, does not of itself, demand the attention of the surgeon. Only when the tumor produces unpleasant symptoms is active interference indicated. The principal of these unpleasant symptoms are mechanical or pressure symptoms, as incarceration of the uterus in the pelvis, galloping increase in size of growth, nephritis, uremia, ascites, etc., as well as the reflex manifestations of pressure, cardiac, respiratory and gastric. When these disturbances are sufficiently severe to demand the physician's attention, the question arises—What shall be the procedure? Will it be an enucleation of the fibroma, an induced abortion, an abdominal hysterectomy, or

FIGURE 2.

an abdominal extirpation of the fetus, without the removal of the uterus and appendages? The selection of operation will depend on whether the immediate emptying of the uterus is necessary, and if so, whether it is possible for the fetus to pass from the uterus, through the cervix and vagina; or, whether it is desirable to have the tumor itself removed, at the same time that the patient is freed from the fetus. When the pelvic passage is blocked, the only question to be considered is laparotomy."

This statement was made three years ago. The improvements in technique and statistics of abdominal hysterectomy have produced an entire change in the conditions which guide us in our selection of procedure. It is questionable whether induced abortion in the presence of a large fibroid is not as serious a procedure to-day as an abdominal hysterectomy in the hands of an expert operator. It is certain that if the tumor itself demands removal, it is better that the tumor, uterus and fetus in situ should be removed at once, without attempting a previous abortion. The recognized dangers in parturition of a myomatous uterus are atony, hemorrhage, peritonitis, gangrene of the tumor, rupture of the uterus and retention of the placenta. These dangers are all

present with abortion, some in a lesser and some in a greater degree than in labor at full term. The dangers of sepsis and hemorrhage are very much greater in induced abortion, while the dangers of rupture and gangrene of the tumor are less. Gusserow reports a death from intraperitoneal hemorrhage in induced abortion, from rupture of the veins around the tumor.

The statistics for simple myomectomy, without removal of the uterus collected by Landau, represent eighteen cases at different periods of gestation, ranging from twelve weeks to seven months, and in the hands of fourteen different operators, show four deaths and seven miscarriages. It was first performed by Péan, Dec. 15, 1874. It can be seen that the mortality for this operation is 22 per cent. and for abortion about 40 per cent. (Würkert¹ collected twenty-seven cases with seven deaths), not encouraging from either standpoint, notwithstanding the beautiful results produced by Schroeder, Landau, Frommel (four cases and one death), and others. The same author collected eighteen cases of super-vaginal amputation of an impregnated myomatous uterus at different periods of gestation, ranging from two to eight months, by different operators, with seven deaths, a mortality of about 39 per cent. (first performed by Kaltenbach, March 21, 1880). The operations of enucleation and amputation, from these statistics, are to be considered very grave undertakings, both for the life of the fetus and the life of the patient. Still, these statistics were collected before 1890, and the operation of abdominal hysterectomy in that period had a much greater mortality than now. It is to be hoped, therefore, that the statistics of the future, as well as of the past two years, will show a great improvement in the results of the amputation of the gravid myomatous uterus, over the period preceding 1890. Landau concludes: "Hysterectomy should be the operation of selection, in submucous, intramural and multiple fibroid, enucleation coming in question only where the tumor is pedunculated or of small size, and subserous."

The difficulties of operating on the impregnated uterus, contrary to belief, are less than in the non-impregnated, and Hoffmeyer says whoever has seen an operation on the gravid uterus must admit that this statement is true. The vessels are larger, the uterine body is lifted up out of the pelvis and the ligaments are more easily reached in the impregnated than in the non-impregnated uterus. The danger following the operation, the same author says, should be less, if care be taken to remove all of the placenta and membranes.

For operation, fibromata are conveniently divided into 1. impacted pelvic myomata. These are the most favorable for operation and they usually originate from the cervix uteri and can be enucleated through the vaginal wall, without opening the peritoneal cavity. This procedure, says Chrobak, should always be followed, except where the tumor is larger than a child's head. 2. Extra- or retro-vaginal impacted fibroids. These may originate in the cervix, or in the lower portion of the corpus uteri, and are usually in the process of the enlargement of the uterus, lifted out of the pelvis into the abdomen (Spiegelberg), and are removed by laparotomy. This may occur, even though they be retro-vaginal primarily, and originate from the cervix. 3. Abdominal fibroids. The latter usually originate from the body of the uterus, and are removed by celiotomy.

When should the operation be performed? In the process of enlargement, the uterus lifts itself out of the pelvis; the fibroid may remain in the pelvis or accompany the uterus. The symptoms of impaction, as a rule, are transitory, as the uterus accommodates itself to its surroundings. If, however, these symptoms persist, they must be relieved, either by lifting the uterus and tumor out of the pelvis, or by enucleating the tumor. The rule laid down by Schroeder is that the operation should be postponed as late as possible. He says the prognosis of hysterectomy is more favorable, particularly of retro-cervical myoma, the later in pregnancy it is performed, and most favorable, if performed at the end of gestation, because at this period we jeopardize the mother less, and favor the preservation of the child. When the period of gestation is complete and abdominal section is indicated, we must then decide whether it shall be Cæsarean section, Porro or hysteromyomectomy. The statistics of the Cæsarean section with fibroma show the results to be extremely discouraging; the majority of the cases terminated fatally, even with Säger's method. The Porro, without the removal of the tumor, can be accomplished in only a small number of cases and should not be attempted. Hysteromyomectomy is the most desirable as well as the most favorable, both to the mother and the child. The question of treatment of the pedicle, whether it be extra or intra-peritoneal, or a total extirpation, must be decided by the individual operator, as each can obtain better results with the method with which he is most familiar. True, the extra-peritoneal variety tends to longer convalescence, but it has the advantage of leaving the peritoneum practically without an abrasion.² Gusserow collects in all 228 cases; the mother died in 123, a mortality of about 54 per cent., and 67 children, a mortality of 30 per cent. This includes the operations performed in the pre-antiseptic period, and a few in the antiseptic period, but does not include any cases of the aseptic era. Chrobak in 1893 successfully treated a case of this kind, in which he performed the total extirpation on the three-month impregnated uterus with internal treatment of the stump. From Schroeder's standpoint, the most desirable time to operate is at the completion of the period of gestation, and the most favorable operation a hysteromyomectomy.

In the case here presented, the indication was for immediate hysteromyomectomy, as it was not possible to even sound the uterus from the vagina, and delivery through the vaginal route could not be thought of. The tumor was producing pressure symptoms, and pregnancy had only existed for three months. The broad ligaments were quite well elevated above the brim of the pelvis; the laceration produced in the left was caused by the great distance to which the uterus had to be elevated before the tumor, which was situated deep in the pelvis, could be turned out. The application of the ligature and clamps was less difficult than in the average abdominal hysterectomy where pregnancy was not present. The statistics collected by Gusserow are certainly not encouraging for allowing the pregnancy to continue to the full period of gestation. It would seem that the operation at the seventh month should give more favorable results to the mother and scarcely less to the child, as

¹ Centralblatt für Gynecologie, No. 45. Page 1056, 1893.

² This can also be accomplished by the total extirpation, with only a line of suture in the peritoneum in the floor of the pelvis.

the mortality to the latter is already 30 per cent. The cases reported by Dr. Thad. A. Reamy, of Cincinnati; Dr. Wm. J. Taylor, of Philadelphia; Dr. Henry B. Stehman, of this city; Dr. Chrobak, of Vienna, and the case here reported, are illustrations of the results that may be obtained in early hysteromyomectomy where the tumor is complicated by pregnancy.

FIBROMA OF VAGINAL WALL.

In the year 1882 there appeared from Keimwächter, an article on "Vaginal Myoma and Fibroma" (published in the *Zeitschrift für Heilkunde*, Band iii, S. 335, Praag), in which he collected fifty-three cases. It is the largest collection that I have been able to find. Breisky, in the year 1886, added five to this number (*Die Krankheiten der Vagina, Deutsche Chirurgie*, Lief. 60, S. 163), which included the cases of von Hermann, two from Gaye, one from Casewell, and one of his own. In addition to these, I find one from Hasenbalg (*Zeit. für Geb. und Gyn.*, Band 23, Heft 1, p. 52), and one from Archibald Donald (*Med. Chron.*, January,

FIGURE 3.

1889, p. 103). The one reported by E. Hasenbalg was polypoid in shape. Of the total number, twenty-nine were in the anterior, twelve in the posterior, five in the side; others not given. The tumor may reach a considerable size. Oliver and Jacob's cases weighed a kilogram. In two old cases reported by Baudier and Gremler, the tumors weighed ten pounds. They are more frequently sessile than pedunculated. The development of the tumor is extremely slow. It may be observed at all ages. Martin reports a case in a child at birth. Traetzl found one in a child 15 months old. It produced obstruction of the urethra and rectum. They are most commonly detected at middle age, and are often found in old people, where they have existed for many years. The symptoms produced by them are merely mechanical, *i. e.*, pressure upon the bladder, urethra, rectum and surrounding tissues. One case was reported that was accompanied by uterine hemorrhage. The diagnosis is not difficult to make, the greatest care being necessary to differentiate it from cysts in the vaginal wall close to the urethra, and fibroma of the cervix uteri. It presents

a smooth, hard surface and can be distinctly separated from the uterus in the majority of cases. When located in the anterior vaginal wall, it usually begins at the urethra, close to the sphincter, and spreads laterally between the mucous membrane, as in the following case, *viz*:

S. B. was admitted to the Mercy Hospital Oct. 17, 1895. Family history negative. About four years ago, patient noticed that a tumor projected from vagina. It grew with moderate rapidity, and when about the size of an apple, it ulcerated on the surface and gave a very offensive discharge. The tumor up to this time had not caused any unpleasant symptoms, with the exception of a heavy, dragging sensation in the pelvis. She was operated on at that time (two years ago) and the protruding portion removed. About six months ago, she discovered that a prominence still remained in the anterior wall of the vagina. There was no pain nor discomfort. It has gradually increased in size: there were no urinary symptoms.

Examination: The smallest portion of the tumor is apparently attached to the wall of the urethra, in the median line.

FIGURE 4.

It extends from that point to the left, out to the margin of the pelvis. It can be distinctly separated from the uterus, to which it is not attached. The largest portion presses upon the left side of the pelvis, in front. Rectal examination shows that the tumor is about an inch from the cervix uteri, and hugs the left pelvic wall closely.

Diagnosis: Fibroma of vaginal wall.

Operation: An incision was made in the anterior vaginal wall, beginning at the urethra, and extending to the left an inch and a half. The surface of the tumor was exposed, and it was readily enucleated with the finger from the submucous vaginal tissue. Cavity packed with iodoform gauze. Uninterrupted convalescence. The tumor measurements are, $9\frac{1}{2}$ c. long, and 5 c. in diameter; the thick end being 4 inches and the smallest $2\frac{1}{2}$ inches. It weighs 57 grams.

Microscopic examination: Myxofibroma of the vagina. The tumor is a typical fibroma, the seat of fatty and mucoid infiltration. The sites of fat masses are shown at A. The mucoid infiltration is not even. This material did not stain with iodine, nor with methylen violet. With eosin it stained somewhat more deeply than the other tissues though not markedly so: it was soluble in water. The conclusion was that it was mucus. The number of vessels in the tumor had been very large. Two factors, endarteritis and infiltration obliterated many of them, and greatly diminished the caliber of others. Some entirely obliterated are seen at B. Others partially excluded at C.

NOTES ON THE DISTRIBUTION OF *BACILLUS COLI COMMUNIS*.

BY JOSEPH MARSHALL FLINT, S.B.

UNIVERSITY OF CHICAGO.

The peculiar but obscure relations existing between the bacillus of typhoid fever and bacillus coli communis have made it necessary to acquire a fuller knowledge regarding the natural distribution of the members of the coli-typhoid group. It has sometimes been asserted, although on insufficient evidence, (Blachstein, Kellogg), that many of the lower animals normally harbor intestinal bacteria capable of causing typhoid fever, and in this connection the recent investigations of Lösener¹ upon the occurrence in nature of bacteria possessing the characteristics of the typhoid bacillus having no apparent connection with an antecedent case of typhoid fever seem to be especially noteworthy. With a view to throwing light upon some of these questions of distribution, the following study was undertaken.²

The fact that bacillus coli is normally found in the intestines not only of man, but also of several domesticated animals has been well established by the researches of Escherich,³ Smith,⁴ Tremblin,⁵ Dyer and Keith⁶ and others. My own studies were chiefly upon material procured through the kindness of Mr. C. B. DeVry, while head-keeper of the Lincoln Park Zoölogical Gardens, Chicago. The feces, obtained as fresh as possible in each case, were collected with bacteriologic precautions and transported as speedily as possible to the University laboratory where they were plated at once. All told, the feces or intestinal contents of twenty-eight animals were examined; in fourteen of these bacillus coli was found either in pure culture or in numbers greatly preponderating over the other forms present. In several cases, *e. g.*, in the feces of the moose, I have found varieties resembling bacillus coli very closely, but these have been for the time being neglected, my aim being to discover the presence of the typical, unmistakable bacillus coli. Minor variations, however, appear in the tables following:

	Source.	Fremlin.	Dyer and Keith.	Smith.	Flint.
Man	Feces	+	+	+	+
Elephant	Feces	+	+	+	+
Buffalo	Feces	+	+	+	+
Cow, calf*	Feces	+	+	+	+
Horse	Feces	+	+	+	+
Moose	Feces	+	+	+	+
Elk	Feces	+	+	+	+
Reindeer	Feces	+	+	+	+
Llama	Feces	+	+	+	+
Cashmere goat	Feces	+	+	+	+
Lion	Feces	+	+	+	+
Tiger	Feces	+	+	+	+
Leopard	Feces	+	+	+	+
Bear	Feces	+	+	+	+
Black wolf	Feces	+	+	+	+
Wild cat	Feces	+	+	+	+
Dog	Feces	+	+	+	+
Swift fox	Feces	+	+	+	+
Cat	Feces	+	+	+	+
Swine	Feces	+	+	+	+
Raccoon	Feces	+	+	+	+
Kangaroo (no growth)	Feces	+	+	+	+
Rabbit	Feces	+	+	+	+
Cubana pig	Feces	+	+	+	+
White rat	Intestine	+	+	+	+
Mouse	Feces	+	+	+	+
Fish otter	Feces	+	+	+	+
Stork	Feces	+	+	+	+
Brown pelican	Feces	+	+	+	+
Dove	Feces	+	+	+	+
Snake	Intestine	+	+	+	+
Frog	Intestine	+	+	+	+
Nocturnal	Intestine	+	+	+	+
Turtle	Intestine	+	+	+	+
Perch	Intestine	+	+	+	+

The growth of these forms on gelatin and agar plates was typical and needs no comment. No active movement in the hanging drop was observed in well-developed colonies on gelatin and agar plates, but individuals from the younger colonies frequently exhibited rapid movements of translation. Upon potato the characteristic rich, yellowish-brown growth took place. In all comparisons of the growths on various media I have found it absolutely essential to conduct parallel cultures, since comparatively trivial changes in composition, age and temperature lead to results which are not strictly comparable.

The more important tests made are presented in tabular form:

	Nitro-indol test.	Formalin bouillon.	Gas production § (Glucose agar.) Glucose bouillon.	Coagulation of milk.	Dunham's rosolic acid medium. 24 hours.
Human feces	+	cloudy	+	+	alk.
Moose	+	cloudy	+	8 days	alk.
Lion	+	cloudy	+	3 days	alk.
Bear	+	cloudy	+	2 days	
Black wolf	+	cloudy	+	2 days	
Llama	+	cloudy	+	2 days	
Leopard	+	cloudy	+	8 days	alk.
Tiger	+	cloudy	+	2 days	alk.
Swift fox	+	cloudy	+		
Raccoon	+	clear	+		
Fish otter	+	cloudy	+		
White rat	+	cloudy	+	18 hours	
Snake	+	cloudy	+	quickly	
Frog	+	cloudy	+	slowly	alk.
Turtle	+	cloudy	+		

Investigation into the diet of the animals examined throws no light upon the reason for the presence of bacillus coli. The meat-eating animals, with the exception of the wild cat, have been found to contain bacillus coli in the feces, but it has been observed not uncommonly in those of the herbivora also.

Black wolf, + meats.
 Swift fox, + meats.
 Tiger, + meats.
 Wild cat, - meats.
 Leopard, + meats.
 Lion, + meats.
 Calf (month), milk. Probably fecal contamination.
 Fish otter, + fish, twice daily.
 Raccoon, + vegetables.
 Goat, - vegetables.
 Kangaroo, vegetables.
 Bear, + vegetables + bread.
 Llama, + vegetables + hay.
 Elk, - hay and oats.
 Reindeer, - hay and oats.
 Horse, hay and oats.
 Cow, + grass and hay.
 Buffalo, hay and oats.
 Elephant, hay and vegetables.

The facts here brought out emphasize the eminently saprophytic character of bacillus coli. It is sufficiently surprising that the ultra typical bacillus coli should occur normally in the intestine of so many animals, living in nature under widely different con-

* Kellogg and Novy could not find bacillus coli in feces of calf, and say that it is an unsettled question whether or not bacillus coli can pass through the alimentary canal of the cow. Kellogg holds also that bacillus coli in passing through the body of an animal acquires biologic characters closely resembling those of Eberth's bacillus.—Mod. Med. and Bact. Review, 1891.

† Flocca found the organism in the mouth of a suckling kitten.

‡ Fremlin does not state whether it is the common rat or white rat.

§ It is perhaps possible that a more exhaustive determination of the fermenting powers of these microorganisms might have revealed differences between them which the glucose test alone did not bring to light. See *e. g.* Smith "Notes on Bacillus Coli Communis and Related Forms." *Am. Jour. Med. Sciences*, Sept., 1895.

|| "Vegetable diet" consists of ordinary market vegetables, such as carrots, turnips, cabbage, etc. Animals fed twice per day.

ditions and with intestinal contents chemically quite dissimilar. It is further clear that the statement that "the true habitat of bacillus coli and its varieties is the intestinal tract of the higher mammals" will have to be extended to cover at least the intestinal tract of the lower vertebrates. It is interesting to note, for example, that in the intestinal tract of the poikilothermus frog is found the typical bacillus coli agreeing in every respect with the form isolated from the normal human intestine, even to finding its optimum temperature at 37 degrees C. The same is true of the culture of bacillus coli isolated from the intestinal contents of the sucker and the turtle.

Bearing in mind these facts, it is obvious that deductions from the presence of bacillus coli in water are to be drawn somewhat cautiously. Its presence, like that of "free ammonia," may or may not be indicative of sewage pollution. The assumption that bacillus coli or the closely allied forms found normally in the intestine of the lower animals can cause disease in man is thus far without foundation. The facts of epidemiology, indeed, go far to rivet our attention on the connection of cases of typhoid fever and similar diseases with antecedent cases in man.

THE TREATMENT OF AURAL CATARRH IN THE LONDON CENTRAL THROAT, NOSE AND EAR HOSPITAL.

BY FAYETTE CLAY EWING, M.D.

Late Senior Clinical Assistant Central Throat, Nose and Ear Hospital — and at the London Throat Hospital; Fellow of the British Rhinological, Laryngological and Otolological Association, and of the American Medical Association.

ST. LOUIS, MO.

In a previous number, having given the treatment of the different forms of nasal discharge classified as catarrhal, at the Central Hospital, I shall now proceed to make clear the method used for the cure of those varieties of ear disease usually termed catarrh, and divided into acute non-suppurative, acute suppurative, chronic non-suppurative and chronic suppurative.

Acute Non-suppurative and Suppurative.—Since the acute suppurative is only a more advanced or severe form of the non-suppurative, for clinical convenience they will be discussed together. Children who are victims of adenoids in the naso-pharynx are most susceptible to acute catarrh. Frequently the disease progresses no further than the non-suppurative variety. When due to adenoids they are removed under nitrous oxid gas, the curette generally being invoked, followed by a good finger scraping. When the faucial tonsils are enlarged they are removed first, at the same sitting, with a Mackenzie guillotine, the whole operation lasting only about half to three-quarters of a minute. There has never been a dangerous hemorrhage from tonsillotomy at the Central Hospital. When the tonsils are very large a cold wire snare is employed instead of the guillotine. In exceptional cases some of the surgeons use the Lowenberg forceps. The advantages claimed for the gas over chloroform are that it is quicker, and the patients recover sooner, and without the undesirable after effects. After the operation the patient is kept indoors, and fed on slops until the bleeding surface is somewhat healed. When

the exciting cause of the aural mischief is the adenoid hypertrophy, the catarrh generally gets well without further treatment, after the growth has been removed. The majority of patients do not come to the hospital until after the membrane has ruptured. Previous to this occurrence the pain is generally very severe, to relieve which several leeches are applied over the mastoid and in front of the tragus. These are supplemented by warm, wet cloths, which promote bleeding and dispel pain. Poultices and blisters are never applied. Instillations of morphin gr. ij to the ounce, or a 10 per cent. solution of cocain, are dropped into the ear if necessary. When ear drops are used they are warmed by first dipping the spoon that is to contain them in hot water, and then pouring a small amount into the meatus. When the acute symptoms have subsided the ear is kept clean by syringing with a lotion composed of boracic acid gr. x to one ounce of water. For a time, daily inflation with the Politzer bag is practiced. Before perforation, if the membrane is found to be bulging and tense, indicating serum behind, an incision is made and the contents let out. Before performing this operation the membrane is anesthetized, as far as possible, by the introduction of a pledget of cotton soaked with a 10 per cent. solution of cocain. Assistance is required to steady the head, preventing the removal of the spot from the line of light at the critical moment. Careful drainage is promoted, and the patient cautioned not to stuff the ears tightly with cotton-wool. Simple, uncomplicated suppuration is generally cured in a short time by careful syringing with the above boracic solution. The ears are carefully wiped afterward and a thin pledget of cotton-wool introduced. The "dry treatment" is seldom or never prescribed.

Chronic Suppurative.—The idea kept constantly in the patient's mind in treating the malady is cleanliness. The ears are required to be syringed at home one or more times daily with an alkalin solution, the one usually employed being composed of:

R. Sodii sulph.	3 ij.	60
Aquæ.	3 x.	300

Misce.

Or

R. Sodii bicarb.	gr. c.	6
Acidi carbolic.	5 ij.	8
Aquæ.	3 x.	300

Misce.

The special recommendation of an alkalin wash is that it dissolves the cerumen and mucus. After the cleansing wash an instillation is employed composed of:

R. Acidi boracici	grs. xvi.	96
Aquæ	3 i.	30

Misce.

Or if a more astringent effect is desired, the following:

R. Liquor plumb. subacet.	5 iij.	12
Aquæ	3 ij.	60

Misce.

Or

R. Zinci sulph.	grs. v.	30
Aquæ	3 i.	30

Misce.

As the case progresses inflation by the Politzer bag is practiced to prevent adhesion of the membrane of the inner wall of the tympanum, and ankylosis of the ossicles. It also assists drainage. The most frequent complication is extension of the inflammation to the mastoid cells, manifesting itself in pain, tenderness and swelling. The pain and swelling may be

¹ Arbeiten a. d. k. Gesundheitsamt, XI, 1895.

⁴ Bulletin No. 6 of the Bureau of Animal Industry, Washington, 1891, pp. 9-41.

⁵ Archiv f. Hygiene, XIX, (1893) p. 295.

⁶ Technology Quarterly, vol. VI, No. 3, October, 1893.

present without the cells themselves being involved, in which case an incision is made down to the bone, over the site of the swelling. Should the cells show involvement, a flap of skin is turned back and an opening made into them with a small trephine designed for the purpose, or with a sharp gouge, generally the latter instrument. After they have been well exposed the cavity is washed out with a 1 to 2,000 solution of bichlorid of mercury, or the following:

R. Hydrarg. biniodid	gr. $\frac{1}{4}$.	015
Sodii iodid.	gr. $\frac{1}{4}$.	015
Aque	$\frac{3}{4}$ i.	30

Misce.

Care is always exercised that the solution pass into the cavity and out of the external meatus. Drainage tubes are inserted, and the ear kept carefully syringed. The tubes remain until the discharge ceases. The further complications that may attend chronic suppuration are thrombosis of the lateral sinus, cerebral abscess and meningitis. Cerebral abscess is opened and the pus let out, and the others are treated on general principles. Constitutional treatment and general hygiene are carefully looked after.

Chronic Non-suppurative.—Realizing that non-suppurative catarrh in the large majority of cases is the result of pathologic changes in the post-nasal chamber, and that a catarrh originating here, through extension into the Eustachian tube may produce a stenosis of its caliber through chronic inflammatory thickening of the mucous membrane, special attention is directed to the treatment of post-nasal catarrh and concomitant or producing conditions. Inflation is practiced regularly, in order to keep the tube patent and prevent fixation of the ossicles, and also for the purpose of supplying the normal quantity of air to the tympanum. When only one ear is affected or there are any special reasons why both tympana should not be inflated, the catheter is used. While the inflations are in progress the membrane is carefully watched for evidences of relaxation, in which case they are not done so often. In order to stimulate the lining membrane of the tube to a healthier condition vapors are employed, a favorite being:

R. Chloroformi	āā 5 ij.	8
Etheri acet.	ad 3 i.	30

Misce.

A few drops of this solution are blown into the middle ear through a Dundas Grant¹ self-inflator, or from an ordinary Politzer bag with an expanded nozzle. The inflator is a simple and inexpensive instrument, and is supplied from the dispensary to patients. It consists of a glass tube about two inches long, contracted at both ends. The expanded center contains cotton, and one end serves as a mouthpiece, while to the other is attached a piece of rubber tubing about fifteen inches long. A smaller piece of glass tubing is connected with the other end of the rubber, and over this fits a rubber nosepiece. After a few drops of the ethereal mixture is dropped on the cotton the patient fits the nosepiece in one nostril, closing the other with his fingers, and blows steadily with puffed-out cheeks, until he feels the membranous movement. The *minimum* force necessary to produce this result is advised. The vapor can be specially directed to one ear by stopping the other, and turning the one to be inflated upward. Chloroform greatly facilitates the passage of air through the tube. Dr. Grant claims brilliant results from this method of inflation and medication,

where Politzerization produced no appreciable benefit, and he attributes the good results to the *minimum* pressure employed. In long continued inflation the advantage of the Grant method is obvious. The Eustachian bougie is seldom used in this hospital. Massage is advocated in desirable cases, the instrument being Siegle's pneumatic speculum or some modification of it.

COMMON GROUND OF MEDICINE AND DENTISTRY.

Read in the Section on Dental and Oral Surgery, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY JOSEPH ROACH, M.D.

BALTIMORE, MD.

At the outstart, definitions are necessary, and it is well to state, that the term medicine includes all that the average practitioner would expect to do, who did not think of establishing himself in any one of the numberless so-called specialties of medicine. For convenience, I will call dentistry one of these specialties, although it might be shown, that it is so distinct and so peculiar as to make it well nigh a thing by itself and difficult to place with any of the specialties. If it be surgery, many operations consist in cutting out decayed parts in an organ so constituted that it has of itself no power to make use of the vis medicatrix naturæ, found in other organs and tissues, and with filling the same with some foreign material. The sole use of that material is to prevent further progress of the disease and to serve as a substitute for grinding and cutting food.

There is no blood, no ligation of arteries, no stitches, no sutures are made; and the patient is dismissed, on the spot, cured by a surgery, of which it might be said, that its only relapses are due either to mechanical imperfections in the operations or to inherent faults in the structure repaired. True it is, that one department of this work trenches on surgery thus far; that in the exploration of the canals, occupying the roots of teeth, either by a failure to remove living tissue or a failure to disinfect any decomposed tissue, a local sepsis may occur, resulting in abscess and occasionally invoking grave consequences. But even this does not ordinarily rise higher in the scale of surgery, than the treatment of a felon on the finger. I have thus purposely taken a low view of the daily work of dentistry for this reason. I think possibly too much pains have been taken by its membership to elevate a most useful, nay, a most indispensable calling, into a position to vie with surgery proper. I say daily work, for while it is true, that, as dentists, we are occasionally called upon to repair a fractured maxilla or even extirpate a tumor of the jaw; such operations are but occasional and in the nature of the case, it seems to me to fall as naturally into the domain of the general surgeon, as does the fracture of the femur. The true usefulness of the dental surgeon in such cases rests in his ability as mechanician to skillfully form and adjust special splints in case of fracture. This ability he forms from his daily work noticing artificial dentures or in his possessing special, cutting instruments in the form of burs, etc., for the dental engine, instruments, peculiarly adapted for his own work in removing decay from teeth and turned to occasional use as above in removing tumors. Still none the less skill-

¹ One of the surgeons.

ful, is the work of making plates, crowns, bridges, etc., where to the dexterity of the mechanic must be added the fine eye of the artist, restoring sunken features, harmonizing incongruities and above all and most perplexing of all, pleasing or failing to please the tastes of fading humanity.

But while all the above may be true, and the work of the average dental surgeon may be largely mechanical, the fact, that both the surgeon and he work on the human body, makes a bond of union between them, which is worth study, inasmuch as whatever links in this bond are found to be the common property of both, are of much greater interest than any dissimilar points.

Of the maladies of common interest I will mention those often obscure and occasionally grave diseases, that involve the maxillary sinus. This is obvious for the reason, that in such cases the dental surgeon very often is apt to be the first observer on the ground. For whether we view these diseases as arising from diseased teeth or from some more remote and obscure cause, the dental surgeon, if he be ready to take up such cases for himself or turn them over to the surgeon, is none the less called on to diagnose accurately the symptoms, that they may be treated as purely from tooth-trouble or he may proceed on some other line. It is not in the province of this paper fully to describe all the various troubles, that may arise in the maxillary sinus; but, if you will throw with me a rapid glance at its position and uses, it will be of service in following any line of treatment that may be suggested. It is situated above the so-called jaw teeth on either side of the upper jaw and extending from the first bicuspid (sometimes the cuspid) backward to the second molar of the same. Its size varies and its exterior or facial walls are quite thin, the palatal wall stronger and its floor very variable in shape and thickness. The only opening into it upward is into the nasal cavity. The situation of the cavity is surgically important, for when we consider the tendency of all mucous-membrane covered surfaces to catarrhal troubles and the position of any cavity without natural drain, shut in by bony walls, and its only outlet narrow and pointing upward, we see at a glance how the difficulty or impossibility of any natural drainage and the tendency of fluids once accumulated could give even more trouble than does occur. Indeed if we consider the tendency of catarrhal troubles to spread by continuity of surface, it seems a wonder that all cases of chronic nasal catarrh do not involve engorgement of the antrum itself. Certainly this is what one might expect. Yet it would seem that this is not only not true; but that, on the other hand, certainly from the partial view of the case taken by the dental surgeon, the lighting up of antral trouble can be traced often to diseases of the teeth, the roots of which lie under its floor.

The dissecting table reveals to the dental pathologist a curious state of affairs just here; but, in order to grasp this situation fully, it is necessary to state what comes much more closely under the observation of the dental surgeon, a fact that only the physiognomist studies, as it should be, and that is, that in inheriting our tendencies, we inherit a mixture. Small jaws with large teeth are the rule, occasionally large jaws with small teeth: the back teeth of the father, the front teeth of the mother or vice versa. The jaws are sometimes so narrow and cramped and the teeth so large, that they crowd each other and such a lack of

blood in the jaw, from non-use in mastication, makes bone and muscle without stamina. The result is, that the large teeth of the upper maxilla, the roots being formed physiologically, by addition to their length are either forced through the floor of the antrum, or else, in the evolution of that chamber from six years to twenty-one, the periosteum fails to build thickly enough to cover those roots.

They are, however, always covered by the membranous lining of this cavity, else the vessels, passing into the foramina of these teeth, would be exposed to the atmosphere. All this is not likely to involve the antrum in pathologic trouble so long as the roots of these teeth are sound, but it may be fairly stated, that more than one-half of the patients, falling into the dentist's hands, sooner or later have pulpless molars, the roots of which project through the floor of the maxillary sinus and are objects more or less irritating to the tissues against which they rest. Again in the case of molars, the roots of which do not pass through the antral floor, in the case of devitalization, an ordinary alveolar abscess may occur with the sequelæ of absorption of the alveolar plate at the tip of the root and the outflowing of pus into the antrum itself. It is true, that an abscess in such situation might not be of grave consequences, yet it is plainly a situation of risk. This may not often exist, for the reason that the widely forked roots of the upper molars and their nearness to the outer walls of bone cause development of fistulous openings, away from the antrum, yet it is a source of danger and as such should be studied. Dentists devitalize and remove the pulp from the roots of such teeth. This is a very usual, almost daily, operation. But while an earnest and faithful effort is made to perform this operation thoroughly, so attenuated are the canals of the molars, that it is not at all certain that all the pulp is removed. In such a case it is easy to see that any filling material forced into the root canal may force particles of dead tissue through the foramen and into the tissues above, inoculating these with septic matter; or if disinfectants have been used there, such as carbolic acid, corrosive sublimate, etc., may be forced through to the injury of a tissue which has, as described in the outset, no drainage in case of chronic irritation. I have said enough on this subject, I dare say, to call your attention to certain lesions of the antrum, that are common ground of observation and treatment of both dentist and surgeon, and call attention in conclusion to a case, sometimes very grave, always painful, that of an impacted and abscessed third lower molar.

The same causes to which I have already alluded, as dwarfing the upper jaw, conjoin to make the lower both small and short. In the evolution of the lower wisdom tooth, it seems less often to share in the dwarfing process than the corresponding upper tooth. In a word, it is often too large for the space between the second molar and the angle of the jaw. In consequence its eruption is so interfered with, that it may be either only partially erupted or it may be impacted at an angle against the second molar, appearing through the gum slightly or not at all. Abscess of this tooth often involves not only the tissues immediately around it, but the tissues of the throat become inflamed and grave results ensue. It is pretty well established that throat trouble of a serious, or even fatal character, has been set up by an agency seemingly so unimportant. Abscess, opening into the

pharynx, is certainly one of the sequelæ of this trouble. I have been told of cases, where the infiltration of pus between the muscles of the neck and connective tissue proceeded to the formation of fistulous openings on the stomach with ordinary results of blood poisoning.

I have said enough to indicate a common ground for dentistry and surgery in the two cases above cited. Many more might be mentioned, if time permitted, to strengthen the statement thereof.

THE DESTRUCTION OF CHILDREN'S TEETH—CAUSE AND PREVENTION.

Read by title in the Section on Dental and Oral Surgery at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY J. G. HENISTER, M.D.
BALTIMORE, MD.

The destruction of children's teeth is to me, as it must be to all of you, a source of the greatest regret, and ordinary methods have failed to overcome the difficulty. It would be useless for me to attempt to go into details as to the cause of this condition, as it must be perfectly apparent to all, who stop to consider a moment. I think the first and greatest cause is neglect and ignorance as to the proper time and means of caring for the teeth. I tell you, gentlemen, it is astonishing to see the ignorance of some parents in regard to the teeth of their children. They will come into your office with a child and point to a six-year molar with the crown nearly destroyed, and say: "Doctor I wish you would extract this little snag." You will answer, "That is a permanent tooth and should be preserved." They reply, "Oh no that is only one of the baby teeth." You insist that it is a permanent tooth and refuse to extract it, and they leave your office a look of great incredulity, go to some one else who will extract it, and you will probably never see them again. This ignorance is not confined to a few of the poor, who are unable to procure the services of a dentist but extends to others who have plenty of time and means, but who never think of their children's teeth until they are crying with the pains of toothache. There is still another class of parents, who do all that they think necessary by insisting upon the use of the tooth-brush and dentifrices, but never think of consulting a dentist, so long as the child does not complain. They make a mistake, common to a great many, that the incisors are the first permanent teeth, and thus utterly neglect the six-year molar, thereby leaving it for a year or two exposed to the inroads of caries, without any protection whatever.

Another important cause of this decay is in the use of improper foods: by double bolting in the craze for white flour and bread, the phosphates or bone-making properties are taken away, and as a consequence, the teeth of children are imperfectly developed. I suggest to my patients the use of corn bread and graham bread, and I also prescribe the "Syrup of Hypophosphites" to endeavor to check and restore the loss of the lime salts of the teeth.

I have tried to enumerate a few of the causes of the loss of the teeth of children; I now come to the methods of saving them and to the responsibility of dentists and physicians alike. I have spoken to physicians about the matter, and they nearly all disclaim any responsibility, saying: "The teeth are not in our

line, that is your work." This is a serious mistake. No physician who has the welfare of his patients at heart can afford to neglect the teeth, for in the mouth begins the process of digestion, and if the food is not properly masticated, it goes into the stomach in lumps, and gives the digestive organs there, so much work that they become impaired and unable to properly perform their functions. We have been called a "nation of dyspeptics" and the cause has been attributed to the rush and hurry of American life, in eating too much and too rapidly, but I do not think this is the entire cause. The teeth being imperfect, imperfect mastication is the result, which is an important factor in this distressing complaint. The physician says, "What can I do? You would not have me fill the teeth?" No, that is entirely unnecessary and out of his line, but he can, at least, examine the teeth of children, and insist upon the parents taking them to some careful dentist. This is not a mere suggestion; it is his duty, a sacred obligation. If the nose, eye or ear is affected, does he not examine it and insist upon the parent taking the child to a specialist? Do you not think that the teeth are of sufficient importance to warrant equal care? I think so and say that the health of future generations will, in a great measure, depend upon the preservation of the teeth now. It has been predicted that the "coming man" will be toothless and hairless, and if things continue as they have been going, this will probably be so. It has been demonstrated by scientists that deformities and malformations can be transmitted from parent to offspring. If it is so with other parts of the body, why not with teeth? Jaws are sometimes entirely stripped of teeth, and when some teeth do remain they are only vestiges of what they should be. This I think is a deformity that can be transmitted.

I have observed on several occasions that peculiarities of the mouths of parents were inherited by children: for instance, I saw a mother who never had a left superior lateral incisor. One of her sons, in fact, the only one of her children I ever saw, had the same peculiarity. So I might go on giving examples of what will probably happen if we do not save the teeth of the children. You all know that the field of action of the dentist is, in a manner, circumscribed. He can not regularly go the homes of his patients to examine their teeth, but must wait until they come to him. Now here is where the physician should do his part. He usually has the care of the child from its very infancy, and if he would occasionally make a careful examination of the teeth of his little patients, and send them to the dentist, the small cavities of decay could be filled with some simple material, and the teeth thus preserved indefinitely. A short time ago a physician, whom I know, insisted that a mother should take her little girl to a dentist, saying the six-year molars were decayed, and required filling. She was brought to me and I found that the teeth were badly decayed, and so sensitive that I had great difficulty in persuading the child to allow me to do anything to them. She was eleven years of age; if this physician had examined her mouth regularly, and insisted upon her going to a dentist the caries could not have made such progress. Dr. Bonwill, the eminent Philadelphia dentist, has said that the only way he has ever been able to do anything with the six-year molar, was to fill every tiny spot of decay. So once again I beg of physicians to watch the mouths of the children, and send them to a dentist.

Now, gentlemen of the dental profession, what is our duty? In the first place, we must endeavor to educate our patients. How can it be done? I have seen little treatises upon the care of the teeth, written from time to time by dentists and others, who have given this matter some attention, but as a rule they were too scientific for the average lay reader. What is needed, and what I would suggest is the publication, under the auspices of the AMERICAN MEDICAL ASSOCIATION, or the National Board of Dental Faculties, of a small tract or leaflet, written in plain, simple language so that any one can understand it, describing the order of the eruption of the permanent teeth, and the proper means of caring for them, and warning parents of the necessity of preserving the temporary teeth until the permanent teeth appear. These little papers could be given our patients, and I think, in this manner, great good could be accomplished. Another method that has occurred to me, is the preparation of short articles upon the care of the teeth, written in such a manner as to interest, and at the same time instruct, the children as to the necessity of taking care of their teeth, these articles to be published in juvenile papers, such as *St. Nicholas*, *Chatter-box*, *Golden Days*, etc. This is only an idea of mine, and may not be practicable. Everything is to be published with the sanction of some recognized medical or dental society, thus removing from it every semblance of quackery or advertising.

Now, gentlemen, I have presented these few ideas of mine. I have attempted nothing scientific, and have given no new and startling theories, but have endeavored to express myself in plain, simple language; and I would ask you not to hesitate in criticism of me, and my suggestions, for my object has been to provoke discussion, thereby bringing out the views of those present upon the subject. I thank you for your kind attention, and will say, in conclusion, if this paper is the means of saving only a few of the teeth now annually lost, I will be very happy.

THE MERCURIALS.

BY S. V. CLEVENGER, M.D.

CHICAGO.

(Concluded from page 366.)

Calomel.—Adopting Schmidt's¹² analysis of pancreatic juice, I found that it required 21 grams (323 grs.) of the official hydrochloric acid to neutralize 143 grams (2200 grs.) of this artificial pancreatic juice. The proportion was as 1 to 7. One part of hydrochloric acid will neutralize one and one-half parts of potassium hydrate. Then the alkalinity of pancreatic juice is to potassium hydrate as 7 to 1.5, or it requires 4.6 times as much pancreatic juice as caustic potash to neutralize the same weight of muriatic acid. Schmidt's quantities being parts of 1,000. I am thus enabled to place the alkalimetry of pancreatic juice at 4.6 parts per 1,000, which agrees remarkably with Matteucci's estimate of the lymph and chyle alkalinity being equivalent to 4.3 parts per 1,000, in terms of potassium hydrate. Bidder and Schmidt estimated the amount of pancreatic fluid daily secreted by man as 7 ounces (224 grams). This is equivalent to 10 grams (154 grs.) of potassium hydrate and sufficient to reduce 42 grams (647 gr.) of calomel into black oxid of mercury. At least it is safe to presume that an ordinary dose of calomel is converted into black oxid

of mercury as soon as it encounters the pancreatic fluid. Black oxid of mercury is one of the most unstable compounds; at bodily heat it will yield oxygen and readily be converted into metallic mercury in the presence of deoxidizing substances. Liver sugar, or the glucose formed by pancreatic juice acting upon starchy matter, is quite sufficient to convert the black oxid into metallic mercury, by deprivation of oxygen at bodily temperature.

At this stage it might be expected that calomel would act the same as blue mass, and generally speaking this is true, though the liberation of the small amount of chlorin and formation of chlorids of sodium and potassium would of itself accelerate glandular action in the gastro-enteric vicinity. The globules released from calomel average smaller than those in pill mass, though many of the spheres are quite as large.

Parrish claims that "long trituration of calomel increases its power to salivate."¹³ This pulverization may cause the liberated globules to be more widely distributed in the alimentary canal and hence prevent any tendency of the lesser globules to form larger ones. In the finer divided state the metal would be able to act more rapidly through the circulation. At 10 A.M., to a chicken weighing four and a half pounds, eighteen months old, I gave 5 grains of calomel. At noon it was sick and very thirsty; 9 P.M. I blew 10 grains more calomel into its pharynx, and at 10 o'clock P.M. killed it. It ejected four ounces of water from its mouth, mixed with the last dose of calomel I had given it, and I recognized black oxid crystals in this liquid which apparently formed above the crop. I did not expect conversion to occur at this point, but it indicated the general tendency of mercurials toward decomposition everywhere in the body instead of a formation of higher salts. The feces contained mercury globules. Mercury was distinguishable by the microscope in three out of five parts of the chicken's blood; traces of calomel and black oxid were discernible in the proventriculus and gizzard; a few crystals of the black oxid with a great many globules of the metal were found in the upper intestine, with only metal lower down; the liver contained the metal, while the mesenteries held unmistakably large quantities of the globules, ranging downward in size from those usually found in blue mass. The liver globules were small, while those in the mesenteries were large.

Frequently repeated, small doses of calomel impress the general system better since they allow reduction and absorption to occur at intervals, insuring complete reduction and absorption, and widespread dissemination through circulatory channels. This is no less true of the mercurials in general.

From remote periods it was supposed that salt and acids converted calomel into corrosive sublimate in the stomach though this has been repeatedly shown not to be the case. One of the denials was made from numerous experiments by Verne:¹⁴ "No poisonous compounds are generated from calomel in combination with such bodies as salt, sugar, citric acid, etc.; and whenever such mixtures have been followed by alarming symptoms the calomel must have been an impure article. The protochlorid of mercury is really a more stable compound than ordinarily considered, and it would appear that bichlorid is more easily converted into the proto combination rather than *vice versa*."

Upon testing the stocks of calomel in a dozen drug

¹² *Annalen der Chemie und Pharmacie*, 1894, XCH, p. 33.

¹³ *Pharmacy*, p. 290.

¹⁴ *Repertoire de Pharmacie*, June 1879.

stores in Chicago I found corrosive sublimate traces in nearly all, and in that of a few manufacturers the amount to the ordinary dose must have rendered this chlorid far from "mild." So, as Verne notes, when calomel acts harshly it is probable that it is impure by containing the bichlorid.

Further, as to the mistake that a higher salt may be formed from a lower mercurous compound Wurtz¹⁵ says: "Bichlorid of mercury is easily reduced to the monochlorid or even the metallic state by many agents. Light will precipitate calomel from an aqueous solution, and many organic substances reduce the bichlorid to calomel or even to quicksilver, especially under the influence of light." In the face of these facts it can hardly be logically maintained that calomel shows a tendency to assume a higher state of oxidation. It also appears absurd to prohibit the consumption of acidulous food while administering calomel, the more so when we consider the presence of free hydrochloric acid in the stomach, and remember that this acid reacts with calomel only at a boiling temperature.

Corrosive Sublimate.—"Mercuric salts are converted into mercurous by sugar."¹⁶ According to this view therapeutic doses of the bichlorid would change into calomel in the duodenum, but this calomel must by extremely minute division liberate much finer globules of mercury in its further reduction to black oxid and metal. But pancreatic conversion of the bichlorid into yellow oxid takes place in the duodenum, and this oxid is absorbed into the circulation, where its conversion may occur slowly into the most minute metallic globules. The fact that toxic doses affect mostly the esophagus and stomach shows that the extra amount of chlorin operates corrosively until the compound is changed by the alkaline pancreatic juice. The transformation of the yellow oxid would occur in the liver, or, if it remained long enough, in the intestines, by the glucose it would encounter, for the yellow oxid is reduced by glucose as well as is the black oxid, only less rapidly.

The bichlorid of mercury is not the only substance that will coagulate albumin, nor does it enter into chemie combination with albumin. Excess of the latter will dissolve the bichlorid, showing that the whites of eggs alone can not be relied upon as an antidote for the bichlorid of mercury.

A better antidotal method is to give at once an alkali, thus converting most of the bichlorid into yellow oxide; then white of egg, with demulcents, to allay the irritation caused by the corrosive chlorid. That this corrosive action is due to the chlorin liberated is evident from the fact that no other mercuric salt formed with another radical produces the distress peculiar to large doses of the bichlorid. Local applications of this salt are apt to be accompanied by severe effects, because the energetic material does not meet with as strong an alkali as it would in the intestines, and hence is not at once converted into a less active form. The blood, being alkaline, would gradually reduce it, but not until wide-spread, well-marked effects had been experienced. Doubtless the antiseptic property accompanies the mercury, in this soluble form, into the blood, adding to its efficiency as a remedy in syphilis, particularly where the disease is widely disseminated through the body and favoring the probability of syphilis being due to a microorganism. The sizes of the globules liberated

from the yellow oxid formed from bichlorid of mercury are incomparably smaller than those from calomel.

I have proved that corrosive sublimate is reduced partly into metal and yellow oxid in the pancreatic fluid, and part of the yellow oxid is reduced by the glucose of the intestine, the remainder undergoing slow conversion in the liver and blood, until the circulation contains the metallic form only, in a state of excessively minute division.

Chloral and chloroform each contain three atoms of chlorin, and resemble mercuric chlorid in coagulating albumin, and in having irritating and vesicating properties. Bernard believes that chloroform acts by temporarily coagulating the nerve cells. Albumin is given to antidote chlorinated water. Chlorid of lime and chlorin are both irritants; the former causes the same kind of gastro-intestinal inflammation as bichlorid of mercury. The metallic deposit is found on articles of gold worn next the person after taking mercury bichlorid, as well as in any other form. One tenth of a grain of red oxid taken twice daily in syphilis, resembles bichlorid in not causing salivation readily. In a case of corrosive sublimate poisoning, through a solution applied to the scalp in the dark by mistake for camphor water, local saturations with lime water alternated with whites of eggs rapidly disposed of the external distress, but strangury occurred, which doses of potassium iodid rapidly relieved. The kidneys had undoubtedly been occluded by the precipitated mercury globules.

The antiseptic effects of the bichlorid may be largely due to the phagocytic action of the minute globules released from the chlorin, which latter is poisonous to low plant organisms the smallness of the amount of chlorin being more than compensated by the nascent state. The metal in its mechanical form changes, and, in enveloping microorganisms, could be pictured as having ameboid peculiarities to a certain extent.

Cyanid of Mercury.—Some syphilographers prefer cyanid to bichlorid, claiming similar results from its use in the same doses, which shows that it was the mercury and not the material combined with it which exerted medicinal effects. As might be expected from the liberation of cyanogen in the stomach, none of the epigastric pains said to be caused by the bichlorid accompany the use of the cyanid. Cyanid is converted into bichlorid with hydrochloric acid. This may occur in the stomach, through the free acid there. A characteristic of cyanids is that the weakest acids decompose them with liberation of hydrocyanic acid. Its further reduction would be into yellow oxid, and the metal, as described above, under corrosive sublimate. Knapp's test for diabetic sugar with cyanid of mercury shows that sugar is very active in reducing the metal from this form, and this, I believe, explains its *modus operandi*. Differing from the other salts of mercury the cyanid is not decomposed by alkalies, so its conversion is through the stomach hydrochloric acid into bichlorid, then into yellow oxid, by the intestinal alkalies, and metallic mercury by glucose, which latter converts the cyanid direct into the metal, precipitating the same sized globules as does the bichlorid of mercury.

Mercurous Iodid. A synonym for the protiodid was the "green iodid" (which term has been dropped by the pharmacopœia of 1890 in favor of yellow iodid). Some French importations of a yellow pill of mer-

¹⁵ Dictionnaire de Chimie.
¹⁶ Miller's Chemistry, vol. II., p. 22.

curious iodid were examined by me at the request of a New York chemical manufacturing firm and I found that the yellow color was that proper to protiodid, and that the green powder under the microscope plainly revealed that it was composed of metallic mercury globules and the red biniod with some yellow protiodid. By recombination $(\text{HgI})_2 = \text{Hg} + \text{HgI}_2 + \text{HgI}$. The yellow iodid in the stomach heat could easily undergo this reduction and reintegration, but the acid stomach fluid and duodenal juices would separate the iodine and afford yellow oxid, and finally metal. If the mercurous iodid passed the pylorus unchanged it would more closely resemble calomel in its effects by resolution into black oxid and mercury and finally wholly into mercury. Schläpke says,¹⁷ explaining an interesting point in this connection: "It has been frequently observed that the external application of calomel may give rise to severe inflammation of the conjunctiva, if used simultaneously with the administration of iodid of potassium internally." This, Dr. Schläpke explains by the formation of mercury iodate and iodid, which in the presence of common salt or iodid of potassium are soluble and act as caustics. He finds that if potassium iodid be taken twice daily, in half-grain doses, its presence can constantly be detected in the conjunctival sac. Dr. Plym. S. Hayes¹⁸ detected metallic mercury in the urine of a patient who had been taking this salt. The patient developed renal symptoms which disappeared on the discontinuance of the mercury iodid, and were therefore regarded by Dr. Hayes as due to its causing emboli in the way previously described. An excessive dose reaching the kidneys unreduced would encounter urea enough to decompose more of the drug; the precipitate would thus occlude the uriferous tubules and account for the congestion.

Red Iodid of Mercury.—The biniodid loses its iodine in the pancreatic fluid, though a small amount of the combination may pass into the circulation, there to be decomposed by the alkaline blood. It resembles the bichlorid in responding to reagents, and is as poisonous, another indication that the mercuric combination owes its activity as much to the amount of the radical liberated in decomposition as to anything else. Topically the effects of concentrated iodine are obtained with mercurialization precisely as a similar application of the bichlorid exhibits the localized influence of liberated chlorine.

Ammoniated Mercury.—Hydrargyrum ammoniatum is prepared from the bichlorid, and to all intents remains corrosive sublimate, combined with ammonia. Its insolubility renders it ineligible for internal use. Pancreatic fluid acts upon it as upon bichlorid.

Mercury with Chalk.—Hydrargyrum cum creta is milder than blue mass. It does not contain the same percentage of metal, and the chalk does not maintain separation of the globules, which often are visible to the unaided eye. The metal in all the chalk mixtures examined was in larger spheres than in blue mass, hence the latter is much the better preparation.

The Oxids of Mercury.—The red oxid, as prepared by the pharmacopœial formula, contains mercury nitrate, and complete purification of the oxid thus made can not be accomplished without endangering the compound. In consequence it differs from the yellow oxid, though said to be an allotropic deutoxid, by its harshness and crystallization, the yellow being

amorphous and much milder; but as it contains twice as much oxygen as the black oxid, just as there is twice as much chlorine in the bichlorid, the yellow oxid would, in obedience to this general rule, be expected to act more vigorously than the black oxid. The latter has been given in pill form in place of blue mass or calomel, according to Wood¹⁹ and found to have identical effects. Dr. Christison²⁰ advises the use of black oxid ointment in place of officinal mercurial ointment.

Turpeth Mineral.—There has been much discussion over the chemie and physiologic properties of this preparation. After analyzing the contradictory statements of all accessible authors, I am justified in calling it a mixture of mercuric oxid and mercury sulphate, $\text{HgO} + \text{HgSO}_4$. It is an emetic like other metallic sulphates, and responds to all tests for the sulphate and oxid of mercury.

Ethiops Mineral.—According to the method of its preparation this substance is a mixture of sulphur and mercury uncombined, cinnabar and metallic mercury with sulphur, and sometimes a mercury sulphate.

Cinnabar.—Mercuric or red sulphid differs from the other mercuric preparations by being insoluble and undecomposed by alkaline solutions, consequently most of the dose will pass unchanged from the system, though some mercury must be liberated, for it acts rapidly as a mercurial. When used by fumigation, it liberates sulphurous acid gas and mercurial vapor. "In its native state there is reason to believe it has no action at all."²¹ It may thus be regarded as inert, owing to its insolubility. Anything apparently inconsistent with this view may be accounted for by presuming that other forms of mercury accompany the dose as impurities. If any authentic record could be found indicating how long the Japanese had used cinnabar and other crude mercurial minerals it would throw light on the history of syphilis.

Oleate of Mercury.—With a vague, ill-defined idea that all mercurials depend for their efficacy upon their conversion into an oxid in the body, Dr. Marshall suggested, in 1872, the incorporation of mercuric oxid with oleic acid as an eligible substitute for the common ointment. Any chemist can see that in Marshall's process, or even later improvements in modes of manufacture of this preparation, the oxid must be destroyed. In fact, a precipitation of visible metal occurs, the weight of which is subtracted, plus its oxygen weight, from the original weight of the mercuric oxid used, and the invisible remainder is assumed to be mercuric oxid in oleic acid. Squibb's label on the oleate bottles reads: "This bottle contains—per cent. of mercuric oxid in oleic acid." By decanting off the liquid, further precipitation of the metal, as metal, can be found, and under the microscope beautifully uniform and minute globules of metallic mercury in countless numbers may be seen suspended in the oleic acid. A mechanical mixture of oleic acid and minutely divided mercury presented very nearly the same appearance, the globules wanting in uniformity, which can be remedied by permitting the mixture to stand some days, allowing the larger globules to precipitate. This settling may prove to be the cause of the minuteness and uniformity of size in Squibb's oleate. So, instead of a mercuric oxid being introduced into the system by innunction with this preparation, a simple mercurial.

²¹ National Dispensatory, p. 791.

reduced to such beforehand, is thus administered, and so acts. A Chicago physician applied the oleate several times to his axillæ, and soon after, on being dry-cupped, called the attention of Dr. J. S. Jewell (who was treating him for ataxia) to the presence of mercury globules visible in the cupping-glass. Prior to 1890 the yellow oxid of mercury was incorporated with oleic acid at a temperature of 74 degrees C. (165.2 degrees F.) which promptly reduced the oxid into metal. The later adoption of 40 degrees C. (104 degrees F.) merely delays the eventual reduction of the oxid. After I announced the instability of the oleate of mercury,²² Squibb²³ noted the tendency of his oleates to deposit mercury, and offered the 20 per cent. strength only as more stable than those containing less quantities of metal. Nevertheless at the present day the oleate still has its "looking-glass" deposit on the bottom of the bottles, and when the "oleate" is microscopically examined the metallic globules will be found slowly floating downward or suspended in the oleic acid. The oleate is *not* a yellow oxid but is rather a finer unguent of the metal.

The *Bibromid* resembles corrosive sublimate in most respects, and the bromid calomel. Donovan's solution contains the deutoxid, and completes all the medical compounds. All seem to be reduced directly or indirectly to the metallic state. As the therapeutic differences of mercury preparations are ascribable mainly to the differences in sizes of the globules, an intermediate effect might be expected between the mercurous and mercuric doses, should the extremely divided black precipitated mercury from stannous chlorid and corrosive sublimate be used.

The preparations of mercury may be divided into:

1. Simple mercurials which contain metallic mercury in a finely divided state and which act mechanically in the system.

2. Mercurous compounds which decompose first into the black oxid of mercury and then into metallic globules of about the same size as those in the simple mercurials, only the sizes are more uniform.

3. Mercuric compounds which decompose into the yellow oxid and then into much finer globules of mercury than are yielded by reduction from the mercurous salts. Mercuric cyanid passing more directly into the metallic state by the action of intestinal sugar.

4. Sulphur and nitrogen compounds not generally used as medicines.

The proportions of excipient and metal in the simple mercurials are easily estimated. By calculations based upon the combining weights of the mercurous or black oxid group one grain of metallic mercury is yielded by the reduction of the following weights of the compounds: Black oxid 1.04, calomel 1.175, yellow iodid 1.635, bromid 1.40 grains. The mercuric or yellow oxid group contains one grain of metallic mercury in the following proportions of the different compounds: Yellow oxid 1.08, corrosive sublimate 1.855, red iodid 2.77, cyanid 1.77, bibromid 1.80 grains. Essentially, all the mercurous salts act alike medicinally and are closely allied in their effects to the simple mercurials, but calomel will always hold its position as the most preferable of mercurous salts because it contains the largest percentage of base with the exception of the black oxid, which would take the place of calomel were it not for the instability of the oxid. All the salts of the mercuric

group, to which corrosive sublimate belongs, are based upon and decompose with alkalies into the yellow oxid of mercury, a dense amorphous powder, which further breaks up into extremely minute globules of metal in light, heat or deoxidizing agents such as sugar. These globules are, as a rule, incomparably smaller and more numerous than those obtained from the mercurous compounds. Micrometrically they number one hundred million to six hundred million globules to the grain. A dose of one-tenth of a grain of the bichlorid of mercury will contain, when decomposed by intestinal fluids, ten to sixty million globules. By spreading the solution over a square decimeter of surface, and precipitating with caustic potash solution, this area will show under the microscope a yellow powder. Glucose at the body temperature will cause these oxid particles to break into black points, which under high magnifying powers become apparent as mercury globules in the numbers mentioned.

The so-called "*Red Oxid of Mercury*" needs special reinvestigation, and I feel certain that sooner or later chemists will acknowledge it to be a nitrate, and that is not an oxid. In 1771 Priestley disengaged oxygen from potassium nitrate and three years later from a mercuric compound which he assumed to be an oxid because focused sun rays liberated therefrom a gas which supported combustion. Had nitrogen accompanied the disengagement of oxygen the result would have been the same, for nitrous oxid will also support combustion by parting with its oxygen which combines with the carbon and hydrogen of the candle, heat effecting the interchange. Nitrous fumes are given off by heating a mercuric nitrate. In processes for the conversion of the nitrate into the red oxid especial care is taken that nitrogen is included. Pharmacists have been vexed and puzzled over the reasons for some processes which afford promptly the characteristic red oxid crystals which at other times gave the yellow oxid only. Careful examination of chemical writings will show that whenever the yellow oxid is precipitated from a soluble salt it has been by a process which will exclude nitrogen and that whenever the so-called red oxid is formed nitrogen is included even if it abstracts it from the air direct (in spite of the assumed inertia of atmospheric nitrogen), or its free ammonia, as when the yellow oxid cools in the test tube and becomes red. The yellow is amorphous and is physiologically milder, and prepared in the absence of nitrogen. The red is crystalline and is harsh in its action when taken internally, and it can not be made when nitrogen is excluded. It is a mere assumption that the red is an allotropic form, and there are better reasons for believing it to be an insoluble subnitrate belonging to the great list of nitrates which mercury is more capable of forming than any other metal.

The mechanical color changes of mercuric iodid are not comparable to the differences between the red and yellow oxid tints, depending upon chemical associations. The U. S. Dispensatory acknowledges that complete purification of the oxid from the nitric acid can not be effected without endangering the compound. The British pharmacopeia calls it nitric-oxidum in recognition of the derivation and probable dependence upon nitric acid for its characteristics.

The following tables will enable comparisons of the wide dissimilarity between the two compounds:

²² Western Druggist, 1881.

²³ Semi-annual price list, No. 51, 1881, p. 15.

YELLOW OXID.

Prepared by precipitating mercuric solution with KHO. Forms yellow amorphous powder. When prepared in any way nitrogen capable of combining is excluded.

Has been proven to be an oxid.

Mercury forms only two oxids, the black and the yellow.

Combines readily.

Forms mercuric oxalate with cold solution of oxalic acid.

Readily forms oxychlorid with HgCl_2 solution.

Boiled with potassic bichromate it yields basic mercuric chromate $\text{HgCrO}_4 \cdot 2\text{HgO}$.

Does not blacken on heating.

Nitrogen in some form is required to convert it into the red oxid.

Its physiologic action is mild and not escharotic.

RED OXID.

Prepared by heating nitrate of mercury until red fumes cease. Forms red crystals. When otherwise prepared, as in air, forms with difficulty, owing to nitrogen not readily combining, but nitrogen is never excluded.

Has not been proven to be an oxid nor has it been found apart from nitrogen and responds to tests for sub-nitrate.

Mercury forms more nitrates than any other metal and unknown nitrates exist.

Combines with difficulty.

Does not form oxalate.

This change is very slow.

Similarly treated forms basic salt with large proportion of base $\text{HgCrO}_4 \cdot 3\text{HgO}$ (Millon.)

Blackens on heating (assuming the color of mercurous oxid).

Neutralizing its acid solutions precipitates the yellow oxid, thus abstracting nitrogen.

Its physiologic action is harsh, irritating and escharotic, and like other metallic nitrates.

The Toxicology of Mercury.—Where hydrargyria had been induced let us assume that in three months exposure to mercury fumes at the rate of a gram per day (which in quicksilver works can be considered a very moderate figure), and allowing one-half of this to have been excreted, there would remain forty-five grams of mercury lurking in the vessels, bones, viscera, muscles, etc., capable of division into thirty-three hundred and seventy-five million particles. Distributing these about the body by probabilities we can estimate three hundred million concerned in producing ptialism through the parotid, submaxillary and sublingual glands and branches of the internal maxillary artery, with a portion (say a million) bearing directly upon the cerebro-spinal centers through the carotid and basilar arteries. The condensation of any thousand of these globules in certain areas would be enough to produce nervous effects from chorea to paralysis.

Naunyn²⁴ says that living flowers serve as the most delicate reagents for detecting such dangerous impurities in the air, they die very rapidly in an atmosphere containing mercury. A gold leaf becomes rapidly coated in such exposure, and wood painted with flowers of sulphur becomes brown on the surface, owing to sulphid of mercury formation. It is not possible for a plant to live with its cellular interspaces, through which pass nutrient fluids and gases, clogged up with multitudinous particles of metal, and this is the exact condition of the poisoned plant under microscopic examination. Parasites with small tubular structures such as respiratory tracheæ are actually suffocated by these little bullets lodging in

these passages. I demonstrated that mercurial ointment killed bed bugs by occlusion of the spiracles, tracheæ and alimentary canal, a condition readily determinable by low magnifying powers.

All quadrupeds whose heads are frequently below the level of the spinal column would be most liable to have mercury accumulations in the vessels of the brain and cranium when poisoned by mercury, and Taylor²⁵ observes that "ruminants are easily killed by mercury ointment; their lungs are congested and head drops to the ground." That the mercuric salts are reduced to the metallic state is shown also by their elimination as metal in urine, feces, bile and sweat. The yellow oxid and a carbamid are precipitated from soluble salts of mercury in urine. The filtrate throwing down no precipitate with caustic potash shows that all the mercuric salt is decomposed. An excessive dose reaching the kidneys would encounter urea enough to reduce more of the poison which would occlude the uriniferous tubules and account for the congestion and transient albuminuria.

RECAPITULATION.

1.—Mercury acts mechanically as a deobstruent upon the glands and lesser tubular strictures, by virtue of its unstable chemic properties, its volatility and great weight.

2.—Its condition in the fluids and tissues is that of finely divided globules of the metal numbering upward of one thousand million (one billion, French) to the cubic centimeter, and as a vapor of the metal. In whatsoever form it may be taken, it is quickly precipitated as mercury, and without change is excreted or retained in the system, mainly in the bones.

3.—It cleanses the intimate visceral tissues by projecting from them materials of less weight, and in this way breaks up, removes or prevents morbid accumulations. In excess it occludes the tubular parts, and may produce any of the phenomena attending stasis of vital operation anywhere about the body, such as ulceration, congestion, paralysis, anemia, etc.

4.—The liver and inferior maxillary region for anatomic, and the former for physiologic, reasons receive most of its primary influences.

5.—It can be given in larger doses in warm weather or climates, because heat favors its elimination, systemic effects decreasing necessarily in proportion.

6.—Its antiphlogistic properties are merely deobstruent and detergent.

7.—Its value in syphilis is owing to its acting in the line of least resistance, breaking up any nidus the disease may form. The ability of the metal to envelop and carry microorganisms gives it an ameboid or phagocytic value. In phagedenic ulcerative processes it would be contraindicated, because the degeneration is too rapid to be effectually reached by mercury, which is not the case in slower-forming specific ulcerative stages. Its administration in these diseases could be regulated by the rapidity of degradative processes. Comparatively slowly acting morbid centers, or those of a congested nature, could be improved by mercury where the drug would only accelerate rapid tissue destruction.

8.—It is tonic, by increasing red blood globules whose formation has been prevented by glandular perversion, the metal removing the obstructions toward their formation, while in overdoses anemia is produced by occluding the vessels it, in small doses, cleanses.

²⁴ Ziemssen, p. 618.

²⁵ On Poisons, p. 353.

9.—The solubility and consequently superior penetrability of the bichlorid is probably productive of the mercurial characteristic effects which seem out of proportion to the amount of metal in doses of this salt; but it is not to be denied that chemic or direct neurotic influences coöperate with the metal in the more active preparations, and thus possess features of their own.

10.—Experimental evidence is opposed to probable formation of any compound in the body, and supports the belief that decomposition invariably and almost instantaneously follows its ingestion with the precipitation of mercury as minutely divided globules, from any preparation of which it forms the base.

PUERPERAL ECLAMPSIA AND ITS TREATMENT.

Read before the Marion County (Ind.) Medical Society.

BY J. T. McSHANE, M.D.

INDIANAPOLIS, IND.

In presenting this paper, with the reports of the cases which have come under the writer's observation, together with the treatment and results, it would be ingratitude not to mention the name of the late Dr. Ellerslie Wallace, of Jefferson Medical College, Philadelphia, who, after a large experience, taught with emphasis the value of venesection in puerperal eclampsia. His hand with which he emphasized his words, with a deformed index finger, the result of a dissecting wound, was not more apparent to me when he said relative to this subject "you are on a life saving mission: do your duty fearlessly, and bleed for effect, not for ounces of blood," than when at the bedside of my first patient with eclampsia. It occurred in 1871 in the case of Mrs. W., primigravida, aged 35 years. Labor was slow and a severe headache was complained of which did not yield to free administration of bromid of potassium. After four hours of moderately hard labor the patient complained of intense throbbing pain in the head, sudden fright and blindness, followed almost immediately by a violent convulsion. As soon as the convulsion subsided, preparations were made for venesection, but before it could be done a second convulsion came on. Without further delay the arm was constricted and a large stream of blood allowed to flow. A third convulsion came on while the blood was flowing. After this convulsion passed off the patient's face, which had been dark, swollen and distorted, became pale and placid, the pulse became weak and thready. The bandage was removed from the arm and the flow stopped. The os uteri was pretty well dilated and with the assistance of Dr. S. C. Dove, of Westfield, Ind., whose office was less than a mile away, the patient was delivered of twins, both of which were still. A good recovery followed.

Mrs. G., now of this city, had convulsions with two confinements, and also early in a subsequent pregnancy. Dr. Rodman, of Zionsville, now of Denver, saw her during her first attack. She had some fifteen convulsions before bleeding, none after, and two hours later she was delivered of a masecrated child. In her second attack Dr. N. G. Harold, of Carmel, Ind., saw her with me. She had had seven or eight convulsions before my arrival. She was large and plethoric and an unusual amount of blood was required to produce the desired effect. Labor advanced slowly and in about two hours she was again seized with a convul-

sion. The vein in the opposite arm was opened after which there was no more trouble, and as soon as dilatation was sufficient to admit of the application of the forceps she was delivered of a still child. When six months advanced in a subsequent pregnancy this patient had violent throbbing headache, a slight convulsion, clouded memory and intellect, all of which were immediately relieved by venesection. This treatment was repeated twice for the same symptoms, with the same happy results, before her term expired, when she was delivered of a healthy child, having no return of convulsions.

Mrs. W., lived at Nora, Ind., now of this city. She was delivered in her first confinement of a healthy child without unusual labor or other symptoms. Some two hours later she was seized with convulsions which were terrific in violence and came in quick succession. She had eighteen or nineteen convulsions, some of which were observed by Dr T. M. Hinshaw, who now lives in Westfield, Ind. On my arrival the doctor and the husband considered the case hopeless, and, indeed, it looked as if their opinion was correct. The patient was profoundly comatose, face almost black, swollen and distorted, leaving no trace of its former likeness, pulse quick and wiry, temperature high. As soon as the convulsion passed off a vein was opened and a large stream of blood allowed to flow. The amount drawn, though large, was disregarded, but the effects were eagerly watched. The face blanched, the pulse became thready and soft; the bandage was loosened. No more convulsions followed. The patient returning to semi-consciousness the next day heard her baby cry and exclaimed, "Whose baby is that?" Her recovery was not retarded. Her memory was thoroughly obliterated for a period of two days before and four days after delivery.

Mrs. S., multipara; a patient of Dr. W. O. Harland, now of Chicago. This patient was neither anemic nor plethoric. Soon after delivery she was seized with violent convulsions. She had taken chloral and chloroform without effect, and had had six or eight convulsions before my arrival. After a moderate bleeding convulsions subsided for a time. After an interval of two or three hours' rest, convulsions returned. Her pulse was hard and quick and the temperature was high. Blood was again drawn but in larger quantities, leading Dr. Harland to think the danger point was reached. In a letter received from Dr. Harland a few days ago, in answer to inquiry concerning this and another case, he says "we stopped the convulsions in Mrs. S., but we had to bleed her nearly to death to do it." The danger was more apparent than real. She had no more convulsions and was up and well in the usual time. A subsequent pregnancy was attended with a throbbing headache, disturbed vision, congested face and clouded memory, at the sixth month. A vein was opened and while the stream still flowed the grateful patient exclaimed "Oh, what a relief!" These symptoms reappeared at the seventh and eighth months, and the patient sought relief by the lancet both times. The delivery of a healthy child at term was normal.

Miss P., primigravida, also a patient of Dr. W. O. Harland. Convulsions came on early in her labor. She was freely bled after she had had five or six convulsions. The intervals were lengthened, but an occasional convulsion came on until the os was sufficiently dilated to admit the application of forceps. She was

delivered of a still child, after which she had no more convulsions. She made a good recovery.

Miss H., primigravida. Large, strong, domestic; walked four miles to the house of an acquaintance. She was dazed and unable to give an account of her visit or from whence she came. In a short time she was seized with a convulsion. My arrival was delayed some hours on account of the messenger bearing no intelligence regarding the nature of the case. On my arrival five hours after the first convulsion she was comatose; her tongue was lacerated and bleeding. The family in whose house she was had no knowledge of her labor nor her pregnant state. An examination revealed both, the os being considerably dilated. Her convulsions had been frequent and severe, according to her great muscular development. After venesection she had no more convulsions. She shrank from her pains, and being unconscious the assistance of two strong men of the neighborhood was required to hold her in position in the bed. In about two hours, dilatation was sufficient to admit of the application of forceps, when she was delivered of a large still child. The return of consciousness was deferred thirty hours after delivery.

Mrs. D., multipara, was attended in her labor by Dr. Leavens. She complained of blinding, throbbing headache during the progress of her labor. This was lightly regarded, the physician thinking it would subside after delivery. Labor terminated at 4 o'clock P.M. At 2 o'clock the following morning a summons reached me. She was in a convulsion when the messenger started, and was in a stupid state on my arrival. A vein was opened and about a pint of blood taken when, the patient expressing a feeling of relief, the bandage was removed. Thirty minutes later she was attacked by a second convulsion. The vein in the opposite arm was opened and the blood allowed to flow until the face became pallid. The patient being large and plethoric a large quantity of blood was required. No further trouble followed and the patient's recovery was not retarded by the loss of blood.

Mrs. K., of Mattsville, Ind., was seized with a convulsion during her third confinement. The premonitory symptoms were pronounced and a vein was opened just as a convulsion came on. A healthy child was delivered an hour later and her recovery was uneventful.

Mrs. S., primigravida, was attacked with convulsions while under the care of Dr. K. C. Hershey, who then lived at Mattsville, Ind. The convulsions were hard and came in rapid succession. She had a large but uncounted number before my arrival. Her pains had been constant, severe and distressing, but not of an expulsive character. Free bleeding resulted in temporary relief. Examination revealed dilatation to the size of a silver half dollar, and the os presenting high up against the sacrum, the result of obliquity of the uterus. Gentle pressure against the fundus and slight traction with the finger brought the os down to its proper position, when the labor pains became strong and normal, with intervals of rest. Consciousness returned so that the patient conversed intelligently. After waiting three hours the patient was left in the care of Dr. Hershey, the attending physician. After some time had elapsed he was called away from the bedside. The history of the case shows that the pains lost their distinct character, becoming constant and distressing. After four hours intermission the convulsions reappeared. On my arrival in

answer to a second summons the patient was in a moribund condition and soon expired. At the request of the husband and with the assistance of Dr. Hershey, the child was removed by Cesarean section. It was a perfect child, but as we expected, after so many convulsions, it was still.

Mrs. C., large, fleshy patient in fourth confinement. Had complained of throbbing headache for two days. A hurried messenger came with the report that she had fallen on the floor and they thought she was dying. Her term had expired and an examination revealed a dilated os, although no uterine pains had been complained of. She was in her fourth convulsion on my arrival. Her mouth was bleeding from laceration of the tongue. A vein was opened and a stream allowed to flow until the dark congested condition of her face gave place to pallor. Two hours later a still child was delivered and she made a good recovery.

Mrs. S., now living in Kansas; during her first confinement was seized with a terrific convulsion. This was in all respects like a puerperal convulsion, but the patient having occasionally had epileptic symptoms, this was at first thought probably of that character. Chloral hydrate and bromid of potassium were freely given but in less than an hour a second convulsion came on which was followed by stupor and continued congestion of the face. My conclusion was that, although a slight epileptiform manifestation had been observed once or twice a year, this was puerperal, and fearing death of the child and danger to the life of the mother if the convulsions were repeated, she was bled until the desired effects were produced. No more trouble followed and she was soon delivered of a healthy child. It is a matter of regret that examinations of the urine were not made in each case reported. In the four cases in which analyses were made, there were traces of albumin in two. Those who have had the misfortune to witness cases of puerperal eclampsia will readily appreciate the delay which would attend such examination before treatment. The patient and child are in great danger and the necessity for prompt action engages the physician's time and attention. Whether there is or is not albuminuria, although of scientific interest, is at the instant of little importance. The treatment which relieves in the one case also relieves in the other.

The etiology of puerperal eclampsia is not definitely settled. Perhaps Löchlein covers the ground by stating that "no explanation of eclampsia has been fully established, and the disease has certainly more than one cause." Albuminuria is present in a majority of the cases, but this is not sufficient to afford a positive decision that the condition of the kidneys which produces albuminuria is the cause of eclampsia. Albuminuria is said to be present in five cases of pregnancy to one of eclampsia. It is pretty generally conceded that, whether the case is one of eclampsia gravidarum, parturientium or puerperarum, the arterial pressure is high, and this is true whether the blood is rich in red corpuscles or not. This condition may depend upon the action of the vasomotor system, or to increased volume of the circulatory medium, or both. The kidneys become clogged by congestion resulting from high tension, and their function is partially suspended, in which case albuminuria may or may not be present. Women in pregnancy are much inclined to accumulate flesh and when constructive metabolism is in excess of destructive meta-

bolism, toxemia and plethora are simultaneously present. When albuminuria is present, unless chronic, the patient recovers without delay after cessation of convulsions, when the pressure is removed allowing the kidneys to assume their normal state. As a rule, the condition of the patient who is to become an eclamptic is not incompatible with comfortable health; the foudroyant out-break being the first announcement of departure from the physiologic state.

Reflex uterine irritation is said to be a cause of eclampsia in some cases. The fatal case of Mrs. S. reported above, is probably one of this class. Obliquity of the uterus disturbed the normal expulsive character of the pains. When the uterus was righted the constant grinding, distressing pains ceased, giving place to normal labor. When left without support obliquity again took place, with disturbance of normal labor pains, and reappearance of convulsions. While in this case the obliquity seemed to be a disturbing factor, it is well known that such obliquity not infrequently exists without such disturbance. It would seem to be an interesting and curious fact that mal-presentations are very rarely attended with convulsions. The cases reported in this paper were all vertex presentations with the face to the right or left sacro-iliac synchondrosis. Dr. King asserts that convulsions scarcely ever occur in cross or shoulder presentations. A Dublin obstetrician says (*Dublin Journal Medical Sciences*) that there is little fear of eclampsia if the child does not present by the head. This refers to eclampsia during labor; certainly not to cases occurring months before. There are exceptions to this rule. In a series of fifty-nine cases reported by Ramsbotham there were four breech presentations.

The annual of the *Universal Medical Sciences* for 1895, records the researches of Rapin and Monier, who examined the blood of four women with eclampsia, and in three of the cases found a special bacillus, which they were able to cultivate, and when inoculated into animals caused symptoms of eclampsia.

Chamberland has experimentally proved that some poisonous element is present in the blood of eclamptic women, but the exact nature of the poison, or its origin, have not been determined. A rabbit is killed by the injection into its tissues of healthy human serum, when injected in the proportion of ten grams of the serum to every kilogram that the rabbit weighs. Chamberland has experimented extensively with the blood of eclamptic women, and has found the amount of serum of such blood necessary to kill a rabbit is less than the serum from a healthy person. In some cases one-half, and in others less than one-third the proportionate amount is sufficient to prove fatal.

It is believed by some investigators that the liver may have something to do with some of the cases of puerperal eclampsia. The healthy liver modifies certain poisonous elements brought to it from the intestines through the portal vein, and impairment of the liver which would wholly or in part, destroy or suspend this function would admit to the blood substances freighted with toxic properties. Hahn, Masser and others have shown by experiments, by which the blood from the portal vein is emptied directly into the circulation, thereby depriving it of passage through the liver, nervous symptoms similar to those of eclampsia are produced. This is especially pronounced when the experiment is made after the inges-

tion of meat. Their deduction is that these symptoms are due to the presence of carbamic acid in the blood, a substance which in passage through the liver is converted into urea. Further experiments show that when carbamic acid is introduced into the circulation not only the nervous symptoms are developed but the urine becomes scanty and albuminous.

Women in their first pregnancies, and also those who have more than one child in utero are most susceptible to eclampsia. Of the fourteen cases reported in this paper six were in cases of primipara, one of which had twins. In reference to the frequency of convulsions statistics are variable. The total number of deaths from eclampsia reported to the Board of Health in New York city in the nine years ending in 1875, were 408. The estimated maximum number of deliveries during that period was 284,000, or nearly one death in 700 confinements.

The vital statistics furnished by the Indiana State Board of Health show the number of children delivered during twelve years and nine months to be 452,429. Deducting one birth from each case of doubtlets and two from each case of triplets the approximate number of labors represented in these reports is 449,000. The number of deaths reported from eclampsia during this period is 440 or one in 1,020 deliveries. One series of 100,935 deliveries in the Philadelphia Board of Health reports, shows 94 deaths from eclampsia, or one in 1,073 confinements. Of women attacked Hecker found 1 in 522; Wiegner 1 in 519; Kleinwächler and Galabin 1 in 500; Korman 1 in 600; Corson 1 in 300; Cazeaux 1 in 200 deliveries. It is estimated by some authors that the average is 1 in 500 labors. The health reports show the deaths only, but if this average is correct about 50 per cent. of the patients die. Parvin places the percentage of women attacked at 1 in 250 or 1 in 300 in this country, and if this is correct the death rate from this cause as compared to the number of patients affected is reduced to about 28 to 30 per cent. Dr. Kemper, of Muncie, had nine cases of eclampsia in his one thousand labors reported. Eight of the women recovered and one died. After reference to the great fatality which attended eclampsia in the seventeenth and eighteenth centuries, Ramsbotham says in his work on obstetrics, "few cases now terminate unfortunately; and the favorable results are to be attributed to the extent to which bleeding and other evacuant means are carried."

Patients who are bled in this disease do not suffer from anemia on account of the depletion, but regain their normal strength and color, and as a rule, are out of bed as early as though nothing unusual had transpired. Prof. Fordyce Barker insisted upon the unmistakable clinical evidence favorable to the employment of the lancet, and pleaded for its restoration in the management of puerperal eclampsia. Lusk says the claims of bleeding in eclampsia rest upon a substantial foundation, and that its special advantage lies in its prompt action.

Speigleberg says, "No means so quickly lessens arterial pressure, none so quickly restores their function to the kidneys, irritable from blood pressure, and few act so readily upon the excited vasomotor nerves, causing relaxation."

Patients with eclampsia are never able to sit while the operation is made, consequently a larger quantity of blood is required to produce the desired results than if the sitting posture could be assumed. It is

much better not to bleed at all than to bleed inefficiently. While the loss of a small amount of blood will do no harm it can do no good, and therefore it brings probably the very best life-saving remedy in eclampsia into disfavor and disrepute.

The life of the child in eclampsia parturientium is endangered by each succeeding attack, rarely persisting after the fourth or fifth convulsion. In proportion to its relative prompt action the life of the child and also that of the mother are enhanced by venesection. In claiming for the lancet a clean, safe, prompt, efficient and ever at hand remedy, the value of other remedies is not ignored. Dr. L. J. Hammond, Secretary of the Staff of Maternity Hospital, of Philadelphia, has kindly furnished me a history of nine cases which occurred in that institution during the last five years. All but one occurred in primigravida, and three women died. The treatment relied upon is depletion by purgation; chloral and bromids per rectum, veratrum viride, hot packs and anesthetics during the seizure, oleum tiglii is the cathartic relied upon. Two of the cases which recovered were bled, one to the amount of twenty-six ounces.

In answer to a letter addressed to the Philadelphia Lying-in Charity and Nurse School, Drs. W. Reynolds Wilson and Della M. S. Walker kindly prepared for me a table of the nine cases which occurred in that institution during the last four years. Previous history was negative in all the cases but two, one of which had vomiting of pregnancy, and the other had previous dropsy. These two patients died, the other seven recovered. One of the patients that recovered had sixteen, one had ten, one had three, and three had two convulsions. One of the patients who died had one, and in the other the word "frequent" takes the place, in the column, of the figure designating the number. The patient who had sixteen convulsions was bled. The others were treated by chloral, morphia and calomel. One exclusively by purgation, except that chloroform was used in all for the paroxysms. The average number of convulsions in these cases is small, owing doubtless, to the fact that the patients were in the hospital under the immediate attention of the physicians who were equipped with everything needful, thus securing prompt relief before the patients became so profoundly influenced. Whether the poison contained in the blood of an eclamptic acts directly upon the cortical cells of the brain is not demonstrable. It is a reasonable position to assume that it does, and that this poison, as well as reflex irritation from abnormally painful uterine contractions, disturb the cell power to control energy. The result is sudden liberation of energy manifested in a convulsive seizure.

Chloroform, chloral and morphia lessen reflex irritability and paralyze cell energy, thereby aiding in holding convulsions in abeyance; while diaphoresis, purgation and venesection relieve arterial tension and eliminate the poison.

The high arterial pressure which is almost universally present in eclampsia has lead many practitioners to believe that this disease does not occur in patients who do not bear depletion. Morphia, chloral and chloroform have been used with excellent results in a large number of cases. These agents may be used with advantage after depletion, or in the early history of an attack. After a patient has had a large number of convulsions and is in a state of coma, or near it, the administration of such drugs is not likely to prove

beneficial. Chloroform has been recommended and given in full anesthetic doses for the purpose of completely paralyzing the motor centers. There is much danger from prolonged anesthesia carried to the surgical degree, and added to coma, or tending coma, resulting from convulsions, it is capable of doing irreparable harm. The same may be said of large doses of morphia and chloral.

Dr. W. Reynolds Wilson, in his article on "The Use of Morphia in Eclampsia, with a Report of Two Cases," published in "The Annals of Gynecology and Pediatrics," June 1892, a reprint of which the author has kindly furnished me, discusses this subject pretty thoroughly. In the second case reported by Dr. Wilson, morphia was given hypodermically in doses ranging from $\frac{1}{8}$ to $\frac{1}{2}$ grain. The history of the case shows the drug had a partially controlling influence, but "the patient was bled on account of vascular tension, shown in the congestion of the face, and throbbing of the arteries." Fifteen ounces were abstracted after which the patient had no more convulsions, but the morphia was continued and served a good purpose in controlling the restlessness.

Veratrum viride has been successfully employed in some cases reported. In large doses it slows the pulse, and as expressed by Hare, it "bleeds the patient into his own vessels" by filling up the mesenteric veins and thereby relieving arterial pressure. Dr. Fearn, of Brooklyn, in his article published in the *American Journal of Obstetrics* on "Veratrum Viride in Large Doses as a Substitute for Blood-Letting in Puerperal Eclampsia" recommended the tincture of veratrum viride in doses ranging from fifteen minims to a teaspoonful repeated every five or ten minutes until the pulse became soft or vomiting occurred. After the arrest of convulsions he recommended the continuation of the drug for some hours in smaller doses and at longer intervals keeping the pulse below fifty per minute. In each case reported in this paper a very large dose of some active cathartic was given. Nitrite of amyl was used by Dr. W. F. Jenks, of Philadelphia, on the suggestion of S. Weir Mitchell. Ether had been used without avail. The inhalation of a few drops of nitrite of amyl immediately arrested the convulsions, but the patient had a dangerous uterine hemorrhage, which was attributed by Dr. Jenks to the action of the drug. The opinion of Dr. Jenks is corroborated by the experience of Dr. A. W. Brayton, of this city, who met with a dangerous uterine hemorrhage following the administration of one-fiftieth grain of nitro-glycerin, the action of which is similar to that of nitrite of amyl. The drug was given as a cardiac stimulant in a case of palpitation of the heart in a woman who had been delivered six days before.

Delivery should be facilitated in cases of eclampsia parturientium, when labor is difficult, and where the os uteri is dilated, by the application of forceps, or podalic version. Dilation may be hurried by the use of the colpuruter. A method has been proposed and practiced by Dührssen of Berlin which in his hands seems to have proved highly satisfactory. When the cervical canal is opened up, and the obstacle to delivery is the undilated os externum he makes four incisions reaching from the margin of the os up to the utero-vaginal junction. This he claims leaves no further obstacles to the delivery of the child, which can readily be effected without any fear of tearing the soft tissues. Thirty-five cases were treated by him, by this method, according to his published report, with-

out the loss of a mother, and with a loss of only two children. The technique of this operation is explicitly stated in his report.

There is great danger to the life of the unborn child in cases of eclampsia. Its death not unfrequently occurs during the first convulsion, often during the second, and after a number of convulsions the child is rarely born alive. The child is profoundly influenced and if its life is spared until birth it may die in convulsions soon after, as was the case with two of the cases reported by Drs. Wilson and Walker, of Philadelphia, and a case reported by Spence which was removed alive by the Cæsarean section, the mother having died from eclampsia before there was any disposition to labor. Respiration is suspended during the early part of an eclamptic seizure, and is very imperfect until the attack passes entirely off, thus adding to the already bad condition of the maternal blood, rendering it inadequate to act as an oxidizing and purifying agent for the infantile circulation through the placenta. It is therefore fair to say Dührssen's cases must have been selected and operated upon immediately after the onset of the convulsions, otherwise more than two still births would have occurred in thirty-five labors. This is a possible illustration of the effect which over-enthusiasm has on statistics.

TRAUMATIC CARIES OF CERVICAL VERTEBRÆ.

A CASE WITH REPORT OF THE POST-MORTEM.

BY L. G. NORTH, M.D.

TECUMSEH, MICH.

Mr. R. J., aged 34 years, unmarried, an Englishman by birth and a resident of this country for fourteen years. By occupation a farm laborer and ditcher. In build very muscular, and rather thick set. He had great endurance, taking pride in the amount of work he could do in a day. His habits were all good, and when questioned in regard to syphilis asserted positively to the end that he had never known a woman.

About the middle of December 1894 while at work in a pig-pen he suddenly slipped and fell violently striking his right infra-mammary region upon the top of a low door, and falling from the door to the floor. He was aware that he bumped his head, but the injury to the side was the only one that he thought of any account.

From the time of the accident he was aware that he was not right, having pain in the right mammary and infra-mammary regions with constant shortness of breath. For this he consulted a physician and took medicine and used local applications for about two months, without decided improvement. About the middle of February 1895 while in the post office in a country store he was suddenly taken with a violent "catch" or "crick" in the back of the neck. He was able to get into a chair and from there on to a couch or settee, from which place he was not able to be moved for some five or six hours. From that time to the time of his death he was not able to turn his head or bend his neck without severe pain, and in fact did not move his head at all without supporting it with both hands. A favorite "hold," when it was necessary to move was with the left hand behind the occiput and the thumb of the right hand under the inner end of the supra-orbital ridge of the right eye. When not moving he often lay for a long time in this posi-

tion. Following the severe attack above mentioned he continued to have pain in the right mammary and infra-mammary regions with soreness on motion, pressure and respiration, and before coming under observation of the writer he had two more similar attacks. The writer subsequently elicited the facts that the attacks occurred suddenly when the patient was somewhat improved and on assuming a vertical position. It was at first asserted that the second attack occurred in the night when the patient was in bed, but close questioning elicited the fact that he had risen to attend to a call of nature. During and between these attacks he had fever and acceleration of pulse but to what degree the writer was not able to learn. Soon after the first attack he began to cough and expectorate freely a muco-purulent material. The attending physician had counsel, but a definite diagnosis was not reached. The case came into the hands of the writer May 5, 1895. The patient was found lying on the right side with the head turned slightly to the right and with the chin near the right clavicle. He continued to occupy this position most of the time for the next six months, turning on the back occasionally but preferring the former position. He was not able to get on, or remain on, the left side at any time. When first seen by the writer the temperature was 101.5 F. and the pulse 120. He was still coughing and expectorating the muco-purulent matter. The writer was told that a sample had been sent to a microscopist of Detroit, who had reported himself unable to find any bacilli of tuberculosis. Another specimen was then sent to Ann Arbor and a similar report received from the microscopist in the University Laboratory. The patient was in fair flesh and though he had been told by his former attendant that his prospect of getting well was small he was in good spirits and very hopeful. He was in full possession of all his faculties and functions except those mentioned above. There was no material difficulty of deglutition, but the mouth could not be widely opened, and the appetite was fair. On account of the extreme sensitiveness of the neck it was impossible to make a satisfactory examination. Distortion of the spines of the cervical vertebrae was suspected, and sought for, but could not be demonstrated with certainty. A moderate blow on the top of the head with the hand caused pain in the vicinity of the cervical vertebrae. Pressure over the spines was not as painful as pressure at the sides of the neck about opposite the bodies of those bones. Percussion over the lower portion of the right mammary region elicited diminished resonance, and auscultation revealed diminished vesicular murmur over the whole mammary region of that side. Within a month the cough and expectoration first diminished and then completely ceased and did not return. The temperature continued uniformly and invariably in the immediate neighborhood of 101 F. for more than six months and the pulse continued for the same length of time between 80 and 120, being generally above 100. The slight fluctuations of temperature that occurred were without assignable cause, so far as could be determined. Within the first fortnight of the writer's attendance he discovered on auscultation a distinct friction or crepitation sound over the whole lower part of the right chest. It continued for about a week and then permanently disappeared, and vesicular murmur increased but never reached the normal. As the percussion note was nearly flat in the infra-mammary and infra-scapular regions effusion was suspected

and the needle of a hypodermic syringe freely used but without discovering any fluid.

At his third visit on May 9, the writer announced the title of this article as his diagnosis. On July 24 it was found absolutely necessary to move the patient to another house some four miles distant. The moving was done with the greatest care on a spring mattress in a spring wagon, on a good country road, and with the patient protected from sun and wind. Notwithstanding these precautions he complained of much pain and nausea and vomited several times during the journey.

At this point in the patient's history he became a township charge and the officer of the township desired to take him to the county poorhouse some ten or twelve miles distant. This desire caused a controversy between the official and the attending physician. The latter affirmed his diagnosis and expressed the opinion that to make the long removal would be dangerous to the patient's life. His opinion finally prevented the removal. In the light of subsequent events the correctness of the position is fully confirmed.

In August a small puffy tumor made its appearance directly under the right nipple and over the sixth and seventh ribs. It was about two inches in diameter and was raised above the surface about five-eighths of an inch. Careful examination now revealed the fact that the continuity of the sixth rib was broken, and on a few occasions crepitus was elicited. The swelling was without discoloration and seemed to fluctuate, but the hypodermic needle repeatedly used failed to find fluid of any kind. The pain in this region still continued but the tumor was not much more sensitive to pressure than the surrounding skin, and the temperature of the part seemed the same as the rest of the body. In October another similar swelling appeared over the upper end of the sternum. It was some larger than the first and was more painful during its growth but was rather less sensitive to pressure than the other. Careful exploration with a hypodermic needle, and also a grooved needle, by the attending and by two other physicians who saw the case, failed to obtain fluid of any kind.

This last tumor for several weeks had a distinct pulsation but there was no bruit. Crepitus was frequently elicited with the fingers of one hand on the right clavicle and the fingers of the other hand over the upper part of the sternum. The nature of these tumors was a matter of much question and their relation to the disease in the back of the neck a difficult problem. Professional friends suggested that they might be malignant. As early as the middle of July it was noticed that while his face was full and of good color his lower limbs and the lower part of his body were emaciating very markedly. At this time there was no motor paralysis or loss of sensation of any part, but it was evident that the nutrition of the parts was suffering. The patellar reflexes were exaggerated. About the first of November the temperature suddenly dropped to the normal for a very few days without assignable cause. Immediately following this the first signs of paralysis appeared and within ten days he entirely lost the use of both limbs. Sensation was not affected more than that the patient said his feet felt sometimes as if they were asleep. The patellar reflexes were still slightly exaggerated, and the reflex action of the spinal cord most marked. When the bed clothes were lifted or when the limbs or feet were stroked or handled they would spasmodically contract with such violence that he would complain of the pain that the

motion of the body caused in the back of the neck. At the first appearance of paralysis he was put upon strychnin sulphate, but on account of the jerking of the paralyzed limbs it had to be discontinued, after which there was improvement in this respect, but the reflex action was very marked till death, in fact, for a few moments after respiration and the heart beat had ceased. Notwithstanding the paralysis of the voluntary muscles of the limbs, the bladder and bowels gave almost no trouble. A catheter was at no time necessary and an injection was sufficient to secure a free movement of the bowels. Soon after the paralysis came on, the exposed points over the trochanter, and crest of the ilium, and sixth and seventh ribs of the right side developed bed sores in spite of our efforts to prevent them. The patient was now almost compelled to lie on his back, and for the last two months of his life he scarcely moved from that position. Between the paralysis and the pain that motion caused in the back of the neck, he had command of only the hands and the lower jaw. During the last three or four days of his life he was so weak in the hands that he could not hold knife nor fork, but it is hard to say whether it was paralysis or muscular weakness. For the last two weeks he had occasional attacks of dyspnea of varying periods of duration. Swallowing and expectoration became difficult and on the afternoon of Jan. 17, 1896 an attack of difficult breathing came on that continued to increase in severity till the time of death at 2:30 A.M., January 19. The mental faculties were retained till within ten minutes of death.

Post-mortem, January 20, thirty-two hours after death, was made in the presence of Dr. Stephenson, of Adrian, Dr. Rice, of Tipton, and Drs. Howell, Jenkins, Woodward, and the writer, of Tecumseh. The body was much emaciated but not to that extreme degree that is often seen in tuberculosis. With the exception of the bed sores mentioned above there was no disorder or discoloration of the skin. Palpation disclosed the fact that the sixth rib of the right side was broken, and that the clavicles were detached from the sternum. The body was turned over on the anterior surface and the spines of the cervical vertebræ examined by palpation and crepitation was plainly felt particularly in the upper ones. On dissection the spines and laminae of the vertebræ were found in apparently healthy condition and when the posterior arachnoid cavity was opened it was free of pus. On carrying the dissection further forward pus poured out at the sides of the bodies of the fourth, fifth and sixth vertebræ. The pus was of thick consistency and creamy in appearance. The bodies of the fifth and sixth vertebræ were entirely consumed and the bodies of those above and below much eroded. According to the books at my command, trouble of this kind is almost always confined to the first three vertebræ, the body and odontoid process of the axis being especially vulnerable, and those below not often affected. In this case the atlas and axis were but slightly diseased, being ulcerated in small extent and the ulceration without discoverable connection with the large field of disease below. It was demonstrated that the abscesses extended downward on both sides of the bodies of the vertebræ into the thoracic cavity. The dissection explained why there was so little deformity in the spines of the cervical vertebræ discoverable before death, there being no perceptible lateral displacement. As the case occurred some eight miles in

the country and as all the physicians present are busy men the dissection was not as thorough as could have been desired, and the question of the "pinching" of the cord was not positively demonstrated, but from the inspection that it was possible to make and from the slight or imperceptible distortion of the vertebrae, it may be set down as almost certain that the cord was not compressed by bone. The body was next turned on the back and the swellings above mentioned investigated. They were found to be abscesses, connected with carious bone, more than half the contents being cheesy. The manubrium was entirely destroyed and the sixth rib was carious. The thorax was opened and its contents examined. With the exception of a few frail pleuritic adhesions the left lung was found normal. The right lung was attached by strong adhesions of the pleura to the entire inside of the right thorax. The lung tissue was healthy as far as could be determined. On each side of the upper dorsal vertebrae the abscesses of the neck bulged into the thorax but nowhere communicated with the pleural cavity. It was positively demonstrated that the abscess at the head of the sternum did not communicate with the abscesses of the cervical vertebrae, as the hand was passed freely up through the thorax between the two without difficulty and without disturbing either of the cavities or finding pus. The abscess of the sixth rib was also isolated.

In this case the use of the hypodermic and grooved needles for the detection of pus was worse than useless for they were misleading. I have no doubt but that at the time they were used the contents of the cavities were mostly cheesy and it was as well or better for the patient for them to remain unopened, but when they were used it was facts that we wished them to reveal, and they deceived us. The trouble unquestionably came from the injury, and it is now apparent that the patient should have been put to bed and kept quiet till the injured bones had time to unite, but it is perfectly certain that no man is sufficiently skillful in diagnosis to detect, or has sufficient authority to adopt, that treatment in such a case. As soon as the writer had made his diagnosis he gave positive orders that the patient should not to be allowed to assume the vertical position under any circumstances, and in consequence he never had another "stitch" in the back of the neck. Further than this all treatment adopted was, at most, of but temporary benefit. The patient did not die of compression of the cord by the bony structures around it, but from the exhausting effect of the long continued pyemia and the pressure of the abscesses upon the cord. That the long continued fever and rapid pulse were due to pyemia can hardly be doubted, for the pressure on the cord was below the heat centers, but it is strange that he never had a chill, and had so little variation in temperature, the latter remaining practically the same to the day of his death. It is probable that the injury to the side was responsible for the pleurisy and that the first abscess to form was in the back of the neck and that the others were metastatic in character. The case is offered for publication that physicians may find in it a possible guide to the diagnosis of a similarly difficult case.

Women in Professional Life. Professor Bergmann says: "I consider women absolutely unadapted to study for or practice the professions to which the universities now offer them access. This incapacity I consider is due to their physical conformation as well as to their moral constitution."

TRANSPORTATION OF INJURED EMPLOYEES.

BY FRANK H. CALDWELL,

CHIEF SURGEON OF THE PLANT SYSTEM.
SANFORD, FLA.

The preliminary treatment given the employe or passenger at the time of accident, resulting in injury, and before the patient is removed to his home or to the hospital, is a service of vital importance; but the scope of this paper will not permit its discussion. The writer intends to confine himself strictly to the subject, as outlined for him by your committee.

Considering the importance of transportation of persons injured it would be natural to suppose that there exists some literature on the subject, but a careful search has failed to reveal any material which could be utilized. The writer is forced, therefore, to give you his experience, trusting that in the discussion of his brief paper, new and valuable ideas will be brought out, which will prove of benefit to those unfortunates, who are often compelled to travel long distances while suffering intense agony from injuries.

It has been conclusively demonstrated that injured persons, except when suffering from severe and extensive injuries to the head, spine, thoracic and abdominal cavities or in a state of profound shock, may, when properly handled, be transported almost an indefinite distance without endangering life or increasing the extent of injury. And it has been further shown by actual experience that a large percentage of the exceptional injuries above mentioned can be safely handled if proper transportation facilities are provided. In cases of lighter forms of injury, as a crushed limb, how should they be transported to the hospital in order that shock may not be induced or increased, or the already mangled parts be further injured?

The nearest surgeon is sent for, and under no circumstances should the patient be carried to him. The messenger informs the surgeon as nearly as possible of the nature and extent of the injury, so that he may come prepared, for not all surgeons have emergency cases, ready for every kind of accident. The surgeon, upon his arrival, controls hemorrhage, anticipates or combats existing shock, and adjusts a temporary dressing. Briefly, he prepares the patient for his journey, whether it be long or short. After due preparation, the patient is lifted gently a few inches from the ground or floor, and a stretcher slipped under him, and he is lowered into it and made comfortable. He is then carried into a coach or baggage car of the first passenger train going in the desired direction. An injured man should never be transported by a freight train. If no passenger train is available in a reasonable time, a "special" should be provided. If the surgeon in attendance fears for the safety of his patient, the chief surgeon should be notified of the fact, and he should instruct the surgeons along the line to visit the patient as the train passes their stations and render any assistance necessary.

As a rule, upon arrival at the hospital, you will find your patient in condition to submit to any operation required for his relief. The plan above outlined in this class of cases, is the one practiced on the system which the writer represents and furnishes the patient almost constant attention from the receipt of injury until he arrives at the hospital; the greatest distance.

between surgeons being forty miles, and usually but twenty.

The comfort and safety of the patient will depend very much upon the stretcher used in transporting him. The writer spent several years experimenting before one was secured which answered the purpose to the satisfaction of himself and patients. Photographs of the ones that have been in use upon our system for the past eight years are submitted for your inspection. It is made of cypress; a light, springy, yet strong, native wood. The stretcher will pass easily through a car door, and two standard car cushions placed end to end, fit it exactly, and can be used as additional protection when required. The bottom of the stretcher is of wire netting, two-inch mesh, and is covered with eight-ounce duck. The netting and duck are fastened to the frame with strips of wood which are screwed on, enabling us to easily clean or repair the wire and duck. The legs fold under, and have heavy, corrugated rubber tips. This stretcher is light, strong, durable, and easily kept clean. It has sufficient elasticity to prevent undue jolting, but not enough to give pain. The

Internal view of Plant System Hospital Car "II."

writer has personally tested it, and can certify to its comfort.

What shall be done with those cases of extensive injury, accompanied by profound shock?

When the surgeon is given sufficient authority, these cases may receive the proper "first aid to the injured" at almost any point on the line of road, for all employes should be instructed that in case of accident, the surgeon's authority is practically unlimited, and that they must obey all orders given by him. By having the coöperation of employes generally, the surgeon is enabled to isolate his patient and give him perfect quiet and rest.

The patient should be allowed to remain at the place where the accident has occurred until the arrival of the ambulance or relief car, in which he is placed and transported to the hospital, either by a "special" or by the first passenger train, as may be considered best.

There have been several plans of ambulance cars proposed from time to time, but they have, in the writer's opinion, been too elaborate, entailing a large

expense upon the company, the officials of which could not see a proportionate benefit; and in my judgment they have taken the correct view of the case. What we need is a strong, stiff car with first-class trucks, furnished in the simplest style, without upholstery of any kind. We need a transportation room, an operating room, and a small consultation room.

A photograph of car "H" of the Plant System is handed you for inspection. This car was a second-hand express, remodeled and refitted according to the writer's suggestions. The total value of the car, as completed, is about three thousand dollars. The doors in each end are hung on the wrong side, so to speak, so that in opening they act as a screen, preventing undue draft upon the occupant of the car; this was done at the suggestion of President Plant.

Now, as to furnishings. The transportation room is furnished with wrought iron beds, with woven wire springs. Heavy, corrugated rubber tips are on the legs, which prevents slipping, and breaks the jar to a great extent. When not in use, these beds are fastened against the walls of the car, and are entirely out of the way. In addition to these, we have an air bed, which when not in use, is folded into a very small compass, and packed into a closet. It takes but a moment to inflate it with air. Lastly, there is a hammock arrangement made to suspend from the roof of the car by strong straps. This hammock has a

External view of Plant System Hospital Car "II."

device of short, strong spiral springs, which absolutely prevents any jolt or jar being communicated to the patient.

The operating room is supplied with an iron, glass-top table, and all necessary appliances for the treatment of shock, and for the performance of perfectly aseptic operations. Sterilizers, etc., are stored beneath the water tank, which is kept filled with sterilized water. All bedding, etc., are packed in the corner cupboard. Bandages, bottles containing chloroform, ether, etc., are in the center cupboard. The rest of the furnishings may be seen in the photographs.

The sitting room is intended only for a place of consultation.

The car is painted with a specially prepared paint, which may be scalded without injury, and will stand disinfection by means of super-heated steam or air.

There should be a relief car of some design for every two hundred miles of road, the car being stationed in the center, having a one-hundred mile run each way.

Gentlemen, it is my opinion that there are few

cases of injury that would not bear transportation if handled as outlined above. If you have cases that you are satisfied will not stand transportation even in the car, you have at your command comfortable quarters for them, and if necessary, you are prepared to perform any operation that may be needed, and remove them to the hospital at a subsequent time.

THE PATHOLOGY, ETIOLOGY AND TREATMENT OF PETIT MAL AND GRAND MAL.

BY FREDERICK HORNER, M.D.

P. A. SURGEON [RETIRED] U. S. NAVY.
MARSHALL, VA.

Both of these forms of epilepsy belong with tetanus and hydrophobia to diseases of the nervous system, petit mal, the congenital or mild form occurring in childhood, grand mal, the inherited and acquired, the result of traumatism and developed during some period of adult life. Both present the characteristic features of the malady, viz., irregular action of muscles usually obedient to volition, curtly defined by Cullen, "*musculorum convulsio cum sopore*." According to the theory of Dr. Carpenter, "Principles of Human Physiology," "the sensory ganglia are the primary seat of that combination of sensibility with spasmodic movements which constitutes epilepsy." The cerebrum also is implicated as occurs by the loss of consciousness preceded by confusion of intellect, impairment of memory and loss of will power over the mental faculties, followed by convulsions and maniacal excitement. There is a marked periodicity, this author adds, in the recurrence of the symptoms. Dr. Todd, "Lumlian lectures," considers there is malnutrition of certain parts of the encephalon which increases the disturbance, and this, when it has attained a certain measure of intensity, manifests itself in the epileptic paroxysms, just as a Leyden jar gets rid of its excess of electricity by a disruptive discharge, presenting like phenomena as when a current of the magneto-electric machine is transmitted through the region of the *corpora quadrigemina*, all the muscles of the limbs, the trunk and eyes will contract and be affected just as in a case of epilepsy. The epileptic by heredity may be considered to be born diseased and even condemned in advance to suffer from the effects. He has an epileptic brain and when the period for development and causes exist epileptic convulsions will inevitably follow. Hence intermarriage with an epileptic should be discouraged, since, as Dr. Brewster, of Baltimore, wisely asserts that "the predisposition in some families is such that any mental or moral strain or any great physical depression is liable to prove the exciting cause of the nervous disorder which is productive of epilepsy." The law of heredity applies to the children of inebriates, adding also to the epileptic list. In the *Quarterly Journal of Inebriety* are noted twelve families of drunkards; during a period of twelve years, there were fifty-seven children born, five of whom became epileptics, two of the epileptics became by inheritance drunkards. Dr. Blackford, Superintendent of the Virginia State Asylum for the Insane, at Staunton, in his late Report for 1894-95, says that in this institution there are 100 epileptics, a class regarded as a *bete noir* on account of homicidal impulses. It is noted as a melancholy fact that this class of unfortunates is increasing in Virginia, and the number in the United States is now 120,000; statistics show an

increase annually along with other forms of mental disease in this and other countries. For example, a writer in the London *Humanitarian*, quoting the report of the registrar general, proves from the statistics, based upon 225,000 cases of certain forms of neuroses, inclusive of epilepsy, that such diseases of the nervous system occupy the fourth rank of maladies most destructive of human life. The report, also, of the commissioners of lunacy, in England, shows that, in 1859, there were of all classes of insane, inclusive of epileptics, 36,762, which number, the London *Lancet* adds, has increased to 74,842, the figures showing, after due allowance for increase of population, 52 per cent. increase above what it was twenty-three years previously. According to the annual report of the Surgeon-General, epilepsy is rare in the navy, in the ratio of 6 per cent., in the class of diseases of the nervous system, a fact readily explained, as seamen are usually rigidly examined before they are admitted to the public service. During a cruise of the U. S. S. *Jamestown*, the writer, as one of the medical officers of the ship can only recall a single case of grand mal occurring in the person of a seaman. As an object lesson and accurate synopsis of this man's symptoms, we quote the details of an identical case as presented in the Bible, for the cure of the Savior, and thus described: "Master, I have brought unto thee my son, which hath a dumb spirit, and wheresoever he taketh him, he teareth him, and he foameth and gnasheth with his teeth and pineth away; and when he saw him straightway the spirit tare him and he fell on the ground and wallowed foaming. When the Great Physician healed the man he lay as one dead." No enlightened physician would hesitate to pronounce such a case to be epilepsy—which the famous Dr. Maudsley of London, has explained to have been aggravated in the case cited by Satanic power, but now is only partially felt by mankind.

Dr. S. E. Smith, Medical Superintendent of the Eastern Hospital for the Insane, Richmond, Ind., says in the *Southern Medical Record*, "Marriages of expediency favor the development of constitutional nervous defects, and if conception has occurred after epileptic convulsions have appeared we may with a reasonable degree of certainty depend upon the reproduction of the disease in the offspring." The habits of modern society also contribute to add to the list of epileptics, too often premature marriages are entered into in the midst of social life, especially in densely crowded cities, where late hours at balls and theaters prevail, and the votary fails to obtain needful rest and sleep and the appetites and passions are under perpetual tension, and when marriage is consummated delicate females, with their husbands, start off on long and exciting journeys, often causing anxiety and nervous disturbance, in the midst of which occurs conception, gestation and, it may be, the birth of offspring inheriting every phase of the neuroses, among which a sudden fright of the mother, renal disease or sexual excess of the marital act, there is developed epilepsy, the latter occurring, as sometimes, after a miscarriage.

The treatment of epilepsy is preventive, medical and surgical. Petit mal, when occurring in early childhood or preceding the period of puberty, if judiciously treated at home by a physician and cared for by intelligent parents, or the trained nurse, may be relieved and even cured. Such examples are referred to by Dr. P. L. Murphy, Superintendent of

the North Carolina Hospital, in the *North Carolina Medical Journal*. They should receive home care, or treatment outside of an institution, thereby escaping the stigma usually attached to a person who has been the inmate of an asylum. Among the first cases presented for treatment the writer recalls, was a robust, country male child; the mother was nervous and hysteric. Between the period of childhood and youth, symptoms of petit mal were developed. Bromids were prescribed; the cold bath; massage and shampooing and the free administration of nourishment, and feeding with milk, especially malted milk prepared by Horlick's Food Co., the more preferable, because to the gluten of wheat and malted barley are added 50 per cent. of pure rich milk, sterilized, all administered with the hope that a more healthy brain might be built up, on the one hand, and a more regular habit induced. This patient was entirely cured of epileptic spasms, though of him might have been answered the Scriptural query already quoted, "How long is it ago since this came unto him?" with the answer, "Of a child."

The treatment of a second case of petit mal may be cited as a warning to physicians and to others who fail to apprehend the importance to protect and guard the epileptic subject during a recurrence of the disease when apparently cured and in the enjoyment of a vigorous and useful manhood. The patient was a young man, aged 28, a farmer. His father was, at an early age, stricken with almost total blindness and loss of hearing, and the mother was of the nervous temperament. While on shore duty, he became my patient, with symptoms of asthma, neurasthenia and dyspnea. He was a man fully developed in height, six feet two inches, weight 140 pounds. The thought was never suggested to question him or his friends concerning his health during the period of youth; far less was there any suspicion that he was an epileptic. When he recovered, unluckily, along with his companions, in the effort to swim and dive in the deep and cold waters of a swiftly flowing river, he was seen to sink suddenly. Though an expert swimmer, he made no effort to rise, and when his body was rescued and carried to land life was extinct. After patient inquiry, I learned from a servant of the family that once while the patient was wood-chopping with him, he suddenly fell upon the ground in an unconscious condition, was speechless for a while, and finally opened his eyes with a dazed look and again began his work. The fatal dive, ten years after the above experience of a paroxysm of petit mal, and which ended his life was inductive of capillary congestion of the cerebral and pulmonary vessels, nervous shock and unconsciousness. Such a case of epilepsy, however mild, ought never to be left beyond the watchful ken of the family physician, since no class of unfortunates are more neglected than epileptics, though a large proportion partially recover and may lead useful lives. Dr. Yarrows, an eminent alienist, has rightly asserted: "Few popular errors prevail and are more prejudicial to the interests of humanity, than that epilepsy and allied disorders are incurable, since a large proportion recover." (London *Lancet*, No. 10, Vol. II.) In a case of traumatic epilepsy, after a fall of twenty feet from the flooring above, the boy landed on the lower deck, suffered no fracture, but was for hours dazed by shock and concussion of the brain and subsequent clonic spasms and epilepsy of hereditary origin. He made a good recovery.

The most successful treatment of the epileptic on a colony farm is likely to prove another grand triumph of medical science, to be consummated fully before the close of the nineteenth century. St. Clement's Hospital for epileptics, in Philadelphia, will shortly establish a colony farm, principally to provide outdoor work for such patients, being the first hospital and colony farm undertaken in America for the sole care of this neglected class. Ohio, New York and Maryland have formed colony farms, and Virginia and other States give evidence that they have a like purpose to make such provision for those afflicted with the "falling sickness," and thereby confer a great boon on the sufferer's family, and often relieving the fears of an entire community. Dr. Drewry, Superintendent of the Central State Hospital, Petersburg, Va., has vigorously prosecuted this enterprise in Virginia. The naval medical authorities fortunately have ample accommodation for the few epileptics of this arm of the public service at the various naval hospitals at home and abroad, though we have known of cases of the kind being sent to the Government Hospital for the Insane for treatment.

SOCIETY PROCEEDINGS.

Chicago Pathological Society.

Regular Meeting, Dec. 9, 1895.

DR. WELLER VAN HOOK, President, in the Chair.

DR. J. B. MURPHY read a paper entitled: "Fibromyoma Complicating Pregnancy; Fibroma of Vaginal Wall." (See page 406.)

PRESENTATION OF SPECIMENS AND DISCUSSIONS.

DR. H. B. STEHMAN presented a *Fibroma*. The patient from whom I removed this fibroma was 35 years of age, married, and

Pregnant uterus with contents, and fibromata.

had never been pregnant before. While she had been aware of the existence of the tumor, previous to within two months she had experienced no discomfort from its presence, and it is doubtful whether she would have sought medical advice except for the fact that her condition was rather to her discredit. Her family physician was somewhat in doubt as to the pregnancy, but the suppression of menstruation, morning sickness, changes in the mammary glands and the appearance of the cervix, added to the rapid growth of the tumor with the attendant pelvic discomfort, left no doubt in the matter. She was told that her choice lay between a miscarriage or hysterectomy, and taking into consideration the size of the tumor, was informed that the risk of the latter was no greater than the former, and probably a little less. At her request the tumor was removed, amputating at the cervix and bringing the stump, previously attached to the peritoneum, into the lower angle of the wound. The operation was done in August, 1893; the convalescence was uneventful, the patient returning home

at the end of five weeks. This growth had developed from the fundus of the uterus in such a manner as to completely hide it from view, but the sketch shows the lobes of tumor separated with the uterus incised antero-posteriorly upon its anterior surface, exhibiting the fetus in utero.

DR. W. T. ECKLEY presented: 1. *Anencephalic monster*, removed post-mortem from an ectopic pregnancy of eight months. The fetus presented the usual appearances of this variety of monster. At the autopsy the inferior mesenteric artery of the mother was of unusual size. 2. *Craniorhachischisis*. The fetus had but six dorsal vertebrae. There were two thumbs on one of the hands.

DR. A. J. OCHSNER presented a *fetus*, showing the effects of an extensive amnionitis. The specimen which I show you is interesting in that it shows in various parts the effects of abnormal pressure upon the fetus. The lower extremities show the effects of this pressure the least. The hand and arm on the left side show the effects of pressure to quite a marked extent. As you see, the hand is clubbed, and there is probably an absence of the lower end of the radius as a result of pres-

Monster, extra-uterine pregnancy. 1, amniotic band; 2, superior maxilla; 3, clubbed hand; 4, liver; 5, colon.

sure. Upon the right side the arm is entirely missing. The colon and the liver project from the unclosed abdominal cavity, from which a portion has been removed also by pressure. There is no arm upon the left side, it having been amputated probably in the same manner. The nose and forehead are deformed. I do not know what to call this deformity; there is a band extending upward from the mouth elevating the upper lip. The left eye is almost entirely closed, and there is a considerable amount of fibrous tissue extending along the cicatricial band. As to the history of this case I will only give it to you briefly. The patient was a laboring woman, 40 years of age, who had formerly borne several children. She came to the hospital in labor, so to speak; that is, she had labor pains. An examination showed that the uterus was probably empty. A diagnosis of extra-uterine pregnancy at term was made and confirmed by various practitioners, among them Dr. John Bartlett. It was decided not to attempt to deliver the child by abdominal section, one reason being this, that notwithstand-

ing we had made a diagnosis, we were not absolutely positive about it. Another reason was that the fetal heart sounds were not sufficiently strong to warrant the necessary danger to the mother. The probabilities of obtaining a living child by an abdominal section were not sufficiently strong to influence us to expose the mother to the danger that would be necessary to deliver the child at term by this method; consequently we waited for six weeks. The child died two days after the labor pains began; at least no further motion was felt, and the fetal heart could not be heard after this time. At the end of six weeks we removed the child by abdominal section. The placenta was left in place, the sac attached to the abdominal wall, and the cavity from which the child was removed was packed with gauze in the form of a Mikulicz drain. In the meantime the amniotic fluid had decreased to a very marked extent. At the end of three weeks the placenta was removed, after which the wound healed by granulation, having remained aseptic throughout. The patient returned to her home two months after the operation and carried about some sick children for two or three weeks, and as a consequence developed a ventral

Monster, extra-uterine pregnancy. 1, amputation at shoulder; 2, liver; 3, colon.

hernia, which gave us an opportunity to make an accurate diagnosis concerning the location of the fetus. During the first operation we supposed the fetus was in the broad ligament, and that the placenta was attached in the direction of the uterus. However, in the secondary operation it was an easy matter to determine the location of the extra-uterine pregnancy, because the ventral hernia had attached to it what was left of the sac which had contained the fetus. It consisted of the broad ligament which was spread out at one end. At the upper end to the right the ovary was located; consequently we then made a positive diagnosis that the fetus had lain in the broad ligament. I will say regarding the history of the mother that at about the third month she began to have repeated hemorrhages which continued for some eight weeks, confirming our diagnosis of extra-uterine pregnancy. Six weeks after the second operation the mother again became normally pregnant.

DR. JOSEPH HAVEN presented a *kyphocephalous monster*. I

do not present this little monster for the purpose of opening the old controversy as to the possibility of maternal impressions being imparted to the fetus in utero, as it would lead to a great deal of discussion, but because this little freak of nature is interesting. I will briefly give the history of the case, and ask you to compare the two specimens before you. Some twelve or fourteen years ago I was in attendance upon a family in this city, one of whose members was a little girl 8 or 10 years old, extremely nervous and high strung, who possessed an uncontrollable fear of dogs. Anything in the canine race, even the picture of a dog, would distress her. Her mother explaining the matter to me said that while carrying the child in utero she had been frightened by a dog, and that the girl had inherited that fear. As the child grew older she did not outgrow that tendency. During an attack of typhoid fever, in her delirium she had frequent visions of dogs, so that it was often necessary to employ narcotics to quiet her. The child grew up and was married, shortly after which she became pregnant. About the sixth week of pregnancy I was sent for one afternoon in a hurry. I found Mrs. D. hysterically excited. I was told that in going out of the yard a neighbor's dog jumped upon her and terribly frightened her. She was put to bed, began to flow, and a miscarriage seemed imminent. But she was tided over. I saw her daily after that for some time. She assured me that her child would be marked like a dog. I tried to disabuse her mind of this idea. Time went on and about the third month the same dog jumped on her again and bit her in the foot, inflicting a slight lacerated wound. It was some time before I could go to the case and when I reached the house a miscarriage had just taken place. I took possession of the fetus, being careful that the mother should not see it. On

Kynocephalous monster with skull of dog.

account of the peculiarity of the specimen removed I secured the dog that had been the occasion of so much trouble, and to-night I show you the skull of the dog which I would like to have you compare with the little monster.¹ Those who believe in the transmission of maternal impressions will get some consolation from examining these specimens, and those who believe such results happen as mere coincidences will have to account for this freak as best they can.

DR. JOS. B. DE LEE (by invitation) presented a *hypoplastic monster*. The specimen which I shall present to-night is a rather rare one. It belongs to that class of monsters that are described as hypoplasias, and the hypoplasia in this case occurred at an early stage of development. The fetus is well developed. You see only the upper half, but the lower half was perfectly normal. The technical name for the deformity which you see is cyclops, or synophthalmus, or another name for it is arrhinencephalus. The deformity is produced by an arrest in growth of the three anterior cerebral vesicles of the brain. The interior of this skull, if I had permission to dissect it, would show a large cyst which would represent the cerebellum, and at the base would be the cerebellum normally developed. Anteriorly there has been no distinction between the eye vesicles. They did not separate, and therefore form the eye in the median line. This monster shows a well developed single eye. Owing to non-development of the cerebral vesicles

flexion was not complete, so the nose, or the representative of it, is this process which you see above the eye. It is a beautiful specimen in that it shows one single eye which is complete.

The other specimens which have been presented by the members were interesting in several respects, and they belong also to the class called hypoplasia. One of them was a hypoplasia, the result of pressure from amniotic bands. The extra-uterine pregnancy cases are particularly liable to present amnionitis. This amnionitis has been disputed by several authorities who claim that a normal amnion can, in the absence of the liquor amnii, at an early period become attached to part of the young fetus and thus interfere with its development. Abdominal hernia is sometimes ascribable to the same cause. The non-development of the forearm in this fetus presented by Dr. Ochsner is an interesting feature ascribable also to amniotic bands. It is an anencephalus, and the specimen by Dr. Eckley was a similar one. The other was a specimen of craniorachischisis, a common deformity. None of the gentlemen have given us any points about the clinical history or course of monsters. Possibly that was because we have here no monsters that would cause obstruction in labor. A diagnosis of double monster before labor is impossible. No one has yet diagnosed a double monster before labor, and the nearest any one has come to it was to diagnose twins. A diagnosis of single monster has been made several times. In a case like the one reported by Dr. Eckley, the absence of the brain could have been diagnosed from the abdominal findings. Another anomaly that occurs in single monsters that is probably more common is hydrocephalus. That could be diagnosed. The double monsters that cause trouble do so in three ways. First, those monsters that have a reduplication of the upper half of the body, with two faces attached to one body. These are called diprosopus, or double-faced monster. These monsters cause a disturbance in labor by the marked increase in the circumference of the part. The other form of monster of this class which will cause trouble in labor is the one in which there is an increase in the lower half of the body, where there will be two individuals joined together below. This is called dipygus, and there may be three or four legs. Another form of monster for our study clinically is that in which there are two individuals adherent at the head or breech. One is called craniopagus and the other ischiopagus, or the pygopagus. Some three years ago there was an ischiopagus monster shown in the museum here in which two children, then 16 months old, were attached to each other by the buttocks. Such a case would cause little difficulty in labor, needing possibly a little traction. Thirdly, a most interesting monster is that like the Siamese twins, with two children joined together at the breast, or thoracopagus. Since this junction is very movable, anomalies can occur in which one fetus will be half delivered, and the other will apply itself transversely across the inlet. The case resembles one of interlocked twins and may cause the severest kinds of dystocia.

In the treatment of these three kinds of monsters the method to be pursued will be plain. In the first group, forceps or version and extraction, or if a dipygus extraction by all the feet that present. In the second group, traction on the body of the fetus delivered. In the third group, version of the second twin, then bring the first out, finally deliver the second by the breech. As a general rule breech presentations are more favorable in labor in monsters, and one should seek to turn, if the opportunity presents.

DR. GUSTAV FÜTTERER discussed: 1. *Metastasis of carcinoma from the labia majora*. "You know that generally carcinoma of the labia majora by metastasis make their appearance in the inguinal glands. In this case the carcinoma of the right labia was removed very early, and some time after that the patient died. I made a post-mortem examination and found a nodule in the myocardium. I examined the cells and found that they were like the cells of the upper layers of the skin containing eleidin. Perforation into the pericardial sac had taken place and from here an absorption of the cells by the stigmata of the pericardium was effected. You see the epithelial cells mostly in columns. Most of them at right angles to the surface of the pericardium, some parallel to it, all filling out the lymphatic spaces. Fresh specimens of these parts show that the cells had retained their original character entirely. As far as I know, this is the only case of its kind that has been observed or reported. It may be there are more, but I do not know of any where such a metastasis has occurred from such a superficial carcinoma of the labia majora."

2. *Histogenesis of giant cells, illustrated in a carcinoma of the cervix uteri*. "You wonder, doubtless, why I show you this because you see such cases so frequently. The reason why I do so is this, that there are large cells which contain comparatively large nuclei and I consider this important as an his-

¹ The general appearances are well shown in the photograph which is reproduced here. The peculiarities not brought out by the photograph are, the extreme breadth of the shoulders, the great chest development and the caudal appendage. The tail was originally three quarters of an inch in length, but has suffered from much handling. The sulcus around the neck was occasioned by the cord originally used to suspend the specimen in the jar.

tologic fact. If you will look at the first specimen you will notice that there is extensive necrobiosis in most of the alveoli of the carcinoma. You will also notice (with low power) that in the necrobiotic parts there are large red spots, and as there has been employed an elective staining for nuclei, you must recognize that these spots are large nuclei. The second specimen, with the high power, shows that these red bodies are nuclei. What does that mean? The necrobiosis shows that there is a lack of nutrition. With lack of nutrition we have lack of water, and according to the experiments made and published by Prof. Jacques Loeb, of the Chicago University, in 1892, such a deficiency of water brings about, first a rigidity of the protoplasm, while the nuclei may multiply, and then, when increased, a rigidity of the nucleolar substances, which will prevent their division. In this case, I would say, there was a local drought, as it were, sufficient to cause a rigidity of the protoplasm, preventing its division, sufficient also, to prevent the division of the nucleoli, but not sufficient to prevent the increase in the bulk of the latter's substance. However that may be, our findings in the specimens which I show to you, and our observations on giant cells in tuberculosis confirm the results of Loeb's investigations and I believe that the latter will bring to us the long-sought-for clue as to the histogenesis of the giant cells. An excessive high or low temperature, or a lack of oxygen (vacuum), will cause the same rigidity of the protoplasm and nuclei successively and, in dealing with those matters, we must always remember, that protoplasm is also present in the nucleus. The latter fact explains the similarity of reaction of the nucleus, and the protoplasm, which only shows a qualitative difference between either."

DR. J. B. MURPHY read a paper on

INTESTINAL OBSTRUCTION FROM ENTEROLITH.

J. McC., aged 47; male; admitted to Cook County Hospital Dec. 1, 1895. Family history negative; used intoxicants and

Enterolith.

tobacco to excess. Had had gonorrhea three times. Denied syphilis. Suffered from typhoid fever when a boy. About twenty years ago was seized with sudden pain in the epigastrium. He described the pain as a cramp; says it lasted but a few hours; since that time has had many similar attacks, each resembling the present one. Present illness began five days ago. After a large bowel movement, was attacked with severe, steady, aching pain in the epigastrium. This compelled him to go to bed. The following evening he began to vomit a dark-colored material. After a few hours, the odor of the material ejected became offensive. It was impossible to produce a bowel movement. The severe pain, vomiting and inability to produce a bowel movement has continued up to the present time.

Physical examination: Patient well nourished; conjunctiva slightly jaundiced; tongue dry and heavily coated; breath very offensive; face has a pinched expression; knees drawn up. Abdomen distended; irregular elevations can be noticed in its surface; liver dullness normal. Peristalsis movement could be recognized through the abdominal wall. Auscultations revealed strong peristaltic action, most marked in the right epigastrium. No tenderness except to the left and a little above the umbilicus, where deep pressure produced pain. Pulse 90; temperature normal.

Diagnosis: Mechanic ileus without intestinal strangulation.

Celiotomy was performed Dec. 6, 1895, assisted by Drs. Beasley and Wood. Median incision. Small intestine very much distended, a coil secured and held by an assistant. Splenic flexure of colon located; found contracted and empty; advanced along the transverse colon until near the median line, where a nodule was felt in the small intestine. This nodule was drawn

into the wound. The intestine about the nodule was about two inches in diameter, and below, five-eighths of an inch. It could readily be seen that the obstruction was produced by a large foreign body in the bowel. Parallel incision was made in the bowel, and the enterolith extracted. Opening closed with Czerny-Lembert suture. Abdominal wound closed with silk wormgut suture. No drain. The enterolith weighed twenty-five grams. It measured 4.5 c. longest diameter, and 2.75 c. shortest diameter. Its circumference was 12 c. The center appeared to be composed of an old dry mass of plum-pudding, to which other material had become adherent. It would be interesting to know whether this had been the cause of pain for twenty years preceding the operation, and if it had been in the canal that length of time where it was lodged. We do know that large foreign bodies may remain in the bowel for months without producing manifestations of their presence. The differential diagnosis between strangulated ileus and obturation ileus in this case, was based on the fact that the man had suffered for five days from obstruction and still was not collapsed nor depressed, which he would have been, had the intestine been strangulated. The patient made an uninterrupted recovery.

Chicago Ophthalmological and Otological Society.

Regular Meeting, Dec. 10, 1895.

DR. F. C. HOTZ in the chair.

There were twenty-three members and visitors in attendance. The minutes of the last meeting were read and approved. The Secretary read the applications of Drs. S. L. McCreight and T. A. Woodruff, Chicago, and Dr. H. V. Würdemann, of Milwaukee.

DR. WÜRDEMANN showed the society some asbestos floss which he had been using instead of absorbent cotton, the advantage being that it can be held directly in a flame and sterilized in that way. It is very soft and more absorbent than absorbent cotton. He also showed asbestos cord which can be used for drainage, cloth of different thicknesses, and asbestos paper. It absorbs thick pus better than absorbent cotton, and is quite light even when wet.

DR. N. H. PIERCE then read a report of "Six Cases of Removal of the Ossicles for Different Causes." The report will be published.

DR. C. W. HAWLEY, some years ago, had seen several operations for sclerosing catarrh in which there was much tinnitus. The first case that he had seen was so very much improved by the operation, that he had very strongly recommended it to several patients subsequently. But in the next five cases that he saw the results were so disastrous that he had not recommended the operation for some time. In one case there was complete paralysis of the facial nerve lasting some time, and all of the five cases were not only not improved, but as a rule made worse.

DR. WÜRDEMANN had had considerable experience in doing this operation. He had had six cases of sclerosis and about thirty cases of chronic suppuration within seven years on which he had operated. The first six chronic purulent cases had a successful result. The next two cases were of the dry form. The first, a young girl, both ears were operated upon with a good result in both. At first, he had great difficulty in, and operated a number of times for, preventing the renewal of the drumhead. It grew very rapidly. At the end of a year the girl's hearing was worse than before the operation, but the tinnitus was better. In the second case, a woman of 36, the tinnitus was lessened, but the hearing grew worse. In another case, a man of 60, an Australian, all methods of treatment were tried without any result—in fact, he got worse under treatment. He was operated upon and made absolutely deaf. In three other cases the tinnitus was diminished, but the hearing not improved. In the suppurative cases about 60 per cent. were cured as far as suppuration was concerned; in 20 per cent the suppuration was not lessened, and in 20 per cent, it was somewhat lessened. Of all the suppurative cases, about one-third had the hearing improved by the operation. Dr. Würdemann has reached the point where he believes that he will not operate on any sclerosis case where the stapes is fixed; and as far as suppurative cases are concerned, the operation is justifiable only in those cases in which the suppuration comes from the attic as well as from the other parts of the middle ear. These cases usually have a necrosis of the incus or malleus; we most often find the incus diseased, when we find it at all, which is not very often, as it usually has escaped from the ear. We sometimes find the osseous canal very much roughened, and it is necessary to scrape this in order to effect

a cure of the suppuration. The point of the operation in attic suppuration is that by means of it free drainage is obtained, and the whole benefit to the case arises from this. He had done the Stäcke operation three times with immediately successful results. This operation may be considered the ideal one. A preliminary opening of the drumhead in the sclerosing form of inflammation is not apt to give any result, because these cases usually have free communication with the outer ear through the Eustachian tube, and nothing is gained by making an opening in the drumhead. This is especially the case where the drumhead is atrophic.

DR. DODD had recently operated upon two cases. One which he had followed for six weeks was a woman with exceedingly annoying and severe tinnitus. She could not sleep: she could not control herself because of the incessant and loud noise, and came to Dr. Dodd for that only. She had been treated for more than a year by different methods with no benefit: in fact, getting worse, and at the time he saw her the ear was perfectly deaf for conversation. He removed in this ear the drumhead and the malleus, the tinnitus was very much improved, and, strange to say, the hearing also. About two weeks after the operation suppuration started in the middle ear, due to some carelessness, but was easily controlled in three weeks. The amount of improvement both in the hearing and in the tinnitus in this case was very marked. Whether this continued or not, the doctor does not know. The other case was not nearly so severe a one, and the operation improved the hearing somewhat. The tinnitus had not been very severe and the patient paid but little attention to that part. It apparently was about the same.

DR. HOLINGER had had fair results from the operation where the ossicles were necrosed. In the dry catarrh, where inflation improves the hearing, he considers the operation contra-indicated. In true sclerosis improvement can hardly be expected. Where the Rinne test is negative, no results can be expected from operation.

DR. PIERCE, in closing, said that he wished it understood that in all of his cases, except one, all other methods of treating the ears were tried before operation was resorted to. Although he knew that Dr. Sexton recommended the operation indiscriminately, he had seen several cases from Sexton's hands where certainly marked improvement had resulted. One case he remembered particularly, where a lady was operated on in her worst ear some five years ago, and now the worst ear is the better one, the ear unoperated upon being the worst at present, thus establishing the claim that Sexton makes, that the operation tends to check the process. The Stäcke operation is an ideal one, but many patients will not submit to it. He asked if any of the members had had any experience with Lucae's probe?

DR. GRADLE said that he had used the probe a little, not methodically as Lucae recommended, and had no results from it.

DR. WÜRDEMANN had tried it in several cases, but without results in most of them. He did not consider, however, that he had given it a fair trial except in one case, the case of the man of 60 whom he had made stone deaf in one ear. He used Lucae's probe methodically, as recommended by Lucae, in the other ear, and had surprisingly good results.

DR. MANN showed a modified stomach tube which he had used for carrying off the water in syringing the ear. The side of the funnel-shaped end had been cut away and this was attached under the patient's ear by means of cords passing around the head.

SELECTIONS.

The Fate of Micro-organisms in Inspired Air.¹—In a communication we recently had the honor of reading before the Royal Medical and Chirurgical Society² on "Microorganisms in the Healthy Nose," we calculated that 1,500 organisms are inhaled into the nose every hour. This was the lowest estimate, and we quoted experiments to show that it must be a common event—at least, in our average London atmosphere—for 14,000 organisms to pass into the nasal cavities during one hour's tranquil respiration. The fate of the thousands of microbes which thus enter the human body is a question of great pathologic interest, and this increases when it is remembered that the expired air is practically free from germs. A study of the subject should

therefore be instructive in showing how the human economy deals with the hosts of organisms which are continually invading it through the air we are always breathing. The fact that inspired organisms do not, as a rule, reach the air cells was first pointed out by Lister. He observed that "in simple fracture of the ribs, if the lung be punctured by a fragment driven inward upon it, the blood effused into the pleural cavity from the wound in the highly vascular organ, though freely mixed with air which enters the pleura through the same orifice, undergoes no decomposition, as is clearly implied by the absence of any symptoms of pleurisy in such cases. The air is sometimes pumped into the pleural cavity in such abundance that, making its way through the wound in the pleura costalis, it inflates the cellular tissue of the whole body; yet this occasions no alarm to the surgeon, unless the openings in the parietal pleura become insufficient to permit free egress for the air, which then becomes pent up in the serous cavity and, distending it far beyond its natural dimensions, encroaches so seriously on the other lung as to embarrass or even abolish its functions."

In a postmortem examination on such a case ten days after the receipt of the injury Lister found the enormously distended pleura free from effusion and perfectly smooth and healthy. This observation was explained by the atmosphere being filtered of germs by the air passages, "one of whose functions it is to arrest inhaled particles of dust and prevent them from entering the air cells.³ Later Tyndall showed by his experiments with a ray of light in a dark chamber that expired air—or, more exactly, the last portion of an expiration—is optically pure, *i. e.*, that respiration has freed it from the particles of suspended matter with which it is laden.⁴ In 1882 Gunning of Amsterdam showed that expired air contains no microbes capable of provoking putrefaction in sterile liquids through which it has been passed,⁵ and in 1887 Strauss and Dubreuil independently arrived at a similar conclusion.⁶ They spent thirty minutes in expiring from 200 to 300 liters of air into tubes, in the bottom of which was a layer of sterilized alkaline bouillon. The greater number of these tubes remained sterile; a few showed growths of microbes and molds, doubtless due to accidents of manipulation. Grancher has made many experiments with the expired air of phthisical patients and has never found in it the tubercle bacillus or its spores. Charrin, Karth, Cadéac and Mallet have made analogous experiments with negative results. In a further series of confirmatory experiments on this subject Strauss⁷ showed that on an average of 809 bacteria and spores inhaled only one single germ is expired. Now, as the air is practically freed from all germs by the respiratory act, we have to consider where and how the thousands of organisms are arrested in the air passages. The experiments of Hildebrandt⁸ would tend to prove that the air is entirely freed from all germs before reaching the trachea. In controlling this we have examined the mucus from the trachea of all animals recently killed in the laboratory, neglecting, of course, any that had suffered from affections of the respiratory tract. The opportunities are too few to be recorded numerically, but up to the present we have always found this mucus to be quite sterile. The above shows that the fate of microorganisms must be sought for principally in the upper air passages. We therefore commenced with the nasal fossae, and our experiments are published in the paper already referred to.⁹ The result we arrived at was that "the mucous membrane of the healthy nose only exceptionally shows any microorganisms whatsoever. The interior of the great majority of normal nasal cavities is perfectly aseptic. On the other hand, the vestibules of the nares, the vibrissae lining them, and all crusts formed there are generally swarming with bacteria." These two facts seem to demonstrate that the vibrissae act as a filter and that a large number of microbes meet their fate in the moist meshes of the hair

which fringes the vestibule. Not only does this arrangement arrest the ingress of germs, but others which have penetrated into the nose are rapidly ejected by the action of the ciliated epithelium.

To obtain an idea of how rapid a movement might be imparted by ciliary action we performed the following experiment. A frog was pithed and the lower jaw cut away, exposing the dorsal wall of the pharynx, which in this animal is covered with ciliated epithelium. On this a particle of wet cork was placed, and it was most striking to observe the rapidity with which it was conveyed along to the esophagus. We found that it traveled at the rate of 25 mm. (one inch) per minute. In the normal frog the rate is probably more rapid, as ciliated epithelium thus exposed is soon damaged. It is difficult to give an analogous demonstration, in the human subject, as a foreign body of any tangible size, even powdered magnesia, is apt to act as an irritant and produce a free secretion of watery mucus, which rapidly washes it down into the vibrissæ.

With regard to the microorganisms which may be deposited in the Schneiderian membrane, we carried out the following series of experiments on four different occasions. Cultivations were made from the vibrissæ and from the mucous lining of the nose of one of us who acted as the subject. The cultures from the vibrissæ invariably showed yellow and white colonies in abundance, while those from the mucous membrane were almost invariably quite sterile. This served to show that there was no red growth of the bacillus prodigiosus, the organism had been prepared, and a sterilized loopful was deposited on a distinct point on the septum, well within the vestibule. Cultivations made from the spot immediately, or within five minutes, showed an abundant confluent growth. When taken after fifteen minutes' interval the cultures on agar showed already a diminished growth. After thirty minutes the growth had markedly decreased; at the end of one hour it had diminished by 75 per cent. and consisted of a considerable number of discrete colonies: frequently no trace of the loopful of the bacillus prodigiosus could be detected after eighty minutes from the time it had been deposited, and after two hours had elapsed in no case did we get any growth whatever when cultivations were made from the spot inoculated. We would note that this observation had reference to a loopful of pure culture, large enough to be detected as a distinct red spot on the mucous membrane, and therefore containing myriads of organisms. What became of them all we are at present not prepared to say. During the two to three hours that the nose was kept under observation cultivations were continually being made from around the spot, but never once did they show any bacillus prodigiosus. We carefully examined the opposite wall of the nasal cavity and only once found a red growth among the vibrissæ. Wurtz and Lermoyez¹⁰ hold that the nasal mucus itself exerts a bactericidal influence on all, or nearly all, the pathogenic agents. So far we have been unable to corroborate their researches; but this may be due to our want of success in obtaining an appreciable quantity of sterile mucus. To collect this secretion it is necessary to introduce a sterilized cotton-wool plug into the nasal cavity and leave it there for some time. We have found it practically impossible to do this without contaminating the tampon with the vibrissæ at the orifice. Now, as we have shown, these are never free from germs, and the nasal mucus with which they come in contact was in no case sufficiently germicidal to prevent their free growth when sown on gelatin plates. In some cases we left the nasal mucus in a sterilized glass for from one to sixteen hours at room temperature, during which period it had abundant time to exert its destructive action on the germs which had adhered to it when passing out along the vibrissæ. Nevertheless, there was always a free growth of yellow and white colonies when gelatin plate cultivations were made from it. Wurtz and Lermoyez have only published their researches on the action of nasal mucus upon the anthrax bacillus; but still they hold that the same germicidal effect is exerted in different degrees of intensity on other microbes.

Although we have been unable to obtain any proof of bactericidal qualities in nasal mucus, we have satisfied ourselves that it is possessed of the important property of exerting an inhibitory action on the growth of microorganisms. This is shown by what we have said above and by the following experiment. A loopful of a fluid culture of the bacillus prodigiosus was mixed with a small quantity of nasal mucus. From this gelatin plate cultivations were prepared, some immediately and others at various intervals up to thirty-six hours; on each occasion the same quantity of the mixture was used for inoculating the plates. The number of colonies of the bacillus prod-

igiosus which developed in various plates was practically identical, showing that no increase in the number of organisms had taken place, and also that no germicidal action had been exerted during even many hours' exposure to the mucus.

We have made a great number and variety of experiments in order to test the bacterial condition of the air before and after passing through the nose. For a long time the conflicting and contradictory results showed us that there was some error in our methods. These were based on the plan adopted by Bloch for testing the warming and moistening influence of the nose. Finally, and only lately, we succeeded in approximating closely to the normal condition of affairs by designing the following method. A sterilized glass cannula, shaped like the tube of a post-nasal syringe, was introduced into the post-nasal space of one of us. The end of this glass tubing, projecting through the mouth, was directly connected with a glass tube passing down through a rubber cork to the bottom of a large-sized test tube. Fifteen c.c. of liquified sterile nutrient gelatin had been poured into this tube, the bottom of which was narrowed so that quite an inch of the glass tubing passed below the surface of the liquid. Another piece of glass tubing passed up through the rubber cork and was connected with a mouth-piece, through which inspirations were made regularly by the other observer so as to imitate normal breathing. In this way the air passed freely along both nasal cavities of one observer, entered the glass tubing, and bubbled through the layer of gelatin. Ten respirations were thus taken and an Esmarch roll cultivation was made. In an analogous amount of laboratory air we found twenty-nine molds and nine bacterial colonies; whereas after passing through the nose the air contained only two molds and no bacteria. On another occasion we found in nine liters of laboratory air six molds and four bacterial colonies, while the same quantity of air after passing through the nose exhibited one mold and no bacteria. We see, therefore, that practically all, or nearly all, the microorganisms of the air are arrested before reaching the naso-pharynx; probably a majority are stopped by the vibrissæ at the very entrance of the nose and those which do penetrate as far as the mucous membrane are rapidly eliminated. The nasal mucus is an unsuitable soil for the growth of organisms, and hence is an important factor in that it does not further their multiplication. The removal of the intruding organisms from the Schneiderian membrane is probably in the main due to the action of the ciliated epithelium, assisted by the trickling of mucus and the lachrymal secretion. Phagocytosis may share in the work of removal, though to a small extent, for we have only once found phagocytic cells containing bacteria.—ST. CLAIR THOMSON, M.D. and R. T. HEWLETT, M.D., in *The Lancet* (London), January 11, 1896.

Syphilis in Infants.—Boulengier denies the possibility of transmitting syphilis to the offspring by means of the spermatozoid. He thinks that syphilis in conception is an embryologic impossibility, and that where children are born with it, the disease was acquired *in utero*. Syphilis may be latent in the mother, but it finds the placenta such a fine culture medium that it develops there and infects the offspring while sparing her. Although the actual syphilis is not transmitted by the father in conception, yet all the symptoms of degeneracy that it entails are liable to appear in the child, inherited directly from him. He cites many cases to support his theory, among others a couple with no venereal antecedents of any sort. The husband contracts the disease when his wife is in the fourth month of pregnancy. The child is born with pronounced syphilis. A month later, the mother who had until then shown no signs of infection, was attacked with roseolar and papular eruptions.—*Presse Médicale Belge*, November, 1895.

Statistics of Anesthetics and Ruptures in Scandinavian Countries.—By concerted actions of the surgeons of Sweden, Finland and Denmark, determined upon at the Surgical Congress of 1893, at Gothenburg, statistics have been collected on these two subjects and published in the *Nordiskt Med. Arkiv*, xxvii, Nos. 4 and 5. Full details are given from which we cull the following: The mortality in 15,052 cases of anesthetics employed is 0.10 per cent. with chloroform; 0.15 per cent. with ether, and 0.18 per cent. where both were used. Five cases of death in the course of the narcosis from chloroform make a ratio of one in 2,257 cases. Gurlt, of Berlin, reported one death in 1,924 cases with chloroform, and one in 26,000 cases with ether, from a total of 151,000 cases of anesthesia (*Sem. Méd.*, 1894, p. 202). In statistics of surgical treatment of hernia, there were 68 deaths in 1,733 cases treated, a percentage of 3.9. This is higher than it should be, as many deaths were due to pre-existing complications. The methods of Bassini, Czerny, Macewen and Kocher were followed, with a preference for Bassini's.

DR. THOMAS DOVER, THERAPEUTIST AND
BUCCANEER.

In the *London Lancet* for January 4, Dr. WILLIAM OSLER, of the Johns Hopkins University, gives an interesting historical contribution concerning the Seventeenth Century physician who gave to the world the immortal Dover's powder. According to Dr. MUNK, librarian of the Royal College of Physicians of England, quoted by Dr. OSLER, Dr. DOVER was a Bachelor of Medicine of the University of Cambridge, but the name does not appear on the list of graduates. THOMAS DOVER was born in Warwickshire about 1660, and after studying at Cambridge and with the famous Dr. SYDENHAM, settled down at Bristol, for centuries the home port for adventurers, privateers, and slave traders. He was nearly fifty when he joined in a commercial and piratical venture with a number of Bristol merchants. Two ships, the *Duke* and the *Duchess* were fitted out for a voyage to the South Seas, from which WILLIAM DAMPIER, the circumnavigator of the world, had brought wonderful tales of Spanish riches. DAMPIER, who had come to grief in his last expedition to those regions, was taken along as pilot, while DOVER went as third in command to CAPT. ROGERS, and appears in his narrative as CAPT. DOVER. The expedition was memorable for two events. On Feb. 1, 1709, the ships arrived off the island of Juan Fernandez, and CAPT. DOVER was sent ashore in the pinnace, brought back with him to the ship a couple of days later a man clad in goat skins, who had been left on the island four years and a half before. This was ALEXANDER SELKIRK, the original Robinson Crusoe. Later the expedition sailed up the South American Coast, and found what

it was seeking in the two cities of Guayaquil, which it attacked and sacked. DOVER led the van, and cured the sailors of the plague which broke out after the capture of the cities. After cruising in the Pacific for another two years for the Spanish treasure ships they returned to England in 1711, having collected plunder to the value of \$850,000. DOVER's share made him a wealthy man, and left him free to wander about the world for some years.

He settled down in London as a physician in 1731, carrying into his practice the pugnacious habits of his buccaneer's life. To attract public attention, he published his book, "The Ancient Physician's Legacy to his Country; being what he has collected himself in forty-nine years of Practice; designed for the use of all Private Families." The book ran through eight editions, the last apparently being published in 1771. On page 18, on the section of gout, is given the formula for his famous powder:

"Take opium one ounce, saltpetre and tartar vitriolated each four ounces, ipecacuanha one ounce. Put the saltpetre and tartar in a red hot mortar, stirring with a spoon until they have done flaming. Then powder them very fine; after that slice in your opium, grind them to a powder, and then mix the other powder with these. Dose from forty to sixty or seventy grains in a glass of white wine posset going to bed, covering up warm, and drinking a quart or three pints of the posset; drink while sweating."

The publication of the book made a great noise, and brought DOVER into many quarrels with his fellow practitioners, who treated him as a quack, as they did SYDENHAM, for that matter. He carried on a bitter war against apothecaries, too, and died in 1742. His powder is still in the British pharmacopeia.

THE BRITISH ARMY MEDICAL OFFICER.

At the closing exercises of the seventy-first session of the Army Medical School, Netley, England, the prizes were distributed to the student officers by the Adjutant General to the Forces, GENERAL SIR REDVERS H. BULLER. The officers constituting the staff of the school and of the Royal Victoria Hospital were present, the principal medical officer, SURGEON MAJOR GENERAL GIRAUD acting as Chairman. The Director General of the Army Medical Department, SIR W. McKINNON was prevented by sickness from attending. Nine candidates on probation for the British Medical Service and eighteen for the Indian Medical Service passed the examinations which determined their final positions in order of rank. According to the report of the proceedings in the *Lancet* of February 8, the address of the Adjutant General did not create a favorable impression on the medical men present. He eulogized the profession of medicine and urged the young officers to be proficient in this their special work; and on the whole he gave the impression that

the professional qualification was the only one which would be regarded at headquarters in the consideration of promotions and rewards. An address of this character would have been all very well forty years ago, prior to the organization of the Army Medical School; but when it is organized, as it is now in all armies, that the ever present duty of the Medical Staff is to prevent sickness and preserve the efficiency of the fighting force the address of SIR REDVERS BULLER must be regarded as that of one who has not progressed with the age in sanitary matters but has retained the view which prevailed up to the time of the Crimean War that a doctor was of use only to cure the sick. Every military medical officer should be a good doctor, but he must be something more than this to enable him to perform the various official duties required of him; and as it was to fit him for the performance of these very duties that the Army Medical School was organized the address of the Adjutant General was particularly unsympathetic and in fact inappropriate to the occasion. Fortunately, in the United States the status of the medical officer is defined by the intelligence of the country as expressed by Congressional legislation. Fortunately also, our military officers are progressive, so that such an address by the Adjutant General or any other military officer of our Army would be an impossibility. We remember the kindly welcome which LIEUTENANT GENERAL SCHOFIELD gave to the student officers of our Army Medical School at the close of its last session and how he took occasion to impress upon them the importance and responsibilities of their position as sanitary officers, showing at the same time that by reason of their professional standing no officer of the army came into more intimate and friendly relations with others than the officers of the Medical Department.

THE ALLEGED FREQUENCY OF INSANITY AMONG FARMERS.

A homeopathic alienist down east has the credit of making the suggestion that early rising is a potent cause of insanity and is accountable for the undue prevalence of that disorder among the farming community, who are notoriously given to the practice that the old nursery rhyme so mistakenly says makes one "healthy, wealthy and wise." The suggestion contains two propositions, apart from that that early rising is bad for the mental health, viz., that agriculturalists are specially liable to insanity, and that this liability is largely due to this special cause. It is probable that most of us are not very zealous to prove the healthfulness of early rising; we are largely inclined to consider it rather as a necessary evil altogether aside from its unsanitary aspects, and the doctor's theory will be an acceptable one to a large majority. Whether it is well founded or not need not here be

seriously argued, but if it has no better foundation than the assumed greater prevalence of insanity in rural than in urban communities, it can not be said to be well supported. The statistics of American, and for that matter of foreign, asylums all indicate that the ratio of the insane to the population is far greater in the larger towns than in small ones or in country districts. Thus DR. E. B. LANE found, in discussing the Massachusetts statistics, that the proportion of insanity was twice as great in the city of Boston as it was in the small villages and rural districts, and that the ratio in the smaller cities was also greater, though less than in the metropolis of the State. Massachusetts is, however, so little of an agricultural State that it may be objected that its data hardly fairly represent the true ratio, and it is as well to take the statistics of those institutions that draw their inmates largely from a farming community. There are some of these that carefully classify their admissions, according to occupations, as well as according to rural or urban residence, and these afford some data for estimating the relative frequency of mental disorders in the agricultural population. Assuming these to be reliable, and there is no good reason for doubting them, we find that even in a State like Iowa, covering a period of over thirty years, during a large part of which the proportion of urban population was small, and which is yet very largely an agricultural community, the farmers and farm hands furnished less than a third of the insane male inmates of the chief asylum of the State. If we take other similar regions the testimony is the same, and when the wives and daughters of farmers are specified as such, their ratio in the asylums is not disproportionate to that of the males. In fact the statistics that are available indicate that the exact reverse of the popular notion, for such it seems to be, is the truth. Physical and mental degeneracy are more the characteristics of crowded centers of population than they are of the comparatively healthy country districts. The general mental and physical sanitary conditions in country dwellings and their surroundings are often bad enough, but there is not the concentration of untoward influences that exists in the cities, and the result is the better for the race. It would not seem needful to point out or emphasize these facts but for the notion that seems to be largely abroad that farmers are specially liable to insanity. It is not a teaching of the psychology manuals and monographs, nor is it held to any extent by those who from practical experience and study are best able to estimate the causes of mental disease. A number of years ago a prominent asylum superintendent called attention to the monotonous and laborious lives of farmers' wives as conducing to insanity of certain kinds, but he probably did not intend to convey the idea that they furnished any extremely large proportion of the insane. His statements, how-

ever, were reproduced and commented upon again and again in the lay journals, and it is to this in all probability that we owe the rather widespread delusion, for such it has come to be, which has been noted above. The increase of insanity in this and in other countries at the present time goes parallel with the increase of urban population at the expense of the country districts, and there is no valid evidence that agricultural pursuits and country life are in any way in themselves expressly conducive to mental disease. The belief that it is, the expression of which we see from time to time in the lay press and even as above indicated occasionally in medical journals, is due to the misunderstanding and misapplication of what was at best only a partial and rather one-sided observation, which may have been correct under the particular circumstances, but which has no general or universal application.

TRICHOMONAS AS A PARASITE OF MAN.

Trichomonas belongs to the flagellate infusoria. **BUETSCHLE**¹ says that about three species of Trichomonas are known. All are parasitic, living in the intestines of frogs, snails and other lower animals, and in the human vagina. Trichomonas vaginale was found in the vaginal secretions of women by **DONNÉ**² in 1836. While **DONNÉ**'s observations, though at first criticised, were finally accepted as true, yet it may be said that the parasites have been deemed of so little importance that they have until very recently received only scant notice.

Dock,³ of Ann Arbor, has just published a careful review of the literature bearing on this parasite in connection with the report of an extremely interesting case in which the trichomonas was found in the urine of a man. **Dock**'s case seems to be the third undoubted case of this kind in the order of publication, and the first in this country. **MARCHAND**⁴ described the first case in which the host was a man, aged 60 years, who had a perineal fistula following suppuration in the pelvis. Pus appeared suddenly in the urine, in the sediment of which **MARCHAND** found numerous hyaline bodies, which proved to be flagellates. A very short time after publishing his own case, he received from **Dr. MIURA**⁵, of Tokio, an account in manuscript of a second case in which trichomonads were found in the urine of a man, aged 52. In this case the organisms came from the urethra. Similar flagellate organisms were found in the vaginal secretions of the patient's wife and thus the source of infection became reasonably clear.

Dock's⁶ case occurred in a man, aged 27, who had been suffering with frequent urination ever since 1884, at which time he had a "congestive chill"; he

was then living in Texas and was frequently attacked with malaria. In 1892 he had pneumonia and during convalescence painful and frequent urination was marked, the urine becoming very bloody. The bleeding soon ceased but dysuria continued, exacerbations occurring at irregular intervals. At the end of urination whitish particles are passed with the urine. When examined by **Dr. Dock** caseous-like bits were observed in the urine made up of pus corpuscles, bladder epithelium of all kinds, and a number of animal parasites which were subjected to careful and repeated study with the result that they were determined to be trichomonads. In size the parasites were found to vary from 15 to 22 m.m. in length and 10 to 15 m.m. in width. The typical form is a pyriform or broad spindle with one end rounded. The outlines are usually sharp, the structure finely granular, sometimes hyaline, rarely coarsely granular. A differentiation into ecto- and endo-plasm can usually be made, the inner layer having a finely vacuolated appearance when examined by high powers. The parasites were hard to stain; killed by sublimate in methylen blue solution or stained alive in acetic carmin, a nucleus appears which can not be seen in unstained preparations. In acetic carmin the nucleus appears as a long, narrow, somewhat irregular body about one-fourth to one-third the length of the organism. At the anterior end of the parasite are the flagella which are four in number and from one to three times the length of the body. Often the posterior end of the body is prolonged into a long tail-like process that seems to be due to a soft pseudopod, which is frequently adherent to various neighboring objects. In many organisms an undulating membrane is present that extends from the insertion of the flagella backward usually for about two-thirds of the body. **Dock** did not find any sign of a mouth or other digestive organs.

Among the physiologic characteristics of the parasite may be mentioned motion, the phenomena of which are very interesting. Parts of the body may contract, lobes may be projected, but truly characteristic ameboid movement is not present. Pseudopods may form and move at any part of the body. These pseudopods seem to act as organs of support, the animal making abrupt, rapid, bobbing movements resembling that of a duck diving for food, the flagella and membrane being then in active motion. The flagella are capable of a whip-like motion, but may also present moving spiral waves. In an incubator the parasites were found to remain alive for six to seven hours; at room temperature they die an hour or two earlier. The organisms occur only in acid urine. Efforts to cultivate the trichomads anaerobically failed. Animal inoculations also failed.

Reproduction is regarded as occurring by longitudinal division in all flagellates. The mode of infec-

⁶ Loc. cit.

tion is not known. In Dock's case the facts point to an indirect entrance into the urinary tract.

Have these organisms any pathogenic powers or are they simple "commensals?" DONNE⁷ thought the trichomonas vaginale characteristic of vaginal blennorrhagia, but later he concluded it had no specific importance. SCANZONI and KÖELLIKER⁸ did not believe the parasites had any pathogenic power. The prevalent opinion among recent writers is that the organisms in the vagina are "commensals." The intestinal parasites of this group can, it is thought, keep up a diarrhea. EPSTEIN⁹ shows that some of the intestinal flagellates can produce diarrhea.

In MARCHAND's and MIURA's cases the flagellates were associated with bacteria, but in Dock's case the conditions were simpler. In his patient the process was distinguished by an exudation of leucocytes and epithelial desquamation without any sign or history of stone and no evidence of any bacterial infection. The urine was invariably sterile as regards bacteria. The conclusion consequently seems warranted that the parasites produced the anatomic alterations. The hematuria which was present in Dock's case shows that trichomonas can not be left out of consideration in future investigations of this important subject, concerning the malarial nature of which there is always much discussion in our malarial districts.

INSIGNIA OF THE MEDICAL DEPARTMENT U. S. A.

The board of officers of which COLONEL CHARLES H. ALDEN, Assistant Surgeon General, U. S. A. is president, convened some time ago to consider and report on the insignia of the Department to be worn on the shoulder knots of the full dress uniform and on the collar of the fatigue blouse instead of the shield in gold worn at the present time, has concluded its labors and rendered its report and recommendation to the Surgeon General. The board called for suggestions from medical officers of the Army and of the National Guard, all of whom showed the greatest interest in the subject. Many in reply sent drawings of their views of the appropriate insignia, and not a few forwarded their propositions in gold embroidery on dark blue cloth or braid. The board was at first embarrassed by the multiplicity of the suggestions; but on careful consideration it was found that about ninety per cent of the replies were in favor of a cross as opposed to any other devices, and a larger proportion called for a cross in gold or in gold embroidery than for the Red Cross of the Geneva Convention which is worn upon the arm brassards in times of war. As expressing the views of the majority the board decided on recommending a cross, differing somewhat from that of the Knights of St. John, of the accompanying form, seven-eighths of an inch

over all, in dead gold bullion with plain center. It is understood that SURGEON GENERAL STERNBERG has

Seven-eighths inch over all; dead gold bullion, plain center.

approved the report of the board and submitted its recommendations to the SECRETARY OF WAR. On the approval of this functionary the cross will become the regulation insignia of the medical officers of the Army. The Medical Departments of the National Guard will no doubt remodel their insignia, and in progress of time this cross will have as intimate an association with the military surgeons of modern times as that of Malta has in history with the Hospitaller knights of nine hundred years ago.

THE ATLANTA MEETING.

The members of the ASSOCIATION will find the Annual Announcement of the Permanent Secretariat in this issue. Every indication points to a large and successful meeting. Gentlemen from the Northwest attending the meeting will find it pleasant to join the JOURNAL special train, which will leave Chicago March 3, arriving in Atlanta Monday afternoon, May 4.

CORRESPONDENCE.

Concerning Lombroso.

BRECKENRIDGE, MO., February 20, 1896.

To the Editor:—Having carefully read your editorial "The Italian School of Criminal Anthropology," in the JOURNAL of February 15. I can not resist the impulse to write you a few words of congratulation for your able and elaborate defense of Professor Lombroso and his modern science of criminology. The Italian professor, as the founder of the new science of criminal anthropology, has been severely criticized by many of our alienists and optimists of religion and science but it was not surprising that the views he enunciated, relating to problems of no ordinary difficulty and complexity, should meet animadversion and strictures, even among our thoughtful men. You are doubtless correct in saying, "that much that is felt by excellent men on this subject is prejudice (if the word is not too severe) springing from a superficial knowledge of the works of the Italians themselves and their coadjutors in France and Germany." Prejudice is the first-born of ignorance and never outlives its father. Professor Lombroso has taught us that the criminal is worthy of study and almost everybody, at the present time, is at least in accord on that point that he is an abnormal person, both mentally and physically, whose responsibility should be considered from another point of view than that to which we had been accustomed in former times. In regard to these abnormal peculiarities of the criminal, the following terse and vigorous language of I. Elam ("A Physician's Problems") meets with my hearty

⁹ Prager Med. Wochenschrift, 1893, Nos. 38, 39, 40.

proval: "I do not hesitate to say that these constitutional defects may be (and *daily are*) so combined as to produce almost complete irresponsibility under a rational system of judgment; even in cases where the intellect, *such as it is*, remains coherent, and its possessor is accounted sane. Hence arises, in great measure, that strange insoluble problem of our race, the existence of what are called the 'Dangerous Classes,' a people who seem set apart to fill our jails, our penitentiaries, our houses of correction, and penal settlements; a people at war with their kind, natural enemies of their brethren; a leaven leavening, and infecting and drawing into the vortex of its own corruption even the comparatively sound elements of society; the pariahs of humanity, the despair of philanthropists, the approbriums of legislation. It will not be by constantly repeated corrections that these classes will be reformed—'Why should ye be stricken any more? Ye will revolt more and more'—but by a patient repetition of the means by which man as a race, has been civilized." This new conception of the criminal which is in a fair way to change our ideas and customs regarding criminal justice, is due almost entirely to the agitation provoked by Professor Lombroso and his pupil, Dr. Max Nordau, by his celebrated work on "Degeneration." The readers of the JOURNAL are under many obligations to you not only for your many valuable editorials, but for the many important improvements in it during the last year.

Yours truly,

M. BOTTOM, M.D.

Has Edson Scooped the Record?

TECUMSEH, MICH., Feb. 18, 1896.

To the Editor:—The following clipping is taken from the Detroit Free Press and certainly speaks very plainly for itself:

"TO PHYSICIANS IN REGULAR PRACTICE will be sent free by mail a sample bottle of Dr. Edson's Aseptolin, the new discovered treatment for consumption, etc., together with Dr. Edson's paper, reprinted from the New York Medical Record of Feb. 8, 1896. Those who have patients suffering from consumption are urged to test this remedy. None but physicians can use it. Address, etc., etc."

We are living in a decidedly fast age.

Respectfully,

J. F. JENKINS, M.D.

Information Wanted.

DETROIT, Feb. 25, 1896.

To the Editor:—Will you kindly inform me through the JOURNAL what the requirements are for the practice of medicine in Minnesota? If there is a State Board, and the address of the Secretary? How often and where the examinations are held? You will greatly oblige your reader,

297 Brush Street.

R. Y. FERGUSON, M.D.

NEW INSTRUMENTS.

A NEW BLADDER IRRIGATOR.

BY J. M. G. CARTER, M.D., PH.D.
WAUKEGAN, ILL.

The instrument here described was prepared to meet the requirements of some cases of vesical catarrh. The simplicity of the apparatus is its chief feature, yet it meets all the indications where douching or washing out the bladder is desired. It consists of an ordinary No. 9 metallic catheter, jointed, so that a male or a female point can be attached as required. The points are perforated to facilitate the inflow and outflow of the water used in the douche. Near the end of the stem is a reflow-pipe, as indicated in the diagram. It is thus used: The irrigator, 1, in diagram is introduced into the bladder, 2; a fountain syringe, 3, is filled with the solution the physician wishes to use and the tube, *a*, attached to the irrigator. 1: a rubber tube, *b*, is attached to the reflow pipe, 4, and passes to a vessel under the bed. The rubber tube, *b*, is closed by the

pressure of the fingers or by a clip like those used on the tube of an ordinary fountain syringe tube; the tube, *a*, is opened by removing the pressure, and the fluid flows into the bladder. When the viscus is full, tube, *a*, is closed and tube, *b*, opened. In this manner by refilling and emptying the bladder as thorough washing as is desired in catarrhal and calculous condi-

tions can be quickly and easily accomplished. The fluid in this method touches all parts of the vesical wall. The degree of pressure can be readily controlled by elevating or lowering the fountain bag, and the same act will control the effect of the impact of the water on the wall of the bladder.

The instrument is made by Sharp & Smith, 73 Randolph St., Chicago.

PUBLIC HEALTH.

Camel's Flesh for Paris.—The Algerian butchers, says the *Petite Republique*, of Paris, have made a contract with two Paris houses to supply a large quantity of camel's meat, which will be sold in the capital during the carnival time. According to the official report of the Algerian sanitary inspector, the meat resembles that of the ox, but is not so fine in its fiber. It is as tender and as nutritious as veal. The camel's hump has been esteemed by the *gourmet* as an especially dainty morsel, so toothsome as to cause regrets when the last mouthful is eaten.

Preventive Vaccination of Cattle.—Prof. Hutyrá's report on the diseases among cattle in Hungary during 1894, is a grand testimonial in favor of preventive vaccination in epizootics. The mortality from the anthrax diseases has fallen from 5 per cent. in cattle to 0.024 per cent. and from 10 per cent. to 0.032 per cent. in sheep. Swine plague is the special scourge of the Hungarian farmers, and they are correspondingly elated to find that preventive vaccination has reduced the mortality from 20 per cent. to 0.28 per cent. in hogs. Six hundred and eighty-one thousand one hundred and eighteen hogs were vaccinated, 222,684 sheep and 110,739 heads of beef.

Rabies in England on the Increase.—According to a report quoted in *Public Health*, rabies became very prevalent in England in 1889, particularly in London and the surrounding counties, and in the more densely populated parts of Lancashire, Yorkshire and Cheshire. During that year no less than 312

cases among dogs were reported to the authorities, but, so soon as suitable muzzling regulations were brought into operation, the number of cases suddenly fell, until in 1892 only 38 were reported. In January 1894, nine cases among dogs were reported. The number became larger month by month, until it amounted to thirty-four in November and fifty-eight in December. The total for the year was 248, against 93 in 1893, and 38 in 1892.

Reform in Match Factories.—The French government has appointed a committee to investigate the subject of matches, in the attempt to discover a substitute for the white sulphur now used, which is so injurious to the workmen. There would be no injury from the use of this substance if the public would consent to use what is called the "Army" or "Swedish" match, which will only ignite on a special surface. It is the combination of chlorate of potash with the white sulphur that is so injurious, and in this match, the two substances are kept separate, the chlorate in the match and the phosphorous on the igniting surface. Red phosphorus makes matches which ignite from the slightest friction and burn out inside the boxes, while white phosphorus will not burn without air. The committee appeals to the inventors and manufacturers of the world to join in this attempt to evolve a perfect match with no injurious effects upon the workmen. The *Bulletin de la Soc. de Pharm.* of Bordeaux, December, 1895, contains the detailed account of the committee's experiments with different substances.

Quarantine Disinfection in New York Harbor.—Dr. A. H. Doty, the health officer of this port, has devised a plan for disinfection which has been highly recommended by the national health officers and will be put into operation when a bill appropriating \$6,000 for the purpose has been passed by the legislature. It provides for the only floating disinfecting plant in the world, and is calculated to do away with the long delays which are common in disinfection, besides being much more thorough than the present methods. When Fire Island was purchased by the State a few years ago at the time of the cholera scare, a steamboat was bought, and Dr. Doty has recently taken her to quarantine, with the view of utilizing her on his new plans. When the steamboat is ready for use, she will steam out to any ship where disinfection is necessary and make fast. The sailors and passengers will be transferred to her, and the work begun at once. The entrance to the disinfecting quarters will be in the afterpart of the boat, there being a little corridor with a door on each side, the women using the entrance on the left, and the men that on the right. In the two rooms they will remove all of their clothing, which will be placed on a tray, which will be run into a heated chamber where the temperature will be raised above 220 degrees, and remain there for an hour. In the meantime the owners of the clothing will go into bathrooms, where they will get a shower of salt water, followed by a plunge in fresh water, all of which will take about ten minutes, after which pajamas will be furnished to the men and woolen gowns to the women, and they will wait the rest of the hour for their clothing. After dressing they will go on deck to await the disinfection of the ship bedding, etc., which is to be carried on at the same time: the bedding being placed in the heated chamber on steamboat, and the ship being washed down with bichlorid of mercury solution, and smoked with the fumes of burning sulphur. It is expected that all this work can be done in a few hours with a ship of moderate size, and that in any case the delay will not be more than two days.

Mortality of New York State in 1895. By a summation of the twelve monthly bulletins of mortality, published by the State Board of Health, the very large total mortality of 121,735 is arrived at for the year. This is 3,500 more than in 1894, but less than any previous year since 1890. Delayed returns not recorded in the Bulletin, to the number of 4,500 deaths, make

the actual reported mortality for the year 126,235. The estimated reported population is 6,650,000 which makes a death rate for the year of 19.00 per 1,000 population; in 1894 it was 18.75; in 1893, 19.50; in 1892, 20.78; in 1891, 21.43; and in 1890, 19.65. There was an average daily mortality of 336, against 324 in 1894, and 340 in 1893. The Maritime district had a death rate per 1,000 population of 21.20; the Hudson Valley, of 18.70; the Mohaw Valley, the East Central and the Lake Ontario and Western districts, each of about 15.50, while the other more sparsely settled and perhaps not fully reporting districts have a rate of from 12.00 to 13.40 deaths per 1,000 population. The mortality under the age of 5 years was 34.5 per cent. of the total; for the past six years this has varied from 31.6 to 38.6. In the summer months 45.5 of the deaths occurred in early life; in the spring 33.1; in the fall 29.5; and in the winter 28.7. The zymotic mortality constituted 16.55 per cent. of the total during the year: in 1894 it was 18.56 per cent. and in preceding years it has been from 17 to 20.60. Typhoid fever caused 1,720 deaths, about 25 per 100,000 population, which has been the rate for several years past. The Hudson Valley district has a higher rate of mortality from it than any other. Diphtheria caused 5,000 deaths, which is less than for several years. Its decrease occurred in all parts of the State, but chiefly in the maritime district where there were 1,200 fewer deaths from it than in 1894. Scarlet fever caused 850 deaths, which is less than half the average yearly mortality from it for the past eight years. From measles and whooping cough the mortality was excessive, and especially in the eastern part of the State, but becoming more generally distributed in the last of the year. Diarrheal diseases caused 9,000 deaths, which is, with little variation, the yearly average in this State. There were 546 deaths reported from cerebro-spinal meningitis, and 406 from malarial diseases, the latter showing a yearly decrease in reported mortality for eight years. From grippe there were 5,100 deaths in the four first months of the year. Consumption caused the usual yearly mortality, a little over 13,000 deaths, and a little more than 10 per cent. of the total deaths.

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Arizona: Hirschaw, February 17, 10 cases.
Illinois: Cairo, February 15, 1 case.
Louisiana: New Orleans, February 8 to 15, 18 cases, 1 death.
Michigan: Detroit, Ionia Township, Imlay Township, Rega Township, Saginaw Township, week ended February 14, small-pox reported present.
New York: Brooklyn, February 15 to 22, 1 case.
Pennsylvania: Finleyville, February 11, 1 case; Gilberton, February 13, 1 case; Maltby, February 17, 1 case; Brookville, February 18, 1 case.

SMALLPOX—FOREIGN.

Alexandria, January 15 to 21, 2 deaths.
Cairo, January 15 to 21, 1 death.
Canton, February 1 to 8, 4 cases.
Corunna, January 25 to February 1, 3 deaths.
Guayaquil, February 1 to 7, 2 deaths.
London, Eng., January 25 to February 1, 74 cases.
Madrid, January 7 to 25, 16 deaths.
Montevideo, January 11 to 18, 1 case.
Nogales, February 8 to 15, 1 case.
St. Petersburg, January 25 to February 15, 15 cases, 3 deaths.
Southampton, February 1 to 8, 1 case.
Swansea, January 25 to February 1, 5 cases.
Taxpan, February 1 to 8, 2 deaths.
Warsaw, January 25 to February 1, 3 deaths.

CHOLERA FOREIGN.

Austria-Hungary: January 21 to 27, 1 case, 3 deaths.
Egypt: Alexandria, January 15 to 21, 7 deaths.
Russia: December 28 to January 4, 28 cases, 19 deaths; January 25 to February 1, 7 cases, 7 deaths; Kiev (government), December 15 to 21, 12 cases, 6 deaths.

YELLOW FEVER—FOREIGN.

Cuba: Sagua la Grande, February 1 to 8, 3 cases; Santiago, February 8 to 15, 7 deaths.

NECROLOGY.

JOSEPH JONES, M.D., LL.D.,* of New Orleans, La., February 17. He was born in Liberty County, Ga., in 1833. His father was the Rev. Charles Colcock Jones, D.D., a distinguished Presbyterian divine and author of "God." His maternal grandfather was Capt. Joseph Jones, of the "Liberty Independent Troop," who served in the war of 1812: his great-grandfather on the paternal side was Maj. John Jones, an officer in the Continental Army, who fell before the British lines around Savannah during the memorable assault in October, 1779, and himself connected with the Pickneys, Haines, Swintons and Legarés of the Palmetto State. His early education was in the main acquired through the aid of private tutors at the paternal homes, Montevideo and Maybank plantations, in Liberty County, Ga., and in 1849, when he was 16 years of age, he repaired to South Carolina College, at Columbia. Having completed his freshman studies in this institution, he matriculated at Princeton, in the sophomore class 1850. He received his A. B. diploma from that college in June, 1853. Dr. Jones subsequently entered the medical department of the University of Pennsylvania. Shortly after the award of his doctorate, in 1855, he was elected Professor of Chemistry in the Medical College of Savannah in 1856. In 1858 he became Professor of Chemistry and Geology in the State University, at Athens, and in the following year was called to the chair of Chemistry in the Medical College of Georgia, in Augusta. This office he retained during the period covered by the late war, except when interrupted by active engagements in the field. In 1866 he was tendered the professorship of Institutes of Medicine in the University of Nashville. His connection with that university terminated when he removed to New Orleans, in the fall of 1868. It was there his labors in behalf of the medical department of the University of Louisiana, now Tulane University, began. Dr. Jones was appointed visiting physician to the Charity Hospital of New Orleans, on his arrival in that city. His long service in this capacity has proved valuable alike to the State of Louisiana and to the cause of medical science. He was the chemist of the Cotton Planters' Convention, in 1860, and the compiler and author of the first report submitted to that body touching the agricultural resources of the "Empire State of the South." When the Southern Historical Society was founded in New Orleans, in May, 1869, he became the first secretary of that organization, the framer of its original constitution, and an intense friend of the movement which gave it birth. To his individual efforts the sustenance of its vitality in the infant stage of its history, was to a large extent due. The organization was subsequently transferred to Richmond, Va. The officers of the Southern Historical Society, as first founded in New Orleans, were: Rev. Dr. B. M. Palmer, President; Gen. Braxton Bragg, Vice-President; and Dr. Jones as Secretary and Treasurer. In April, 1880, Professor Jones was made president of the Board of Health of the State of Louisiana, which had been reorganized in accordance with the provisions of the State constitution of the preceding year. His administration of the affairs of the board were characterized by ability, fidelity and industry. In April, 1887, Dr. Jones was elected president of the Louisiana State Medical Society. He bore a prominent part in the deliberations of the Ninth International Medical Congress, which convened in Washington City, in the summer of 1887, and was president of the Fifteenth Section. Public and International Hygiene. In 1890 he was made Surgeon General of the United Confederate Veterans. Dr. Jones was commissioned surgeon in the confederate army in 1862. His duties as such ceased in 1865. For some months prior to receipt of his commission, he had regularly discharged the functions of the office to which he was afterward promoted. As early as January, 1861, he volun-

teered in the Liberty Independent Troop, and entered upon active service in October of the same year. During his connection with this cavalry troop he acted as surgeon to several kindred organizations doing duty on the Georgia coast.

Professor Jones was a member of leading medical and scientific societies, both in this country and in Europe. His chief claims to recognition rest upon his achievements in the field of original investigation, and upon his reputation as an authoritative and exhaustive writer. Omitting several minor publications, his first production was "Investigations, Chemical and Physiological, Relative to Certain American Vertebrata." It was comprised in the eighth volume of the Smithsonian "Contributions to Knowledge," and appeared in 1856. In the same year his "Physical, Chemical and Physiological Investigations upon the Vital Phenomena and Offices of Solids and Fluids of Animals" was given to the public. This was followed by his "Observations on Malarial Fever," in the *Southern Medical and Surgical Journal*, of Augusta, Ga., for 1858-59, and his

JOSEPH JONES, M.D., LL.D.

"Observations on Some of the Physical, Chemical, Physiological and Pathological Phenomena of Malarial Fever." These latter observations were published in Vol. xii of the Transactions of the AMERICAN MEDICAL ASSOCIATION. Subsequently appeared his "Suggestions on Medical Education;" "First Report to the Cotton Planters' Convention of Georgia on the Agricultural Resources of Georgia," (Augusta, Ga., 1860); "Investigations into the Diseases of the Federal Prisoners Confined in Camp Sumter, Andersonville, Ga.;" "Investigations into the Nature, Causes and Treatment of Hospital Gangrene, as it Prevailed in the Confederate Army" (New York, 1866); "Researches upon Spurious Vaccination in the Confederate Army" (Nashville, 1867); "Sanitary Memoirs of the War of the Rebellion" (New York, 1866-1868); "Molities Ossium" (Philadelphia, 1869); "Outline of Hospital Gangrene in the Confederate Armies" (New Orleans, 1869); "Surgical Memoirs of War of the Rebellion" (New York, 1871); "Observations upon the Treatment of Yellow Fever" (Louisville, Ky., 1873); "General Conclusions

*Abstracted from "Eminent Physicians" by R. French Stone.

as to the Nature of Yellow Fever" (New York, 1873); "Hospital Construction and Organization" (Baltimore, 1875), and "Explorations of the Aboriginal Remains of Tennessee," which was published by the Smithsonian Institution at Washington, in 1876. The last-named represents the author's principal contribution to the science of archeology. Articles and pamphlets discussing the modes of burial, burial caves, earth-works, mounds and relics of the Southern Indians have likewise been furnished by his pen. In the year 1876, appeared the first volume of his "Medical and Surgical Memoirs," containing investigations on the geographical distribution, causes, nature, relations and treatment of various diseases, and embodying results to the attainment of which more than twenty years had been devoted. The concluding volume of these memoirs dates its appearance since 1890. In the second volume are published Professor Jones' latter-day labors and researches, as recorded in a series of monographs, among which his "Physiological Principles of Education and their Scientific Application to the Development and Perfection of Medical Science," takes foremost rank. His observations and researches upon sanitary matters form a unique chapter in the medical history of an eventful period. During his presidency of the Board of Health the quarantine and sanitary measures instituted and perfected by Dr. Jones were effectual in excluding yellow fever from the Valley of the Mississippi. His last important work was published in the JOURNAL last year as a serial, and contains a vast amount of information of the subject of yellow fever, and an almost incredible number of original investigations. Dr. Jones was twice married. In October, 1858 he married Miss Caroline S. Davis, of Augusta, Ga. His marriage to Miss Susan Rayner Polk, a daughter of the Right Rev. Leonidas Polk, Bishop of Louisiana and Lieutenant-General in the Armies of the Southern Confederacy, occurred June 21, 1870. In the same year he went abroad, visiting England, France and Wales, and making a careful tour of the hospitals and museums of those countries. Professor Jones was an earnest student of American archeology and to his reputation as a writer on archeology he had the distinction of being an extensive collector. In times to come, his volume of memoirs, and his last work on yellow fever, will be referred to as a vast storehouse of information on the subjects treated. America has never produced a more earnest student, or a more painstaking and diligent scholar.

L. H. JOHNSON, M.D., died of neurasthenia on Thursday, the 30th ult. He was a well known physician and one of the most prominent leaders of the colored race of Detroit. The doctor was a successful practitioner, not only among his own race, but among those of German and Polish nationality. He was active politically, but never aspired to office. Until last month he was president of the Douglas Frontier League, a member of the Detroit Medical and Library Association, an Oddfellow, and a member of St. Matthew's Episcopal church. He was born Sept. 16, 1842, in Uniontown, Pa. Through his own efforts he worked up until he became a conductor on the M. C. R. R. He accumulated enough money to push himself through the Chicago Medical College, where he graduated in 1880, ever since practicing in Detroit. He leaves a widow and two sons, Dr. A. H. and W. E. Johnson.

ALEXANDER S. HUNTER, M.D., died at his home in Spuyten Duyvil, New York City, February 14. He was born at Conesville, N. Y., in 1839. He was graduated from the Albany normal school. He then became a trader in Albany and pursued the study of civil engineering. He then went to Great Barrington, Mass., and became professor of mathematics at the Sedgwick Institute. Then he came to this city and entered the New York University Medical College, from which he graduated in 1863, and at once entered upon his career as a physician, opening an office in Broome street. He became con-

sulting physician at the New York Dispensary. He invented Hunter's speculum, which has been much used. He also invented Hunter's forceps. In 1890 he was elected president of the New York County Medical Society. He was the first president to succeed himself since the organization in 1807. For six years he was chairman of the obstetric section of the Academy of Medicine. He was also a member of the New York Medical Society, the State Medical Union, the Neurological and the Medical Jurisprudence Societies.

JAMES E. NOYES, M.D., of Providence, R. I., February 16, aged 79.—C. H. Donaldson, M.D., of Sterling, Ill., February 13, aged 71.—John Howard Ripley, M.D., of New York, February 14.—H. J. Saunders, M.D., of Kingston, Ont., February 19, aged 49.—James A. Holman, M.D., of Pittsburgh, Pa., February 18, aged 38.—H. Newberry Hall, M.D., of Chicago, February 23, aged 32.—W. H. Dickie, M.D., of Lincoln, Neb., February 18, aged 83.

ASSOCIATION NEWS.

Railroad Rates to Atlanta.

PHILADELPHIA, Feb. 21, 1896.

To the Editor: I just received from the Southern Passenger Association a promise of a fare and a third, on the certificate plan. As this Association has charge of the lines in the locality where we meet, I presume that the others will agree to the same. All who go to Atlanta will pay full fare, and take a certificate of the railroad agent: this is signed by me at Atlanta and by the agent there, who will be at the place of our sessions, and on this a return ticket can be bought for one-third full fare. The AMERICAN MEDICAL ASSOCIATION is pledged to redeem any such in hands of those who were not the original purchasers, and the certificates are not good more than three days after adjournment.

Your truly,

W. B. ATKINSON.

For annual announcement see page viii.

MISCELLANY.

Where He Was Hit. A Baltimorean being injured, was asked if he was hurt near the pelvis. "Why, no," he said, "it was near the monument."

Prizes for Diligence. The late Dr. Duesterhoff, of Berlin, Germany, left in his will the sum of \$25,000, as a capital sum, the interest of which is to be used as an encouragement to diligence on the part of the medical students of the university. The half-yearly interest is to be paid as a prize to each of the two students, who, at periods six months apart, is approved as having been the most diligent student in his semester.

New York University Medical Department.—The medical faculty of this University has reported in favor of extending the course from three to four years. This action will probably receive the endorsement of the council at an early date, the medical faculty having essentially the entire control of and responsibility for reforms of this nature. It is not impossible that before three years have passed by, all the large medical colleges of New York city will have adopted the four-year system.

Abortion. On an appeal from a conviction of having committed an abortion which it affirms, the supreme judicial court of Massachusetts holds that the averment of pregnancy was in that State unnecessary. If, being alleged, it was necessary to prove it, it was not necessary to go further, and prove that the fetus, at the time of the defendant's acts, had vitality, so that in the course of nature it could mature into a living child. Even if the child had then ceased to have such vitality, pregnancy would not cease till the woman was delivered.

Hunting a Lost Ball. The Roentgen ray and the location of bullets brings to mind an old army story about a general officer, who having been wounded in the fleshy part of the leg, the surgeons made many incisions. At last growing tired and worn with pain, he asked if they were nearly through dressing his

leg. "I am looking for the ball," said the operating surgeon. "Why the devil did you not say so before?" roared the officer. "I have the ball in my pocket."

A New Thaumaturgic Physician in Germany.—The physician who is attracting thousands of patients from all over Europe at the present time is Herr Ast, the shepherd doctor, who lives at Radbruch. For a uniform fee of about 25 cents he diagnoses disease by examining a lock of the patient's hair. It is said that his clients wait patiently in line all day to see him, and often, when their number is large, until midnight.

Public Improvements in Mexico. We read in *Progrès Médical* of January 25, that the French Chargé d'Affaires at Mexico has supplied his home government with the detailed information relative to the great public works soon to be inaugurated in the City of Mexico and elsewhere. Among these an entire new system of sewers for the capital is contemplated. The officer asserts that the Mexican government would be pleased to have the French offer their assistance in the new enterprises.

Hemiplegia in Hepatic Lesions.—Levi has been studying reflex patellar action during the course of hepatic lesions. Normal in fourteen cases, in eight he found it suspended. He considers this paralysis due to the disturbance in the peripheral nerves which accompanies the lesion, and not to the lesion itself. In one case the right reflex action was exaggerated and in two cases suspended altogether. These facts can be explained by the edematous hemiplegia on the right side in hepatic disorders, described by Hanot.—*Gaz. Méd. de Paris*, January 25.

Paris Overcrowded with Medical Students.—There are 6,300 medical students in Paris this year, one-fifth of whom are foreigners. It is difficult to procure cadavers and the facilities of the amphitheaters, etc., are limited to 3,000. In order to relieve this congestion, all the foreigners who ask for their "Equivalence," which is almost equal to a baccalaureate, are informed that it is no longer granted except on the condition that the receiver will leave Paris and conclude his course in some other town or city. The French home students have been protesting most vigorously for some time against being crowded out by outsiders, to whom, they assert, special favors are extended, and further restrictive regulations may be expected. The foreign graduate is no longer allowed to remain and practice in France unless he becomes a naturalized citizen.

Should not Require Administration of Anesthetics. In a personal injury case where the defendant requested the court to make an order requiring the plaintiff to submit to an examination as to the condition of his arm, the latter consented that an examination be made in open court, provided no anesthetics or drugs or harsh methods were used. The physicians appeared to deem it necessary to administer anesthetics in order to make a complete examination. Under these circumstances the supreme court of Michigan holds, *Strudgeon vs. Village of Sand Beach*, decided Dec. 24, 1895, that the circuit judge was right in refusing to require the plaintiff to submit to the administration of anesthetics.

The Country Doctor in France.—The London *Lancet* contains an item illustrative of the trials of the country doctor in France. A young physician settled in a community whose paupers he attended for \$10 per annum. One night, soon after his arrival at this Eldorado, he received an urgent summons to visit a patient who lived at a distance of six kilometers from the village. On reaching the cottage it was then 11 p.m.; he found the doors closed and the lights extinguished. In reply to his knocks the door was opened by a sturdy peasant, who laughingly informed him that there was no illness in the house, but that his wife had wished to see if, when anyone was ill, he would come if sent for! The unfortunate medico since died from overwork. The following lines would not be without their relevancy to the unfortunate French country doctor, although

they were written for, and to-day are cut upon the tombstone of a Virginia physician:

"He started on his travels,
Many, many years ago,
For the place where life unravels,
And dividing waters flow:
So I hope he has reached the haven,
Where no Anchor ever drags,
And has landed safe in Heaven,
With his shiney saddle bags."

The Campaign of the French in Madagascar.—According to an eye-witness, the statistics of this expedition are: Killed by the enemy, 7; wounded under fire, 94; death from disease, 6,000; on the sick list, 15,000. The *Union Médicale* commenting on these sad figures recalls another similar expedition, when Gen. Leclerc left Brest in 1802 for Jamaica with 60,000 men, and the yellow fever killed 50,000 in four months. Of the 10,000 left only 300 ever saw France again, and they did not reach home for seven years later. Since this frightful disaster this century has not witnessed another of the kind until this Madagascar campaign. In 1802 the authorities responsible for it were more unfortunate than guilty, but in 1895 they were more guilty than unfortunate.—*Prov. Médicale*, January 11.

Arterial Pulse in the Saphenous Vein.—The *Jour. des Sc. Méd. de Lille*, December 14, reports a case of arterial pulse wave in the inner saphena, which it notes as a curiosity. A woman was being examined for a tumor in the lower abdomen, under the influence of chloroform, and in the obstetric position. Suddenly a wave-like motion was observed on the left limb, following the course of the saphenous vein, which had quite a varicose appearance, and feeling like a pulse to the fingers. It was evidently an arterial impulse, proceeding counter to the current in the vein. As no trace of cardiac nor vascular trouble had been discovered that could explain it, and as it ceased when the limb was in a horizontal position, the conclusion seems evident that the saphena and the artery must have been squeezed together so closely by the tumor and the position of the limb that the arterial pulse wave was communicated to the vein. It could be followed to the calf of the limb and even to the ankle, but never occurred again after that occasion.

Improper Answer of Expert.—In a personal injury case, a medical expert was asked to state, from his knowledge as an expert, the treatment and what would be the course of chorea in the plaintiff's case. The witness entered into a general discussion of the disease, the various causes producing it, and some of the possible ultimate results thereof. Nowhere did he state or intimate or express an opinion as to what the course of the disease would be in the plaintiff's case, or the probability or improbability of her recovery. On the contrary, his answer was confined to the possible effects attending the progress of the disease in general, and its probable duration, and the results that might ensue to some person or other afflicted with the disease, and those results dependent on the producing cause of the disease. This the general term of the city court of Brooklyn holds, in *Swenson vs. Brooklyn Heights R. Co.*, decided Dec. 13, 1895, was wrong. It improperly placed before the jury results that might ensue, future consequences that were possible, and on this account the court orders a new trial.

Record Not Admissible to Prove Sanity. In a criminal prosecution, where the defense of insanity is relied on, the supreme court of Indiana holds, *Naanes vs. State*, decided Jan. 10, 1896, that the record of the proceedings of an examination by a competent commission as to the sanity of the accused is not admissible to show that the latter was sane at the time of committing the alleged offense. The court explains that it may, in reason, be said that a person found upon the inquiry of a commission not to be a fit subject for admission to an insane asylum, may, nevertheless, be of such mental unsoundness as to have immunity from punishment for crime. Furthermore,

if the evidence of the witnesses as recorded in the proceedings of the commission, and whom the accused had no opportunity to cross-examine, should be held to be admissible against him upon the criminal charge, it would manifestly result in a denial of his right, upon his trial, under the constitution, to meet witnesses adverse to him "face to face."

The Present State of our Knowledge of Diseases of the Spinal Cord.

Dr. Obersteiner recently addressed the Vienna Doctoren-collegium on this subject, and reviewed the wonderful progress made since the sixties, when the text-books only listed five, and only discriminated between the gray and white matter, where we now distinguish seventeen components. We owe to Nissel and to Weigert's new staining method much of our better information in regard to the more delicate nerves. To Marchi's method is also due Schmaus' discoveries of the changes in degenerate nerve fibers. We have learned how hypnotism deadens organic pain by its stupifying action on the functional system. We know that there is no dividing line between diseases of the peripheral and central nerves, as Landry's disease, for instance, commences with the former and ends with the latter. He enumerates seven inflammatory and seven non-inflammatory primary diseases, with several secondary, and adds "etc." to each. Unfortunately our knowledge how to treat them has not kept pace with knowledge of their pathology. Suspension has proved beneficial in tabes, but not on account of the hyperemia it produces in the spinal cord, as was supposed at first, but owing to the way in which it stretches and loosens the nerve fibers. *Wiener klin. Rundschau*, January 26.

Pharmacy Law Changes in South Dakota. Section 4, chapter 132, session laws of South Dakota of 1893, headed "Who entitled to be registered as pharmacists," was amended in 1895, to read: "Any person of good moral character and temperate habits who shall pass a satisfactory examination before the State board of pharmacy shall be entitled to a certificate of registration as a licentiate of pharmacy." A law was also passed which provides that any regular graduate over 18 years of age who has received a diploma for the pharmacy course in South Dakota Agricultural College, and who has before or after graduation practiced pharmacy for one year under a regularly licensed druggist in South Dakota in a drugstore where physicians' prescriptions are compounded, shall, upon passing a satisfactory examination by the State board of pharmacy, receive from the board a license entitling him to practice pharmacy in any county of South Dakota: and said board shall grant said license to said applicant without unnecessary delay. Any person who has had one year's work in said pharmacy course and two years' work in an accredited drugstore, shall be entitled to a druggist's license upon passing a satisfactory examination before the State board of pharmacy.

Gas Asphyxiation Treated by Oxygen Inhalations. Before the Canadian Medical Association a case of the above description was reported by Dr. J. W. Shillington, of Ottawa. The principal point of interest, according to the *Montreal Medical Journal*, was in the prompt success following the administration of oxygen when other means were failing. An interesting point was the face becoming black during the inhalation, which he supposed was due to the increased quantity of carbon dioxid formed in the presence of oxygen and circulating in the blood. Dr. T. W. Mills did not agree with the explanation offered by the President. Some years before he had suggested the method of treatment used by Dr. Shillington, but experiments upon animals had shown oxygen to be more efficient than air in cases of asphyxiation. Dr. S. R. McKenzie related the account of a case of an old woman asphyxiated by illuminating gas, who was brought to the Montreal General Hospital in a comatose condition. The patient did not react to the Faradic current. After the forced inhalation of many gallons of oxy-

gen the patient revived in about four hours. About a year previously, Dr. McKenzie stated, a much more favorable case had been lost, a young man who died after twelve hours continuous treatment by artificial respiration and stimulants. He had no oxygen to give him, but he now kept over one hundred gallons and applied it with a nitrous oxid inhaling apparatus.

Prescriptions for Intoxicating Liquor in West Virginia.—Under section 7 of chapter 32 of the West Virginia Code, the supreme court of appeals of that State vs. Berkeley, decided Dec. 4, that if a physician gives a prescription to enable one to obtain liquor from a druggist as medicine, either stating that it is, or that he believes that it is, absolutely necessary as a medicine, and not as a beverage when he either knows, or believes, or has reason to believe it is not so necessary, or when he does not know it to be so necessary, he violates said statute, and is guilty of the offense it creates. The physician must act in entire good faith. It is his duty to examine and ascertain whether the liquor is absolutely necessary as a medicine. And where a prescription names a certain person as the one needing such liquor, when he does not need it, and the physician knows he does not need it: but the person so named is getting it for the use of another, the statute is violated, though that other person may so need the liquor as a medicine. The prescription must name the person for whom the liquor is prescribed.

Puerperal Tetanus; Argument against Vaginal Douches.—Drapier writes to the *Jour. des Sc. Méd.*, December 28, describing a case of typical and fatal tetanus commencing nine days after a successful confinement which was progressing rapidly to permanent recovery without the slightest difficulty or complication, and never a trace of fever. Antiseptic vaginal injections had been ordered, phenolized or boiled water, which were carefully administered by the woman's husband. His business brought him in contact with horses, and the tetanus bacillus must have been on his hands or finger nails, or was already in the chamber, which had a direct passageway communicating with the stable. The writer asserts that this case confirms his growing disinclination to vaginal douches after confinement, except in special cases. He quotes Pinard (*Jour. de M. et de C.*, July 10, 1895), who states that they are always useless and frequently a source of danger; also Lucas, Sebilleau and Champnière. All agree that except in special cases, retention of membranes or fetid discharges, they had better be omitted, especially in the country, where antiseptic precautions are so little understood. In the case above noted, the closest scrutiny failed to discover the slightest abrasion on the woman's body where Nicolaïer's bacillus could have infected her, which limited the local seat to the uterus.

"Disease" or "Bodily Infirmary" in Law.—An accident insurance policy excepted injuries, fatal or otherwise, resulting directly from "any disease or bodily infirmity." In an action thereon, the jury were instructed that they must accept the word "disease" as meaning some ailment or disorder of a somewhat established or settled character, some physical disturbance to which the insured was subject, and of which the attack that caused his fall was in some manner a recurrence; that a mere temporary disorder, that was new or unusual with him, arising from sudden and unexpected derangement of the system, though it produced or caused unconsciousness, would not be a disease, within the meaning of the policy, and would not exempt the insurance company from liability. This the supreme court of Iowa sustains. *Meyer vs. Fidelity and Casualty Co.*, decided Dec. 13, 1895. It says that it thinks the words "disease" and "infirmity" as used, mean practically the same thing, and should be given no broader meaning when used by an insurance company in a clause of its policy than they are given in ordinary speaking and writing. And, on principle and authority, if the disorder which caused the fall was temporary and unexpected, the injury was "violent,"

"external," and "accidental," within the meaning of these words as used in an insurance policy.

Unchastity and Credibility.—For a considerable time the rule permitting a witness to be impeached by proof of general reputation for unchastity was confined, in Missouri, to females. Then the supreme court of that State held, in two cases, that the rule applied alike to both sexes, and that such reputation might be shown to discredit a male as well as a female witness. Now, in the case of *State vs. Sibley*, decided Dec. 10, 1895, the court, with three justices dissenting, overrules those two cases and reverts to its original position. Especially in a case where the defendant's character for chastity is directly involved, does the court think that such evidence is inadmissible for the purpose of impeaching his character as a witness. It is a matter of common knowledge, the court goes on to say, that the bad character of a man for chastity does not even in the remotest degree affect his character for truth, when based upon that alone, while it does that of a woman. It is no compliment to a woman to measure her character for truth by the same standard that you do that of man's predicated upon character for chastity. What destroys the standing of the one in all the walks of life has no effect whatever on the standing for truth of the other. Quotations are made from *Bank vs. Stryker*, 3 Wheeler, Cr. Cas. 332, *Dr. Johnson and McCauley*, to substantiate this.

Not Attendance of Physician.—A mere calling at a doctor's office for medicine to relieve a temporary indisposition, not of a serious nature, or his calling at a person's home for the same purpose, the supreme court of Michigan holds, in *Plumb vs. Penn. Mut. Life Ins. Co.*, decided Dec. 30, 1895, can not be considered an attendance within the meaning of a question in an application for life insurance. To constitute an attendance, it must be for some disease or ailment of importance, and not for any indisposition for a day, or so trivial in its nature, such as all persons are liable to, and yet are considered to be in sound health generally. "Sound health," as used in the same connection, it is held, means a state of health free from any disease or ailment that affects the general soundness or healthfulness of the system seriously, and not a mere indisposition, that does not tend to weaken or undermine the constitution of the insured. Having had syphilis at the time of the application, constitutionally or otherwise, and denying it, or representing oneself to be of sound bodily health, will constitute a breach of warranty. Prescriptions appearing to be in a certain physician's handwriting are not admissible in evidence to prove that he treated a person for a certain disease so long as the druggist is unable to state that such person brought them to his drug-store to be filled.

Modified Privileged Communications.—The *American Medical Review*, January, has the following medico-legal novelty:

"The question of privileged communications to physicians has recently been before the court of appeals of New York in a new form; an interesting decision thereon has just been handed down. The case, that of *Morris vs. the New York, Ontario and Western Railroad Company*, came up on appeal, by the railroad company, from the general term, where the plaintiff had had a decision in her favor. Judge O'Brien, of the court of appeals, in his opinion, which was concurred in by the full court, and which reverses the decision of the lower court, holds, that when the plaintiff called one of two physicians who attended at the same examination, to prove what took place, or what he learned, the considerations and reasons on which was founded the statute against disclosure of facts professionally ascertained, no longer existed as to this particular case, and the plaintiff's act operated as a waiver of her right under that statute to object to the testimony of the other physician."

In this connection it may be added that a modified form of privilege will probably soon be put in operation in the courts at the capitol, for it is reported by the press agencies that Senator Morrill has introduced a bill in the Senate providing that in the courts of the District of Columbia no surgeon shall be permitted, without the consent of the person afflicted, to dis-

close any information which he shall have acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity, whether such information shall have been obtained from the patient or his family, or from the person or persons in charge of him; provided that this act shall not apply to evidence in criminal cases where the accused is charged with causing the death of or inflicting injuries upon a human being, and the disclosure shall be required in the interest of public justice.

Practical Notes.

Effects of Ouabain.—Gley reports to the C. R. Soc. de Biol., January 19, that less than 1-100 m.g. of ouabain is enough to produce in the frog's heart absolute systolic cessation of pulsation by the direct action of the poison on the heart. Strophanthin, we know, produces a similar effect. Ouabain has also a paralyzing effect on the spinal cord, and is, like strophanthin, a local anesthetic.—*Centralbl. für Phys.*, Oct. 5, 1895.

Pericarditis Accompanying Gonorrhea.—Blennorrhagia is frequently accompanied by pericarditis, commencing about six weeks after the former is under way. It does not last long and usually terminates by resolution. A writer in the *Progr. Médicale*, January 11, has been studying this subject and concludes that the pericarditis is not a secondary infection, but merely an extension of the gonorrheal processes, testifying to the important part played by Neisser's microbe and the close relation between the gonococcus and blennorrhagia.

External Antipyretics.—The substances used for this purpose are cocain, solanin, helleborin, spartein, or guaiacum, with which the skin is painted after first having been washed with soap and frictioned with alcohol. The most favorable surface for the application is the front upper part of the thigh. The solutions vary in strength, cocain and solanin at 1-20, helleborin 1-100 and spartein 1-20 only. Two to four grams are used at each application. *Revue Int. de Méd. et de Chir.*, January 25.

Local Treatment of Tuberculosis.—The *Gazette de Batkine*, 1894, No. 28, describes a case of pulmonary gangrene in a 16 year-old girl with a cavity on a level with the scapula, expectoration fetid and general condition serious. None of the usual remedies afforded relief, and finally an injection of 0.25 c.c. of iodoform was made into the cavity. Immediate relief ensued and general health improved. Twenty injections were made into the cavity, which decreased in size; patient lost her cough and gained in weight, and left the hospital very much benefited by the treatment. *Journal de Méd. de Paris*, January 19.

Mentholized Oil in Chronic Pharyngitis.—Fongueray writes to *Méd. Mod.*, Dec. 18, 1895, recommending the use of a 10 per cent. mentholized oil in chronic cases to relieve the cough and the sensation of a foreign body in the throat. He uses it: Menthol 1 gm.; oil of sweet almonds, 10 gm. The patient dips a water-color brush into this solution and paints the inside of his nostrils with it, throwing the head back and breathing deep. Then with an elbow-shaped handle and larger brush he paints the pharynx copiously with it reaching down as far as possible, and painting up into the nose.—*Revue Internat. de Méd. et de Chir.*, January 25.

Effect of Strychnin on the Pulsations of the Heart.—Meyer's experiments with dogs in 1871 convinced him that the sulphate of strychnin retards the action of the heart through its influence upon the moderating center of the spinal cord. Löwit and Richet, since then, reported as their conclusions from a series of experiments on frogs and dogs that the effect of a powerful dose was to annul the influence of the pneumogastric nerve on the heart. Lahousse writes to the *Arch. de Pharmacodynamie*, Vol. 2, No. 1, that he has been experimenting recently with the same animals to settle the question more definitely, and he finds that a 1 to 1,000 solution of sulphate of strychnin applied directly to the heart prolongs the diastole

and thus makes it pulsate less frequently. Careful study of all the phenomena produced lead him to assert that the action of the strychnin in retarding the rhythm of the heart is due to its effect on the intracardiac motor centers. *Nouveau Remède*, January 24.

A New Reaction for Antipyrin and Quinin. Professor Carrez writes to the *Journal des Sc. Méd. de Lille*, Dec. 14, 1895, in regard to a new reaction of antipyrin and quinin, resulting in a red coloring matter which he calls quinerythropyrim. It is made by adding *eau de brome* to a dilute solution of antipyrin and a quinin salt, until it assumes a slight yellowish tint, then adding ammonia, and the red color is obtained. The same process with quinin alone produces green. It can be taken out of the ammonia and water solution by shaking it up immediately with chloroform, in which it easily dissolves, as also in alcohol, but not in pure water. Acidulated water dissolves it readily and also frees it from the chloroform solution. Acid solutions of the new red produce an orange pink; alkaline solutions, a violet pink. Spectroscopic tests show that it allows all the rays to pass except the green ones. This reaction will be found a useful test to discover antipyrin in the urine, and in toxicology in general as well as in pharmacology.

Sambucin as a Diuretic. The *Journal de Méd.*, Jan. 19, 1896, remarks that in our enthusiasm over the new remedies, we are neglecting the vegetable medicines which often prove best after all for certain purposes. Lecocq has been experimenting with the *sambucus nigra*, whose reputation as a diuretic has been in eclipse lately. Lemoine found that the diuretic properties were in the innermost bark and that it lost them as it became less fresh, so he always ordered fresh bark, a handful boiled in a liter of water, of which the patient took from half a liter to a liter and a half during the twenty-four hours. Lecocq uses the ordinary syrup extract, prescribing 10 to 15 grams a day. According to the formula, this is equivalent to 10 to 15 grams of bark. Administered in this way it supplements the diuretics now in use: it is safe, agreeable, and can be continued a long while. It increases the appetite and also the digestive power. It may supplement advantageously caffeine and digitalis and has been known to succeed where the former failed.

Radial Paralysis of the Brachial Plexus.—*L'Union Médicale* of January 18 contains a careful study of this subject with a review of what investigators have contributed to our knowledge of it; prominent among whom are Klumpke, Duchenne and Erb, and quite recently Raymond. The differentiation is often difficult, as seven other troubles present somewhat similar symptoms. The apoplectic variety is usually followed by incurable atrophy. The reflex always persists a long while, with recovery doubtful. The variety caused by laceration or section of the plexus, is incurable, but obstetric paralysis usually passes away. The treatment is of course first to discover and remedy the injury to the nerve. Revulsion is often useful in paralysis of apparently spontaneous origin, especially if used promptly. But the one main reliance is electrotherapeutics. It requires perseverance for months at times, and this is the *sine qua non* of success. The electric treatment must not be limited to the nerve, but applied also to the muscles to restore their contractility and retard the reaction of degeneration, while favoring their nutrition, as they undergo rapid dystrophic changes when no longer under the control of their trophic centers.

Symptomatic Paroxysmal Tachycardia. Desplats had a patient come to him at intervals during the last two or three years, with every clinical indication of paroxysmal tachycardia, which were each time relieved by digitalis. The man had worked for twenty three years for the same firm without ever losing a day before he first applied for treatment, and he had no bad habits. The last time he came to the hospital, he died in a couple of hours, without speaking. The necropsy showed that death had been caused by acute pneumonia, but the heart and pleura had

grown together in such a way that at each systole the heart had to drag the neighboring organs along with it; a case of true mediastino-pericarditis. There were also evidences of an old endocarditis and abnormal adherences in the abdominal region, and also around the stomach, in which a cancer was found, as large as the palm of the hand. With all these lesions, the clinical picture was that of typical paroxysmal tachycardia, which is *not* relieved by digitalis as this case was. Desplats suggests that digitalis may thus be found valuable to differentiate symptomatic from true tachycardia.—*Journal des Sc. Méd. de Lille*, January 11.

Modern Treatment of Metritis.—Douriez has just published a work with this title, which the *Jour. des Sc. Méd. de Lille*, Dec. 28, 1895, commends and quotes as follows: In acute cases, absolute repose in bed, "as for a fractured thigh," vaginal irrigations; if blennorrhagic, dilation of the uterus and iodoform pencil or swab; if puerperal, scraping (Pinard) or continued intra-uterine injections (Budin); if chronic, copious vaginal douches for three days, mechanical dilation of the uterus for five or six days; cleansing of the uterine cavity and insertion of a large drainage tube, size of a thumb. This is removed a few minutes every other day to make an application of iodine inside the uterus. After three of these applications have been made the drain is removed and replaced by a vaginal tampon left for four days. This treatment lasts for twenty days, when the patient may leave her bed. Any special treatment indicated by the neck of the uterus or the pelvic basin must be studied also.

Treatment of Chronic Gonorrhea in the Male.—To prevent an acute attack of gonorrhea from leaving an inflammation of the urethra which may become chronic, Janel aborts it in the acute stage with potassium permanganate. The parts should be thoroughly cleansed with this to remove all the gonococci and prevent any secondary infection. To ensure the latter a dilute solution of sublimate should also be used. Superficial and fresh lesions in the bladder should also be treated with careful washings, and also with a solution of nitrate of silver administered a drop at a time. Not until this has been done and the infective germs thus destroyed, is it proper to commence the instrumental examination. Superficial and fresh lesions of the urethra and bladder are treated with washings, etc., as above; deeper and old lesions with dilatation besides; localized inflammations with the urethral endoscope. Both parts of the urethra must be treated, even when only the penile portion shows any lesions. —*Ann. des Mal. des Org. g. u.*, No. 6, quoted by *Centralbl. f. Chir.*, Jan. 25, 1896.

Serum Treatment of Erysipelas. The official report of the erysipelas hospital at Paris for the past year, is an interesting contribution to our knowledge of serotherapeutics. Patients were treated by different methods, but the percentage of cures was very much larger with the serum treatment. When the supply of serum ran short, the cures grew less. When an abundant supply was on hand the mortality fell to 1.03 per cent. Total number of patients treated, 1,055; with serum, 501. Large doses of serum proved most effective; one patient with purulent pleurisy had 300 c.c. injected in a fortnight without the slightest inconvenience from its use. The average dose is 20 to 40 c.c. and the beneficial results are directly proportionate to its preventive strength. The general health improves after first injection; delirium and nervous symptoms disappear; fever rarely persists as long as two to three days; pulse grows at once less rapid and stronger; if albuminuria is not present it does not develop, and it is cured where it exists, in forty-eight hours at farthest. Small doses of the serum, when a relapse threatens, prevent it in many cases.—*Rev. Internat. de M. et de C.*, January 25.

For and Against Antipyretics. The last meeting of the Paris Société de Thérapeutique was enlivened by a discussion of the

value of these remedies. One member announced that Charrin's recent experiments tend to show that it is best not to combat the fever, at least in septicemia, as it helps the organisms to resist the intoxication. Others recounted Richet's recent experiments, which seem to prove the reverse, viz., that by lowering the temperature the animal could support much larger quantities of poison without intoxication than at the normal temperature. Weber responded by the experience obtained from injecting artificial serum in certain peritoneal troubles which depress the temperature below normal. The injections brought it back to normal and above, and the patient is saved. Some believed with Charrin that antipyretics have a pernicious effect on the vital processes of the cells. Vogt mentioned that he had obtained the maximum of antithermic results with the least possible chance of toxic complications, by the use of the following:

R Antipyrin.	2 50
Phenacetin	1
Acetanild.	50
Misce.	

To be made into eight powders. Four to be taken in one day as largest amount.—*Revue Internat. de Méd. et de Chir.*, January 25.

Apparent Cure of Phthisis Treated by Neurotic Remedies. In the *University Medical Magazine*, December, Dr. William Pepper reports a case of phthisis, the treatment of which was signalized by a complete omission of all purely routine pulmonary medication, and by the apparently satisfactory result. Strychnin nitrate (1-100 of a grain) with atropin sulphate (1-1,000 of a grain), was administered every two hours hypodermically, together with strychnin nitrate (1-50 of a grain) and the double chlorid of gold and sodium (1-12 of a grain), by mouth every two hours. After a few days the dose of the latter was increased ($\frac{1}{8}$ of a grain). Egg albumin was well borne and this was increased until two dozen eggs (whites) were consumed per day. Cod-liver oil inunctions and passive massage were employed once daily. When the patient showed signs of strychnin intoxication the dose was reduced. Dr. Pepper's conclusions are summed up by himself thus: "The notable points in this case are: The sudden onset, quite like general miliary tuberculosis; the large number of bacilli; the rapid recovery, all the more remarkable with a pronounced tubercular family history; the complete disappearance of consolidation and bacilli; the acute reappearance after two years of the whole train of symptoms, with signs in the base of the left lung directly following an attack of pneumonia located in that vulnerable part; the large number of bacilli and their early complete disappearance in the second attack; the abatement of the consolidating process, and rapid recovery of the general health after the second attack; the absence from the treatment of all cough-medication and antiseptics, and the large dose of strychnin nitrate and the double chlorid of gold and sodium, with which the system was kept literally saturated."

The Surgical Treatment of Retro-Deviations of the Uterus.—Augustin H. Goelet, M. D., in a paper upon this subject read before the State Medical Society and the Society for Medical Progress, New York, declared that displacements of the uterus demand more careful consideration than is usually accorded them, and that the routine plan of inserting a pessary and dismissing the case from further attention is a serious error. He thought that the majority of cases, especially those of long standing where structural changes have taken place in the wall of the organ require surgical intervention for their cure. The pessary alone is not sufficient except in recent cases, because of the concomitant metritis and endometritis which must be overcome before a radical cure can be effected. After discussing the merits of Alexander's operation and the intraperitoneal methods of shortening the round ligaments and vaginal fixation he described a method which he had employed with success for

the past twelve years. The Alexander's operation which is only appropriate in movable retro-deviations is unnecessary, its chief disadvantage being the length of time it requires and the prolonged convalescence it entails. Where the uterus is fixed by adhesions he advocated opening the abdomen by means of a small incision and suspending it from the anterior abdominal wall, not fixing it. This was preferred to intraperitoneal shortening of the round ligaments because it consumes less time and it had given very satisfactory results. It is preferable to ventrofixation because the uterus is not fixed but movable. Vaginal fixation he thought objectionable because it substituted a fixed ante flexion for a movable posterior displacement. The recent unfavorable reports concerning complication during labor following it affords another very serious objection to this operation. The method of procedure which he advocated in place of Alexander's operation in movable retro-deviations, has this to recommend it, viz., that it aims at a cure of the coexisting metritis and endometritis, the maintaining cause of the displacement, and requires but a week's confinement in bed. In retroversion he dilates the canal, packs the cavity with iodoform gauze and tampons the vagina with the same gauze in such manner as to throw the uterus into a position of anteversion. This dressing is removed every day the cavity is washed out with a 1 per cent. solution of lysol and it is reapplied. This is done for a week and the patient is confined to bed. Then a vaginal pessary is fitted to hold the uterus in a correct position. The cavity is irrigated twice a week until a healthy endometrium is reproduced. In retroflexion the same procedure is adopted but instead of packing the uterus with gauze he uses a straight glass drainage stem which serves the purpose of a splint and keeps the uterus straight. It is then maintained in a position of anteversion by means of vaginal tampons of iodoform gauze. At the end of a week a vaginal pessary is inserted and the patient is permitted to get up. The success which he has obtained with this method leads him to believe that the other more complicated operations designed for movable retro-deviations are unnecessary.

Hospital Notes.

THE NEW ENGLAND Deaconess Hospital at Boston, Mass., was formally opened February 4.—An application has been presented for a charter for St. John's General Hospital, of Allegheny City, Pa.—The annual election of the Saturday and Sunday Hospital Association of St. Louis took place February 17.

Society Notes.

THE SIXTEENTH ANNUAL MEETING of the Atlantic County Medical Society was held in Atlantic City, N. J., February 5. The following officers were elected for the ensuing year: President, Philip Marvel; Vice-President, W. Blair Stewart; Secretary and Treasurer, Walter Reynolds.—A regular meeting of the Columbus (Ohio) Academy of Medicine, was held in that city February 17.—The annual meeting of the World's Congress of Medico-climatology was held in San Antonio, Texas, February 20, 21 and 22.—The annual meeting of the surgeons of the St. Joseph and Grand Island Railway was held in St. Joseph, Mo., February 20. The following officers were elected: President, Noah Hayes; Vice-President, Robert Dinsmore; Secretary, D. Morton, of St. Joseph.—The annual meeting of the Tennessee State Medical Society will be held in Chattanooga April 13. On account of the excellence of the program the largest attendance in the history of the society is expected.

Detroit Notes.

THE WAYNE COUNTY MEDICAL SOCIETY at its regular meeting Thursday, February 20, listened to a very interesting paper by George Andrew Lewis, entitled, "The Origin of Stammering." Mr. Lewis exhibited before the society sixteen patients which exemplified the methods of his teaching and the results.

AT THE REGULAR MEETING of the Detroit Medical and Library

Association held Monday, February 17. Dr. H. A. Gerry read a paper entitled, "The Gehrung as an Expedient."

HEALTH OFFICE report for week ending Feb. 22, 1896. Deaths under 5 years 35, total 98. Births, male 61, female 51, total 112. Contagious diseases: Diphtheria, last report 9, new cases 7, recovered 2, died 2, now sick 12. Scarlet fever, last report 12, new cases 5, recovered 2, died none, now sick 15. Small-pox, last report 5, new cases 5, recovered none, died 7, now sick 3.

Washington Notes.

WEEKLY REPORT OF THE HEALTH DEPARTMENT. From the report of the Health Officer for the week ended February 15, the following observations are obtained: A slight increase in the mortality of the city took place during the past week. According to reports received at the health department, there were 112 deaths, with an annual death rate of 21.13. In the corresponding period of last year, the deaths numbered 103, with a rate of 19.8. There were in the District, at the close of the week, twenty premises placarded on account of diphtheria. During the week twenty deaths occurred from this disease, twenty-one cases were discharged from quarantine, and eleven new cases were reported. Nineteen premises were placarded for scarlet fever, twelve cases were discharged from quarantine and eleven new cases reported. There were no deaths.

PUBLIC HEALTH MEETING.—A meeting of the Board of Trade was held on the 25th inst. The subject for consideration was the public health and sanitation of the city. Addresses were delivered by Drs. S. C. Busey, W. W. Johnston, Geo. M. Sternberg, U. S. A., J. J. Kinyoun, M. H. S., and others.

MARRIAGE LAWS IN THE DISTRICT TO BE AMENDED.—The Senate bill relating to marriages in the District has brought out much interesting debate on the diversity of marriage laws now in force here. Mr. Hoar offered an amendment forbidding marriages when one of the parties is an alien, unless a minister or consul representing the country of this alien certifies that the marriage is valid according to the laws of that country. Mr. Hoar said his purpose was to protect American women, attractive by beauty and accomplishment, from the rapacity of foreign adventurers, whether titled or untitled. The Senator cited instances of American marriages being repudiated in Germany when the parties returned there. Mr. Hoar's amendment was agreed to, also one making eighteen years the marriageable age for women, also permitting civil as well as religious ceremonies of marriage.

CONTAGIOUS DISEASE LAW INADEQUATE. Dr. J. M. Parker, who was tried in the police court last week for alleged violation of the contagious disease act, was discharged, the Government failing to establish its case. The judge in dismissing the case said that it was with great reluctance that he had to dismiss the charge, but he had to do so because the law was inadequate to meet the case. He sincerely hoped the law would be amended to cover every phase of contagious diseases, and said that when doctors can not agree the laymen ought to take the matter in their own hands.

MEDICAL SOCIETY. At the regular meeting of the Society held on the 19th, Dr. McGuire read a paper entitled, "Freaks as Pertaining to Diseases of the Skin," the subject was accompanied with illustrations. Dr. James Kerr reported a case of "Supra-malleolar Osteotomy for Deformity following Pott's Fracture." Dr. Acker presented a case and specimen of tumor of the heart and lungs. Dr. J. Ford Thompson presented a specimen of myoma of uterus and a tumor removed from the submaxillary space.

WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.—At the 241st meeting of the Society Dr. J. F. Scott read an essay entitled, "Gonorrhea in Women." Dr. J. T. Johnson presented a uterus he had removed per vaginam for cancer.

SCIENTISTS DISAPPROVE THE ANTI-VIVISECTION BILL. The anti vivisection bill (S. 1552) now in Congress was discussed on the 20th inst., at a meeting of the joint commission representing scientific societies. The joint commission is composed of the officers and executive committees of the seven scientific

societies of Washington, i.e., the Anthropological, Biological, Chemical, Entomological, Geological, National Geographic and Philosophical societies, representing a total membership of nearly 2,000. Dr. Charles Dabney, assistant secretary of agriculture, gave a résumé of the anti-vivisection bill, and proposed resolutions, which were unanimously adopted. The resolutions declared "That the joint commission of the scientific societies of Washington, composed of officers of the several scientific societies of the city, most earnestly opposes the legislation proposed by Senate bill 1552, entitled 'A bill for the further prevention of cruelty to animals in the District of Columbia'; that in the opinion of this commission the proposed legislation is unnecessary, and would seriously interfere with the advancement of biologic science in this District; that it would be especially harmful in its restriction of experiments relating to the cause, prevention and cure of the infectious diseases of man and of the lower animals; that the researches made in this department of biologic science have been of immense benefit to the human race; and that, in general, our knowledge of physiology, of toxicology and of pathology, forming the basis of scientific medicine, has been largely obtained by experiments upon living animals, and could have been obtained in no other way; that physicians and others who are engaged in research work having for its object the extension of human knowledge and the prevention and cure of disease are the best judges of the character of the experiments required and of the necessity for using anesthetics, and that in our judgment they may be trusted to conduct such experiments in a humane manner, and to give anesthetics when required to prevent pain. To subject them to penalties and to espionage, as is proposed by the bill under consideration, would, we think, be an unjust and unmerited reflection upon a class of men who are entitled to our highest consideration."

It was decided to send a copy of the resolutions to each member of the committees on the District of Columbia in the House of Representatives and Senate of the United States and to the District Commissioners.

THE PUBLIC SERVICES.

Army Changes. Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from February 15 to 21, 1896.

First Lieut. William W. Quinton, Asst. Surgeon, is relieved from temporary duty at Ft. Logan, Colo., and ordered to Ft. Grant, Ariz., for duty at substation, San Carlos, Ariz., relieving First Lieut. Paul F. Straub, Asst. Surgeon. Lieut. Straub, on being thus relieved, is ordered to Angel Island, Cal., for duty at that post, relieving First Lieut. Charles E. B. Flagg, Asst. Surgeon. Lieut. Flagg, upon being thus relieved, is ordered to Ft. DuChesne, Utah, for duty at that post, relieving Capt. Henry D. Snyder, Asst. Surgeon. Capt. Snyder, upon being thus relieved, is ordered to Ft. Ethan Allen, Vt., for duty at that station.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending February 22, 1896.

Surgeon D. M. Guiteras, detached from the "Montgomery" and granted six months' sick leave.
P. A. Surgeon L. W. Curtis, detached from duty at Indian Head proving ground and ordered to the "Montgomery."
Asst. Surgeon L. Morris, detached from the naval hospital at Philadelphia and ordered to the Indian Head proving ground.
Medical Inspector Dwight Dickinson, ordered as member of the retiring board February 28.

Change of Address.

Barrie, Geo., from 1269 O St. N. W. to 1355 Cochran St. N. W., Washington, D. C.
Brauns, E., from 416 E. North Ave. to 3 Lincoln Ave., Chicago, Ill.
Rowe, S. B., from 2908 Gamble Ave. to 925 Bayard Ave., St. Louis, Mo.
Shms, S. N., from Philadelphia, Pa., to St. Joseph, Ill.

ADDRESS.

ADDRESS ON OBSTETRICS.

Read before the State Medical Society of Pennsylvania at Chambersburg, May 23, 1895.

BY W. B. ULRICH, M.D.

CHESTER, PA.

In taking up the evidences of recent progress in obstetrics, I wish first to call your attention to the growing appreciation in all civilized communities of the services of the skillful accoucheur. Then we remember that when Dr. Wm. Shippen, Jr., began his lectures in Philadelphia, in 1765, a little over a century ago, the practice of midwifery was entirely in the hands of nurses, mostly of the Sairy Gamp style so graphically described by Charles Dickens, and the physician was only called in after some grave emergency had arisen and the life of the patient imperiled. When we recall the fact that it was not until 1808 that the trustees of the University of Pennsylvania created an independent Chair of Obstetrics in the faculty, and made the attendance upon the lectures obligatory upon the students, we begin to realize the great strides that have been made in this, the latest born department, the most vigorous child in the entire medical curriculum. Very much light has been thrown upon this subject by recent advances in bacteriology and in antiseptic surgery. We no longer discuss the question of the contagiousness of puerperal fever; but, when sepsis unfortunately occurs, we proceed at once to determine the source of the infection, eliminate the poison, and check its pernicious activity. Increase of knowledge brings increase of responsibility. The obstetrician of the present day is a man of vastly more information, has a higher appreciation of the importance of his chosen department, and consequently has a keener sense of the grave responsibility resting upon him than those of earlier times. Carelessness, ignorance and neglect can no longer be tolerated in the lying-in room in view of the serious consequences which result and which may, almost in a moment, convert the house of rejoicing into a house of mourning.

I hold strongly to the opinion that labor is a purely physiologic function, and strictly a normal process of the organism. There is no such thing as unnatural labor, and I am entirely opposed to that mental attitude which would divide presentations or deliveries into those which are natural and those which are not natural. Given certain conditions, certain contingencies must arise, but even the most difficult and complicated labor is still a natural one. It is true, however, that the conditions attending the parturient state may be those which we recognize as being the most favorable to the expulsion of the child, or, on the other hand, various obstacles may be encountered which more or less interfere with delivery and produce difficult labor. A logical division, therefore,

would be into, 1, ordinary or uncomplicated labors, and, 2, exceptional or difficult labors.

With regard to the first group, which comprises more than nine-tenths of all the cases, the present teaching of obstetric science is simply to secure cleanliness and to interfere as little as possible. Many a normal case has been converted into a pathologic one by too frequent digital examinations, especially where the examining finger has been the bearer of infection. Many a natural labor has been complicated by lacerations, owing to the desire of the attending obstetrician "to hurry things up" so that he could get off to keep some other engagement not always professional. Many a physiologic parturient process has been rudely checked and converted into a pathologic one by the over-zealous attentions of a physician who seems bent on demonstrating the truth of the old aphorism, "Meddlesome midwifery is bad." In the majority of cases nature is perfectly competent to accomplish the delivery of the mother without assistance.

Just consider for a moment the logical import of the teaching that a woman after confinement is in the same condition, as a case of amputation with a supposed infectious wound, and that blood-poisoning will develop unless vigorous antiseptic measures are taken to protect her from it. If nature had, with inconceivable malignity, laid a trap, from which there was no escape for any parturient woman, unless the antiseptic art of the obstetrician should release her, how could the human race have survived all these dangers, while waiting for the doctrine of antiseptics to be developed and carried into practice? If these precautions and attentions are necessary in every case, how is that savage races with their rude midwifery methods do not perish from the face of the earth? When I practiced medicine in the State of Louisiana, a woman stopped and spent the night at my house who had been captured by the Comanche Indians with her husband and two sons. The husband and sons were killed in her presence. She lived for three or four months with the Indians and, during this time, she was pregnant and miscarried at the sixth month, while in captivity. She told me that the Indian women marched with their husbands until they were taken in labor, and then they were helped to the nearest pool of water. As soon as the child was born it was plunged into the cold water. If it struggled vigorously it was allowed to live, if not it was drowned. The mother also went into the cold water as soon as the after-birth was thrown off. The child was then strapped upon her back and she followed the tribe and resumed her work as if nothing unusual had occurred. The point that I make is not that this is the best treatment for the lying-in patient, but it is that, even with the neglect of everything that we regard as essential, nature does the work and the great majority of mothers actually do survive the perils of childbirth.

I am also strongly opposed to the resort to instru-

mental delivery merely to suit the convenience of the physician. Now, I do not want to be misunderstood. I look upon the forceps as the most humane of instruments, and do not stand aside and hesitate when they are to be used in the interest of the mother or child. Some years ago, by invitation, I went to hear my friend, Dr. Albert H. Smith lecture before the Philadelphia County Medical Society on the use of the forceps, and in the discussion of the paper I expressed my disappointment, and said that "I had come up to learn when not to use the forceps." He thought that the forceps should be used whenever there was the slightest delay to the passage of the child in the second stage of labor, that the patient should not be allowed to suffer. It requires good judgment to recognize when to refrain from using the forceps. There is oftentimes too much haste to resort to their powerful aid; traumatism may be thus produced, and a dangerous chain of consequences be initiated. My conviction is that the obstetrician has no right to consider himself at all, but only his patients, in the process of labor. In other words, I would state the duty of the obstetrician, in attending a case of normal unobstructed labor, is to be summed up in the words "cleanliness" or "asepsis." He should be on the alert, ready to render assistance should occasion arise, but otherwise he should practice a policy of non-interference. I believe the old country doctor, who boasted that he had never used the forceps and stated that plenty of good fresh lard and a good deal more patience were all the instruments he wanted, is far safer than many of the present day who seem to feel called upon to use instruments in nearly all their cases. Even at any time in the most skillful hands, there is always more or less danger to the integrity of the soft parts, and when used to save time for the doctor, or magnify his importance, I consider it a crime.

While insisting upon the usefulness of a warm soap and water bath at the beginning of labor and a preliminary douche to cleanse the birth canal, if the patient does not seem to be cleanly, especially in lying-in hospitals, I am opposed to subsequent repeated douching and especially to irrigation of the uterus after labor except where absolutely indicated to overcome an actual septic condition, due to retained placenta, or other cause. Chemic disinfectants are not required to obtain and maintain a condition of asepsis, and their routine use is to be deprecated in the parturient woman. On the other hand, I would commend the practice of rendering the hands of the obstetrician and all instruments used by him, as aseptic as possible by the abundant use of soap and hot water, followed by a rinsing with solution of bichlorid of mercury (1 to 2000). By the universal adoption of this plan of treatment, puerperal septicemia may be eliminated from among the risks of childbirth. By carrying it out at the Preston Retreat and in private practice, Dr. Joseph Price claims that he has not had a case of this character in nearly ten thousand labors. Moreover, there is an incidental advantage by the adoption of this method, which deserves our serious consideration. It is the abolition of ophthalmia neonatorum. Dr. Price has recently stated that infantile ophthalmia has been banished from his practice by the adoption of asepsis in the conduct of labor, and it has been claimed that three-fourths of the blind asylums could be closed for want of inmates, if this plan of conducting the obstetric procedure were universally followed. I have never kept a record

of my obstetric cases, but in a very active practice of forty-six years they have run into the thousands. I do not remember to have had a dozen cases of sore eyes and not a single infant lost its sight. I conscientiously assert that I never lost a patient in labor, or as the result of labor. I do not say this in a boastful spirit, for I feel that I have been more blessed than skilled, but I say it because it is a fact, and I think my scrupulous regard for cleanliness has had something to do with it.

During the past year, a law has been very carefully framed by a committee of this society and has now passed the legislature, which has for its object the prevention of blindness. It makes it incumbent upon midwives, obstetricians and health officers to see that an infant with sore eyes shall receive prompt attention, in order that its sight may not be lost through neglect. While we thoroughly approve of the humane motive which inspired this legislation and anticipate great benefit from its enforcement, we still think prevention better than cure, and insist upon the prophylactic value of absolute cleanliness in the conduct of labor, as conducive to the best interests of both mother and child.

Just here I want to frown upon the fad of the routine use of anesthetics in labor to save suffering. Who can tell what the effect of these God-given pains, the result of nature's force, may have upon the mental economy of the mother? The use of anesthetics and the hasty removal of the placenta by traction are most fruitful sources of post-partum hemorrhage, and of asphyxiated infants. I do not intend to discuss the medical treatment of the puerperal period; but would simply offer a word of protest against routine. Unless there is good reason to be given, the fluid extract of ergot should remain in the bottle, likewise the castor oil, quinin and the malt liquors. Meddlesome midwifery is bad and so is officious medicine-giving. There is a principle in letting well enough alone and it takes some experience and good judgment to know when to do it. Oliver Wendell Holmes, in speaking of the abuse of physical diagnosis, said that some patients "are done to death with the pedantic foolings of the specialist," and the remark applies with peculiar force to midwifery practice. In connection with this subject as a collateral branch, I may refer with commendation to a recent communication to the Philadelphia County Medical Society by Dr. W. Reynolds Wilson on the treatment of ophthalmia neonatorum by irrigation with distilled water.¹

It is gratifying to note that with an increasing familiarity with the conditions of delayed labor, there have been devised methods which are favorable to the preservation of the life of both the mother and the infant and that the dreadful alternative involving the sacrifice of human life by craniotomy is now rarely presented. In case of eclampsia at term and also in the condition of placenta previa, requiring rapid evacuation of the contents of the uterus, I must speak in terms of high commendation of the method of rapid manual dilatation and delivery devised by Dr. Philander A. Harris, of Paterson, N. J., first described in the *American Journal of Obstetrics* last year.² In a discussion of the subject of "accouchement forcé" before the Philadelphia Obstetrical Society, Dr. Harris recently reported³ his entire experience with his

¹ Medical News, April 13, 1895.

method in placenta previa and eclampsia, and stated that in all cases in which there were no labor pains or partial dilatation of the os uteri before he attempted delivery, he had not lost a single case. This certainly marks a great advance over the older methods of treating these great complications of pregnancy.

Since the introduction of aseptic methods of operating an expedient in cases of contracted pelvis devised over a century ago, by a Frenchman, M. Sigault, symphysiotomy has been revised, and is being largely practiced with increasing amount of success. An able paper on this subject was read at the last meeting of the Society by Dr. Horace Fox, of Philadelphia. Dr. Robert P. Harris, of Philadelphia, the well-known statistician and recorder of the Cæsarean and Porro operations, is now enthusiastically in favor of symphysiotomy, the mortality of which according to the authority in the last seventy-five cases has been less than 10 per cent. In one of the recent cases in the State of Washington a child of fifteen pounds in weight was delivered by this method which only a few years ago might have been sacrificed. Symphysiotomy may be an operation of election or of necessity; the former when the patient is seen during the progress of pregnancy; the latter when the obstetrician is called in to attend the case after labor has been initiated. The simplicity of the procedure as compared with the Cæsarean section, or any mutilating operation, and the brilliant results obtained by it with proper management, certainly warrant its general adoption in appropriate cases. The method of performing the operation is given by Professor Farabœuf as follows:

"The woman is placed in the dorsal position with the thighs abducted and flexed upon the abdomen and held in that position by two assistants. The pubic region is shaved and this, with all the adjacent parts, is washed first with soap and water, then with sulphuric ether and finally with a solution of bichlorid, or of biniodid of mercury (1-2000). The patient is then fully anesthetized, catheterized and a vaginal douche given. The length of the incision varies with the length of the symphysis in different subjects and must be made, vertically, midway between the two spines of the pubis beginning at the level or a little above the superior border of the symphysis and descending to its inferior border, deviating in the neighborhood of the clitoris without touching the superior part of the vulva. Then cut through all the soft tissues down to the cartilage and do not stop to seize any bleeding vessels. Then upon the index acting as a guide, with the scissors divide the fibro-cartilage at the level of the anterior surface and superior border of the symphysis. Then we make two small incisions transversely beginning at the median line close to the superior border of the symphysis in such a way as to cut through the aponeurotic tissues in order to make a passage for the index, which is then introduced along the posterior surface of symphysis. The finger then feels very well the posterior prominence of the fibro-cartilage of the symphysis. Left in this position it serves as a protection to the organs lying posterior to the symphysis. With a straight scapel, begin cutting the cartilage from before backward and from above downward and finish the section by means of a blunt pointed bistoury. At the moment of cutting through the sub-pubic ligament by means of a sound introduced into the bladder, an assistant pulls the urethra out of the way. The incisions,

through the cartilage are kept up as long as the knife continues to creak, for the latter indicates the resisting cartilage and ligaments giving way. The operator feels the structures slowly giving way, and, finally, when all is cut, the iliac bones in a measure separate. The assistants now practice slow and progressive abduction of the thighs. The surfaces of the divided cartilage separate from each other and we are thus enabled to introduce between them one or two fingers, according to the degree of separation. Experience teaches us that no damage to the sacro-iliac articulations can be brought about by a separation of 7 centimeters. The separation can be brought about by the operator himself with the assistance of the *écarteur* designed by Prof. Farabœuf. When that degree of separation which the operator deems sufficient is obtained the assistants must be warned not to move, but to hold the limbs in that position thus attained. A tampon is placed in the wound, and this may be either a sponge, absorbent cotton, or iodoform gauze. The operation being completed, we now proceed to the extraction of the fetus. The extraction of the fetus is done artificially. We apply the forceps according to classical rules, *i.e.*, on the parieto-malar region of the flexed head. We pull and the head easily descends, separating the pubis as it advances, provided the latter separation have not been sufficient. If any great resistance is experienced, we must not exercise too much force, but continue to separate the pubis to the limits allowable. As the head descends transversely in the excavation we must subject it to a rotary movement so that it may pass through the inferior muscular and osseous tracts. Here a most important maneuver, advised by Dr. Varnier, must be resorted to in order to avoid the many injuries to which the anterior vaginal wall is liable in the hands of inexperienced operators. If we examine the vulva and soft parts while the iliacs are separated, we find that they no longer present an orifice, longitudinal from above downward and from before backward, but one which is stretched transversely, with a large transverse axis, and whose superior part now lacks support, since the bones are separated. The head, which has been subjected to the rotary movement above mentioned, now presents its largest diameter longitudinally to the largest diameter of the orifice, which is directed transversely. The head presenting itself in this position, any effort to extract the fetus would undoubtedly produce rupture of the vulva and of all the soft parts, where support is lacking, *i.e.*, where the pubis has been separated. A tear of the anterior vaginal wall is a most inevitable result. In order to obviate this Dr. Varnier advises the following method of procedure which is most simple: When the head has effected its rotary movements the assistants approximate the thighs, thus causing the separated iliacs as well as the transversely stretched vulvar orifice to resume their normal position, and the head as in any normal confinement is delivered without producing any injury to the inferior osseous and muscular straits or vulvar orifice. The operation is now terminated as to its essential parts. The umbilical cord is tied or compressed and divided, after which the new-born child is given to an assistant or nurse. A vaginal injection is now given and artificial delivery of the placenta is performed. The vagina being well packed with iodoform gauze, we next devote our whole attention to the pubic wound. The tampon which was previously placed in the wound is removed and the wound is irrigated with

a 5 per cent. carbolic solution, or biniodid of mercury (1:2000). The assistants approximate the iliacs by continued pressure on the hips, and the operator proceeds to suture the tissues with two or three buried sutures and as many superficial ones to keep the parts in perfect apposition. The wound is then covered with iodoform gauze and antiseptic absorbent cotton. A tight bandage is then placed around the pelvis and this covered over with a second one in the form of a T. A third bandage intended to give support is then applied, and for this plaster of Paris is used. We must apply this in oblique directions so as to leave the pubic region free, and so allow freedom for future dressings. These latter dressings must be renewed very often, at least twice a day, because they are always soiled during micturition. The vaginal dressing may be allowed to remain for two or three days, as it insures the perfect antisepsis of the vagina, and thus we can dispense with the injection which would otherwise be necessary during this period. It is necessary also that the limbs should be immobilized by strapping them together. Of course, under these conditions, it is difficult to give injections, so that it is quite sufficient to wash the vulva after each micturition. About the eighth day the wound has become cicatrized. Often enough you will find that edema of the pubes has caused the sutures to cut through the tissues. These may be taken out at the rate of one or two a day."

Now the merit of this operation is that it saves the child with a minimum risk to the mother. Notwithstanding the operation has sometime to be hurried so as to complete it before the child has been naturally delivered, I look upon it with more favor than the Cæsarean section or craniotomy.

I find that I have dwelt at such length upon the operation just referred to that I have no time to discuss delayed labor due to unusual presentations or positions of the fetal organism. In occipito-posterior position it has lately been advised to manipulate the head before the second stage has begun, so as to convert it into an occipito-anterior position. The change was advocated by Baudelocque, Dewees, Hodge, Meigs and others, Dewees going so far as to say that "a physician was incompetent to practice midwifery in the best manner who could not detect and change the malposition of the head and thus abridge by several hours the misery and pain of his patient." In my own experience I have not always found this an easy thing to do. With present methods of securing asepsis this method of changing vertex posterior into vertex anterior positions should be more commonly practiced, or at least attempted.

In the treatment of many of the mechanical causes of delayed labor due to foreign growths in the uterus or vagina, and in the conditions complicating labor, such as ruptured uterus, hematoma, etc., and some of the sequelæ such as pelvic abscess, pus tubes and uterine sepsis, as much technical knowledge, special training and sound judgment are required as are demanded in any other department of medical science. An encouraging amount of progress toward the satisfactory solution of these many unsettled questions of practice, is shown by the proceedings of our special societies and the pages of our medical journals. The scope of the questions suggested by these topics, goes beyond my present opportunity and I find that I have no time to devote to the consideration of these important problems and the manner in which they are being

solved. I would only make a plea not only for careful diagnosis but also for more individualizing of patients in deciding questions of prognosis and treatment, and not too much zeal for manual and mechanical interference.

FIBROID TUMOR OF THE UTERUS: DIAGNOSIS.

BY FRANKLIN H. MARTIN, M.D.

PROFESSOR OF GYNECOLOGY POST-GRADUATE MEDICAL SCHOOL OF CHICAGO; SURGEON TO WOMAN'S HOSPITAL.

A knowledge of the existence of a fibroid tumor of the uterus may be gained by the diagnostician by first obtaining the symptoms as appreciated by the patient, the subjective symptoms; and further by acquainting himself with the actual physical changes by direct personal examination of the patient, the objective symptoms.

SUBJECTIVE SYMPTOMS.

Pelvic Symptoms.—Among the early local symptoms of fibroid tumors of the uterus may be enumerated an irritable bladder amounting frequently to positive dysuria; rectal pressure; sensation of pelvic fullness; low backache or sacralgia, and frequently pain on cohabitation. These symptoms are all produced by a gradually enlarging uterus, and resemble many of the pelvic disturbances of early pregnancy, from which they must be differentiated. As the tumor enlarges the sensation of fullness extends to the lower abdomen, the pressure on the nerves to the lower extremities causes pain in the line of the nerves on the anterior or posterior aspect of the thigh, or on both. Even edema of the extremities may occur from pressure on the veins extending to them, and the appendages are frequently pressed upon, resulting in severe pain on one or both sides, while as the tumor begins to fill the abdomen symptoms of painful pressure on many or all the important organs of the pelvis will be experienced.

Symptoms due to Functional Disturbances.—The most important symptom under this head is that due to the disturbance of the function of menstruation. In 75 per cent. of all fibroid tumors of the uterus the menstrual flow is increased, on account, 1, of increased area of the endometrium due to interstitial enlargement of the uterus, 2, of increased vascularity of the uterus due to the demands of the hypertrophied tissues, and 3, to the venous blood congestion due to pelvic pressure. In a large majority of cases pain is an accompanying symptom. This dysmenorrhea is caused, either by the abnormal contractile power of the changed uterus, by submucous projections into the uterine cavity, exciting painful contractions of the organ, or by a frequently accompanying endometritis. The development of the tumor influences decidedly the change of the menstrual function. In the early stages of the fibroid the patient will notice but a slight lengthening of the menstruation, but as further development is made the quantity of the flow will be increased. This changed condition, while at first it may attract the attention very slightly, as it gradually increases, will at last convince the patient that something serious is afflicting her. The flow will increase rapidly, not only in length of period, and in quantity at a given time, but finally it will frequently become irregular and occasionally almost continuous. At the

same time pain will often gradually develop, so that with the exhaustion of depletion will come the agony of physical suffering. These pains if caused by endometritis, will be of a dull aching character, accompanied occasionally with slight uterine contractions; if caused by the effort of the uterus to expel submucous masses or polypi, it will be like those accompanying the uterine expulsive pains of a miscarriage or confinement; if caused by a pressure of the inordinately congested hypertrophied uterus upon the tubes and ovaries it will be severe and of an almost continuous character in the ovarian regions.

The function of the bladder suffers from direct pressure of the enlarged uterus, or from a subperitoneal enlargement. Frequent urination will first be noticeable, while the tumor is yet small, and later painful micturition, with severe lasting pain in the bladder, as a direct result of traumatism produced by the encroachments of the uterus. Complete stoppage of the urine and painful distention of the bladder may finally occur from impaction of the increasing tumor.

The function of the rectum is frequently impaired by direct pressure of the tumor upon that organ. Obstinate constipation will be complained of, while the interference of the tumor with the circulation will favor the development of hemorrhoids and their painful symptoms. Temporary impaction of feces in the large and small intestines occur as a direct result of the pressure of a large tumor.

Deformity Produced by Fibroids.—One of the most embarrassing symptoms to many patients, who are afflicted with fibroid tumors, and frequently the first to attract their attention, is the change in the contour of the abdomen, which is enlarging. Upon closer observation and examination of the lower abdomen, they discover the unwieldly mass, the tumor, which, as it gradually increases in size, produces a deformity that no device can conceal, while the patient, in order to maintain an upright position, must throw her shoulders back in a manner to make the tumor appear most embarrassingly conspicuous.

General Constitutional Disturbances.—Reflex nervous disturbances are early symptoms in many of these cases. Nausea, palpitation of the heart, indigestion, gaseous distensions of the bowels, flashes of heat due to vasomotor disturbances, headache, dizziness, occasionally spasmodic cough and all the symptoms accompanying nervous storms, irritable temper, despondency, and lack of control, finally developing into typical hysteria. These symptoms are precipitated ordinarily by irritation caused by the long-continued local disturbances already described, and by loss of blood due to excessive menstruation.

Anemia naturally, in a large number of cases, becomes a conspicuous subjective symptom. The patient will complain of loss of flesh, her skin has become pale, lips pale and blue, muscles loose and flabby. She tires easily, and all exercise induces shortness of breath and heart palpitations. Frequently it is necessary to remain in bed a large part of the time from weakness, which is much more pronounced immediately following the great waste of the menstrual period.

OBJECTIVE SYMPTOMS.

Diagnosis.—Under objective symptoms methods of diagnosis will be considered. Objective symptoms are determined, and their diagnostic value recognized,

by pelvic examination, abdominal palpation and auscultation, and general examination.

Pelvic Examination.—The patient should be placed on her back on an operating chair or table, in the recumbent position, with limbs well flexed upon the abdomen, and feet supported by short stirrups. The clothing should be loose. After the vagina has been well douched with an antiseptic fluid, the examiner should proceed to make a bimanual pelvic examination. The index finger of the left hand is employed to make the preliminary vaginal examination, the right hand being left free for external manipulation. The cervix is first sought and its location often gives one important information. If it is in normal position, well up in the vagina, within an inch and a half of the sacrum, any enlargement of the uterus is liable to be uniform, or any growth is located anteriorly in the body of the organ. If it is low in the pelvis and anterior to its natural location, any enlargement of the uterus is quite likely to exist in the fundus, or the uterus is retroverted. If it is anterior to its normal position and is crowded well up behind the symphysis, the tumor is liable to be located in the posterior wall of the uterus, very low. If it is drawn well up posteriorly, almost if not quite beyond reach, the tumor will usually be found in the anterior uterine wall. The location of the cervix, however, is of small importance when considered alone.

Bimanual Examination.—By combining with the digito-vaginal examination, external palpation with the hand, a knowledge of the general contour of the uterus can be at once definitely obtained. If it is enlarged, that fact is apparent; if there are any irregular projections or developments from any portion of its walls into the abdominal cavity, or into the broad ligaments, they can be recognized; and if it is enlarged so as to produce a prominent tumor a knowledge of its source of development can usually be determined by taking into consideration its relation to the cervix. If the tumor is of a subperitoneal variety, its relation with the cervix and uterine body will indicate its source of development. If the cervix is thin and stretched over a projecting mass, protruding through it from the uterine cavity, the knowledge of a uterine polypus or a submucous tumor is imparted. The sensation of solidity or fluctuation of the growth is usually satisfactorily obtained by this examination. Thus, the size, contour, consistence, direction of development and variety of tumor may all be determined by a simple bimanual pelvic examination.

A bimanual examination, however, is frequently unsatisfactory, until one has resorted to a rectal examination, combined with the abdominal palpation, and made either with or without an anesthetic. This latter enables one to examine the posterior aspect of the uterus much higher than is possible per vaginam, and with less intervening tissue. An anesthetic, when given, permits of a much more prolonged examination, renders the procedure painless, and eliminates the muscular fixation and strain which is inseparable from an examination without it. The abdominal muscles, the sphincters of the rectum and vagina are relaxed, allowing much freer and more complete exploration, when an anesthetic is employed.

Instrumental Examination.—Pelvic examination for fibroids is often not complete without instrumental examination. While a speculum is not often needed as a direct means of diagnosis, in these cases, it is frequently required to aid in determining sec-

ondary changes which may have occurred in the vagina or cervix uteri. It may also be employed to explore the cervix where the vaginal vault has been distorted by a complicated tumor, before using the uterine sound. The uterine sound is occasionally used to measure the uterine canal. It may be employed to locate the canal when palpating the uterus for the purpose of ascertaining in which portion of its mass a tumor is situated. And it will also give valuable information in regard to the location and size of submucous fibroids. When a uterine canal is so distorted that a metal sound does not possess the necessary flexibility to traverse its course, an ordinary male flexible bougie, with a bulbous tip, can frequently be successfully insinuated to its entire depth, and give very valuable aid in diagnosis. The uterine dilator is an important instrument in diagnosing the condition of the interior of the uterus. It enables one to explore the cavity of the uterus with the finger and thereby materially assists in revealing the position and character of submucous fibroids.

Abdominal Palpation.—Abdominal palpation and auscultation can best be accomplished with the patient under the influence of an anesthetic. By palpation the tumor can be outlined; any subperitoneal projections noted; its consistency ascertained; abscess or presence of fluctuation considered; its relations to the surrounding organs recognized and the absence or presence of adhesions learned. In auscultation we have an important means of distinguishing fetal heart sounds in the differential diagnosis between a fibroid tumor and a natural or tubal pregnancy.

General Examination.—In the general examination of a patient who has a fibroid tumor, points of change in outlying organs, which may have been the remote result of the tumor and which may have an important bearing on the form of treatment to be adopted, are to be noted. These changes may be found in the heart, the kidneys, the lungs, the digestive tract, the nervous system and the vascular system; but as similar changes may also occur from any form of wasting disease, as diagnostic signs they are not of great importance, and therefore, their consideration here is out of place.

DIFFERENTIAL DIAGNOSIS.

We are often called upon to differentiate between fibroids and the following conditions, which simulate them to a puzzling degree: Ante- and retro-flexions, subinvolution (metritis), cancer, floating kidney, pregnancy, tubal pregnancy, tubal cysts and ovarian cysts.

Ante- and retro-flexions are differentiated from fibroids by the comparative smallness of the uterus, and the lack of characteristic hardness of the fibroid. The sound clears up the condition. If it is that of a normal uterus with projecting fibroid, the mass will be easily palpated in front or posterior to the sound, while if it is ante- or retro-version the sound will follow the canal to the center of the flexed fundus.

Subinvolution (metritis) is distinguished from a fibroid by its history, by its symptoms and by physical signs. The history of subinvolution is that of recent child bearing or miscarriages with subsequent endometritis, while a fibroid seldom immediately follows pregnancy, and when small is rarely accompanied with endometritis. The symptoms of the two conditions differ in the amount and character of the leucorrhea, being profuse in chronic metritis; in the

amount of hemorrhage at menstruation, being profuse in fibroids, while in subinvolution it may be absent immediately following child birth for several months, and of a more normal character when it does exist. Subinvolution in physical signs differs from a fibroid in being of a softer character, resembling the normal uterus in being of uniform contour and in containing no distinct centers of development. With a condition of subinvolution will almost invariably be found an accompanying lacerated cervix and frequently a lacerated perineum. Finally, uterine curettement, antiseptics and a restoration of a torn cervix, will cause a subinvolved uterus to involute to its natural size, while such will not be the case with a similar treatment for a fibroid.

A cancer (uncomplicated) is usually easy to differentiate from a fibroid. Microscopic examination should be made, if practicable, at the earliest possible date. An uncomplicated carcinoma seldom presents a large tumor. If it is of the cervix, a well-defined ring shows the line of demarkation between it and the healthy tissue. An offensive, watery discharge, characteristic of carcinomatous degeneration, is of diagnostic value. Carcinoma of the body of the uterus gives rise to more pain than a fibroma. It, too, ulcerates early, giving rise to the afore-mentioned offensive discharge. The cancer cachexia will also aid in arriving at a differentiation. A carcinomatous tumor is much more liable to give rise to an ascites than a fibroma.

A floating kidney might, under exceptional circumstances, be mistaken for a subperitoneal fibroid. But its position, and especially the discovery of its place of attachment, would dispel all doubt of its being a fibroid. To obtain this knowledge, however, might require a most careful abdominal and bi-manual manipulation.

Normal pregnancy should be differentiated from fibroid tumors first by bearing in mind the subjective symptoms of the two conditions, and second by physical examination. In pregnancy menstruation almost invariably ceases; in fibroids it is almost invariably increased. The history of pregnancy is definite and uniform, with a given size of tumor, while with fibroids the time of growth varies greatly with tumors of the same size. Morning sickness and breast changes are classic symptoms of pregnancy which rarely occur with fibroids. In the physical examination the pregnant uterus is uniform in its development, giving a soft, semi-fluctuation feel on palpation. Fibroids are frequently irregular in outline, and on palpation appear solid and often present distinct centers of hardness. The cervix is soft and patulous in pregnancy, and the neck of the uterus sometimes thin, forming a decided constriction, while in fibroids the cervix is unyielding and the constriction of the neck is absent. The vagina in pregnancy is blue, a rare occurrence in fibroids. Finally, as the pregnancy progresses ballottement, fetal movements and fetal heart sounds remove all doubt of the condition.

Tubal pregnancy would rarely be mistaken for a fibroid of the uterus. It presents many of the signs of normal pregnancy. There is frequently a slight show at menstruation, the tumor is of a semi-fluctuating character, and lies, as a rule, to the right or left of the uterus; while a subperitoneal fibroid, located in the position usually occupied by a tubal pregnancy, would be hard and unyielding. In tubal pregnancy

the normal uterus may be distinguished by a line of demarkation between it and the tumor.

Ovarian cysts are usually easy to distinguish from fibroids by their fluctuation; by the lateral development when small; by the slight menstruation accompanying them; by the normal size and depth of the uterus and by the absence of the uterine souffle distinguishing a fibroid. As a rule, ovarian cysts are of a rapid growth and give a short history, while fibroids are years in maturing.

INTERSTITIAL KERATITIS.

BY S. E. COOK, M.D.

LATE RESIDENT CLINICAL ASSISTANT, NEW YORK OPHTHALMIC AND AURAL INSTITUTE.

LINCOLN, NEB.

On account of the transparency of the corneal tissues, enabling us to observe accurately and follow up faithfully any changes which take place in its structure, inflammations of the cornea have for the pathologist more than the usual amount of interest. This is especially so in regard to interstitial keratitis, where the changes are so slow as to be easily followed in part, while some of the phenomena are so completely concealed as to make us even more curious in regard to them. The anatomic seat of the affection is not peculiar to it; the clinical course is, however, and interstitial keratitis presents a well-defined and characteristic picture. In the majority of cases it attacks both eyes, though seldom both at the same time, and usually several weeks, or months, or even years, intervene between the attacks. Owing to this feature the opportunity often presents itself of observing the beginning of the attack in the second eye. The progress of the disease may be very satisfactorily observed as it spreads itself throughout the cornea. In the beginning stages two forms are clinically distinguishable, but these later on can not always be differentiated. In one series of cases the process begins near the center of the cornea and spreads outward toward the periphery, which it usually takes several days to reach. The corneal border may remain quite clear for a time and may appear to be perfectly healthy.

A careful observation of the corneal structures from day to day will reveal the following phenomena: A number of small, dim, grayish maculae make their appearance near the center and in the deeper layers of the cornea. These spots are not clear-cut opacities, with well-defined borders, but are rather diffuse and gradually shade off into the surrounding tissue. They slowly increase both in size and in number, and finally become confluent, forming a large central patch, or in some cases a more or less opaque circle or ring-shaped opacity. At the same time, by the appearance of fresh maculae, the infiltrated area extends toward the periphery. By focal illumination it can be seen that these infiltrated patches have their seat in the deep layers of the cornea, while the surface of the membrane is lusterless and dull, because of a very definite stippling from partial loss of its epithelium. In time, generally several days, the infiltrated area reaches the limbus corneae. The entire cornea is now more or less uniformly white, gray, or even yellow (depending upon the depth of the infiltration), with here and there points of more decided shading, presenting the well-known "ground glass" appearance. Vascularization now begins. Here and there along the corneal margin, as if arising from beneath the limbus, tufts of minute vessels make their appearance. They spring

from the deep episcleral network surrounding the cornea and are therefore branches or offshoots of the anterior ciliary arteries. They run parallel to one another in the deep layers of the cornea and on account of being covered by its clouded superficial layers are usually very indistinct. They are hardly to be distinguished as separate trunks with the naked eye, but are readily recognizable by a strong convex glass—say 20 diopters—behind the mirror of the ophthalmoscope. They produce the appearance of congested areas, usually of a dirty red or grayish red hue, which are familiarly known as "salmon-colored patches."

In the second group of cases the affection is first seen at the limbus and spreads inward. At one spot along the corneal margin the tissue becomes lusterless and clouded. On close and careful examination with a magnifying lens the dull area is seen to be deeply situated and to resolve itself into a number of separate parallel cloudy streaks or maculae. At other spots along the corneal margin similar areas of cloudiness soon appear and push their way concentrically toward the pupillary area of the cornea. At the same time the corresponding portions of the limbus become injected and swollen, and the superficial zone of vessels at the corneal margin begins to develop. As the areas of deep infiltration extend laterally, by increase in number, as well as in extent, until the entire cornea is opaque in its peripheral zone, so do the areas of superficial injection extend in a corresponding manner from the original foci. This development of vessels is confined to the marginal loops of the cornea—those little twigs which extend forward from the posterior conjunctival system to turn on themselves and connect with the anterior ciliary arteries. The entire cornea finally becomes encircled with a raised fleshy ring-like mass of closely pressed vessels, which stop short, however, just within the limbus. In extreme cases it may actually overhang the limbus, and is sometimes called "epaulet-like swelling" of the limbus. The deep vessels, however, which come from beneath the limbus do not stop short with the superficial ones, but continue in the track of the opacities—which they seem to be following up—toward the center of the cornea. Like the vessels in the first form, these vessels run parallel to one another, are very fine and close together and produce the same dull grayish-red appearance of the cornea. Frequently the vessels do not quite reach the center of the cornea and the pupillary space retains its bright gray look.

It must not be supposed that the abnormal action in interstitial keratitis is limited to the cornea, although in most cases the marked visible changes are corneal. There is no doubt, however, that the corneal phenomena are generally secondary. Berry refers to the affection as a secondary infiltration, depending on foci of inflammation in the neighboring tissues. In contra-distinction to this, however, Von Hippel¹ contends that in some cases the affection of the cornea may be primary and propagate itself backward to the uveal tract. It is possible that in some cases in which the center of the cornea is the apparent starting point of the disease the peri-corneal tissues are affected later, but these cases are not of the usual type. At any rate the point is still unsettled. The absence of active inflammation, abscess formation or ulceration of the corneal tissue, all favor the view of the affection being a secondary infiltration. It is

probable that the iris is always more or less involved, although it may be difficult to determine with certainty on account of the opaque condition of the cornea. After the cornea has regained its transparency it is quite common to find posterior synechia, even when iritis had not been suspected, and also in cases where atropin had been faithfully employed from the start to guard against such a contingency. The mydriatic penetrates the thickened cornea with difficulty and probably reaches the irritable iris in insufficient quantity to exercise its physiologic effects. The pupil consequently remains small. Accumulations of cells are frequently found on the posterior surface of the cornea. It is probable that they are seldom or never entirely absent, though it may require a very careful examination with focal illumination and a magnifying lens to determine their presence. Of course this is only practicable during the stage of resorption. Intra-ocular tension is frequently found diminished. The anterior chamber is often deeper than usual, due to an increased secretion of aqueous humor. These changes with the deposits on Descemet's membrane show that the uvea proper is almost universally involved, although it may not otherwise be clinically demonstrable. Its participation may be extremely slight, or on the other hand so marked as compared with the process in the cornea, that the inflammation assumes the character of an irido-cyclitis. We have all the intermediate degrees between a well marked irido-cyclitis, with a few slight opacities in the posterior layers of the cornea, and the densest corneal infiltration without demonstrable extension backward. Hypopyon is very rarely observed even in the worst cases of iritis and uveal involvement. After the cornea has again become sufficiently clear we frequently see foci of vanishing choroiditis. These manifest themselves by numerous black spots in the anterior segment of the choroid. This inflammation of the choroid is much commoner than generally supposed, because of the difficulty of making an ophthalmoscopic examination during the progress of the disease. We have to wait, therefore, for the cornea to clear up in the resorptive stages. Sometimes we have the opportunity of watching this process of anterior choroiditis in the other healthy eye before the cornea has suffered. In some cases scleritis occurs as a complication, confined to the peri-corneal and præequatorial zones. It is diffuse, as a rule, and may result in softening and ectasia. In one case which I saw the entire cornea was pushed forward *in toto*, by a stretching of the sclera in the ciliary region. The cornea had regained its transparency almost completely, the anterior chamber was shallow and the eye had become blind from secondary glaucoma. It is probable that in most cases there is a tendency toward involvement of the scleral tissue, indeed, careful observation will often detect a deep peri-corneal injection of a mild type before the cornea shows any opacity. It is usually a difficult task to ascertain if any deep-seated inflammation complicates the corneal trouble. As however, even in the worst uncomplicated cases, the movements of the hand close before the eyes should be visible, the inability of the patient to see such should lead one to suspect it. The visual acuity should correspond to the condition of the cornea. The field of vision also should be of normal extent. Therefore any limitation of it would indicate some deep complication.

Interstitial keratitis may be accompanied by more or less marked symptoms of irritation, as lachryma-

tion, pain, photophobia, redness and rarely swelling. As a rule they correspond to the amount of vascularization. In some cases they are extreme, in others hardly noticeable, and the patient only seeks medical aid on account of the disturbance in vision. In mild cases this may be so slight that no inconvenience is caused until the second eye is attacked. In severe cases, and in the later stages of some cases with a mild beginning, the disturbance in vision may be so pronounced that movements of the hand can only be recognized a few feet, or even inches, distant.

The course of the disease is extremely chronic. As a rule it is protracted for months and even years. The two eyes are seldom attacked simultaneously, but as before mentioned, a long interval usually elapses. Schmidt-Rimpler² even mentions a case observed by him in which one eye had been healthy for more than a year when the other was attacked. It is rare indeed that both eyes are not attacked at some period of the disease. In mild cases the duration may be short and the changes not marked. A few maculæ may make their appearance, remain a short time, and gradually subside again, without any marked inflammatory symptoms. The opacity may remain confined to the marginal zone, or even to the particular section in which it started. These mild cases may clear up so completely that hardly a trace is left of the disease. Still it is rare that, on a thorough examination by oblique illumination and a magnifying lens, no trace of the disease is discovered. Unfortunately, however, all cases do not run this simple benign course. The intensity of the process and amount of infiltration may be such that the corneal tissue becomes softened, and, yielding to the intra-ocular pressure, becomes ectatic and permanently opaque. As already stated, the surrounding sclera may also suffer in this way. Organization and shrinking of the exudate, with consequent flattening of the corneal surface and dense opacity of its tissue is also to be dreaded in these severe cases. Fortunately such deplorable cases are rare. Between these two extremes we have all grades of intensity. While the physician may find his resources taxed to the utmost to conserve the flagging courage of his patient, on account of the long duration of the disease, he can on the whole give a good prognosis so far as the ultimate recovery of vision is concerned. While a certain amount of vascularization is necessary for the resorption of the exudate, still, when extreme, the vascularization itself is to be dreaded on account of its failure to disappear completely. It is worthy of note that keratitis interstitialis never results in destruction of tissue, so that neither corneal abscess nor ulceration is to be feared.

The pathology of the disease is still somewhat unsettled. The opportunity for making a post-mortem examination has occurred in but a few cases, and in these the disease was in its advanced stages. We are still in doubt, therefore, in regard to the changes at the very beginning of the disease. Von Hippel¹ (speaking with reference to the eye alone) states that parenchymatous keratitis may be primary, *i. e.*, have its origin or point of distribution in the cornea or sclera directly adjoining, from which it is propagated to the uveal tract, or it may be secondary, *i. e.*, first appear in the ciliary body or anterior choroid or iris, from which it extends forward to the cornea. The exten-

sion occurs by way of the ciliary vascular system. The microorganisms are passed through these small vessels, the lumens of which they may partially block, or the vessel walls themselves become affected, and the resulting impeded circulation is followed by failure of nutrition of the corneal tissues. Leucocytes in great numbers make their way through the vessel walls and the corneal tissue becomes infiltrated and loses its transparency. He cites Wagenmann's experiment in support of his views. The latter cut through the two long ciliary and in part the short ciliary arteries. Following this a grayish opacity developed at the corneal margin and overspread the corneal surface. A dense vascularization soon appeared along the border of the cornea and gradually spread inward. This in turn was followed by a gradual return of more or less complete transparency in the corneal tissue. These three stages of infiltration, vascularization and resorption, correspond with the phenomena observed in the actual disease in man. According to this the affection has its seat primarily in the coats of the blood vessels, the corneal trouble being a direct result.

In an autopsy made by Krüchow³ there was vascularization of the deep corneal structures, the vessels had adventitial membranes and contained extremely large numbers of white corpuscles. Mayer⁴ examined a case in which the cornea was much thickened. The deep layers were infiltrated with large round and polygonal cells, which in places were collected in nodules. There was congestion of the deep tissues with perivascular cell aggregations. The epithelium of Descemet's membrane was thickened and covered by masses of cells. Nodular masses also appeared in the iris. The anterior portion of the sclera was thickened, vascular and infiltrated. Choroid normal. The cell accumulations resembled tubercles but no giant cells were visible. Fuchs⁵ saw a case where the continuation of the infiltration into the deep layers of the cornea extended into the ligamentum pectinatum, iris and ciliary body. He found these parts filled with small-celled nodules which much resembled tubercles, but no tubercle bacilli or microorganisms were found. There is a unanimity of opinion with regard to vascularization and cell infiltration, but the initial changes remain unknown.

The etiology of interstitial keratitis is as a rule not obscure. The underlying cause in the majority of cases is syphilis of the hereditary type. Noyes contends that some cases also owe their origin to acquired syphilis. He quotes Horner⁶ in support of his views. Many cases are undoubtedly scrofulous, a few malarial, and probably rheumatism and gout furnish a small quota. Interstitial keratitis belongs to the later manifestations of hereditary syphilis. Hence it often appears as late as the age of puberty and but rarely in infancy. The vast majority of cases occur between the sixth and the twentieth years. To Hutchinson is due the credit of delineating the facial characteristics of hereditary syphilis. What were formerly thought to be evidences of a scrofulous taint, we now know to belong to syphilis. Patients with hereditary syphilis will almost always present some or all of the following peculiarities: The forehead is prominent, with overhanging frontal eminences. The nose on the contrary is flat, with a sunken bridge, producing, on account

of a more or less degree of epicanthus, an apparent increase of distance between the eyes. The upper jaws are ill developed and the teeth will require careful inspection. The upper central incisors are ill developed. They may be stunted as a whole and are abnormally shaped. The cutting edge is short and shows a semilunar indentation. Fine linear cicatrices exist at the angles of the mouth. Old eschars may disfigure the hard and soft palates. Numerous, small, hard, painless, glandular enlargements can be made out in the cervical regions. Nodular, hard, painless swellings occur on the long bones, especially those of the leg. These patients may be otherwise in an apparently robust condition.

As might be supposed from a consideration of the causes, treatment is both local and general. The constitutional dyscrasia must be combatted, although it must be admitted that in constitutional syphilis the results of medication are not encouraging. Mercurial treatment is much less effectual than in the acquired form, and its use should be restricted to the severe cases. It may be given by inunction, using the oleate of mercury 20 per cent. or the usual blue ointment. In children the internal administration of corrosive sublimate (1 to 4,000, a teaspoonful three times a day) is useful. The condition of the gums should be carefully observed. In the milder cases remedies containing iodine appear to be more useful. Syrup of the iodid of iron, cod-liver oil with iron. Blancard's pills of iodid of iron, are all useful. Small doses of calomel 1-10 gr. three times a day have also proved valuable. In weak and cachectic individuals general tonics may be required, as quinine, iron, nuxvomica, etc. Errors of digestion must be corrected. The patient should have an abundance of good, plain food, and should be encouraged to live as much as possible in the fresh air. In the local treatment we endeavor to combat the uveal complications, and later on to encourage the rapid and complete clearing up of the corneal opacities. The moderate use of atropin is always indicated in the early stages; a $\frac{1}{2}$ to 1 per cent. solution may be instilled once to four or five times daily. Formentations with hot water or chamomile infusion often ameliorate the symptoms of irritation. They may be employed for twenty or thirty minutes at a time, several times during the day, until the acute symptoms are over. Later the irritant remedies may be tried cautiously, but *no astringent or irritating remedy should be used while any signs of irritation exist*. Calomel, Pagenstecher's ointment, laudanum, are all good. The yellow ointment may be rubbed in well once daily. These tend to promote absorption if properly and timely used. To the same end Schweigger⁷ recommends the employment of massage of the cornea. Of course at all times the eye should be properly protected from strong light by the use of colored glasses. In severe cases, indeed, the patient should be confined to his bed in a darkened room. Treatment may be demanded for months or even years, especially the use of means to clear up the cornea.

The Bicycle.—The bicycle is still the topic of discussion in many a medical meeting, and a note of warning is constantly sounded against the wheel and its use by persons with any heart trouble. Physicians abroad are almost all devoted to the wheel as a health-giving pastime, but they all assert that rowing is superior to it in every way, one reason being the lack of dust which bicyclers inhale into their lungs.

A WORD ON THE MODERN USE OF THE TERMS INFECTION AND CONTAGION.

Read at the Second Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 25-27, 1895.

BY R. HARVEY REED, M.D.

CHIEF SURGEON C. & A. H., CONSULTING SURGEON, R. & O., AND SURGEON T. O. & C. RAILWAYS.
COLUMBUS, O.

With the advance of the germ theory and its practical application to disease, no small amount of confusion has arisen in our text-books in the use of the word infection.

Dunglison's dictionary, published in 1860, defines the word infection as synonymous with contagion and defines contagion as being the transmission of a disease from one person to another by direct or indirect contact. It also states that the term has been applied by some to the action of miasmata arising from dead animal or vegetable matter, bogs, fens, etc. It says that contagious diseases are produced either by a virus capable of causing them by inoculation, as smallpox, cowpox, hydrophobia or syphilis, or by miasmata proceeding from a sick individual, as in plague, typhus gravior, measles, scarlatina, scrofula, phthisis pulmonalis, or cancer.

By these definitions, you will readily see that the same term is applied to widely different conditions and we are almost justified in saying diametrically different causes.

Thomas, in the edition of his dictionary for 1886, defines infection as being "the communication of a disease by personal contact with the sick or by means of effluvia (whatever that may be) arising from the bodies of the sick; contagion; the transmission of disease from one individual to another of the same species, or from one animal to another of a different class." He concludes his definition by saying the term is sometimes used as synonymous with contagion or agent by which a communicable disease is conveyed.

In the same dictionary he defines contagion as "the communication of a disease by contact or by inhaling the effluvia from one already effected—often used as synonymous with infection." Here, again, we have diametrically different conditions defined as synonymous terms.

Keating, in his edition of 1892, says that infection is the contamination with a poison or virus which has the power of invading and multiplying in living tissues. Communication of disease; contagion; atmospheric contamination. He also defines contagion as being the process by which specific diseases are communicated from person to person. Specific disease may be communicated by contact or by near proximity of the sick to the well, when the process is termed direct contagion. He concludes by saying that if communicated indirectly, by means of clothing, food, etc., infection is the more correct term.

In the 1893 edition of Dunglison's dictionary, we find infection defined as material essential to, and concerned in, the propagation and spread of communicable diseases. The process by which disease is communicated to an individual by diseased germs from the external atmosphere. In the same edition the definition of contagion varies little from that given in the edition published more than a third of a century ago.

Prof. Pepper, in his work on diseases of children published in 1874, defines scarlet fever as being an

epidemic and contagious eruptive fever; and yet we all know that scarlet fever will be communicated from one person to another without the necessity of direct contagion or personal contact. In the same work he states that syphilis may be contracted by direct contagion. Here we have the same definition given in two diseases. The one, syphilis, we know is never contracted except by direct contact, and the other is a disease which is seldom contracted by direct contact, but the germ of which is carried in the air, and if carried in the clothing must be inoculated and thereby the disease introduced into the circulation.

Roberts, in his Practice, published in 1874, defines measles as a distinctly infectious disease; which, according to the definition given to infection by our dictionaries, would mean that it is absolutely necessary to have a healthy person come in direct contact with another afflicted with measles in order to contract the disease, and I am sure there is not a practitioner here this afternoon who will admit that that is necessary. Coming down to our more modern authors, Whittaker, of Cincinnati, defines chicken-pox, in the American Text-Book of Theory and Practice of Medicine, published in 1893, as an acute infection of children. Now, what are we to understand by this? If infection means contagion, and contagion means contact, are we to understand that chicken-pox is transmitted from one person to another only by actual contact? If the definition is intended to mean this, certainly clinical experience proves the contrary, and it can be readily demonstrated that actual contact is not necessary to convey chicken-pox from one person to another. In the same volume, the same author defines smallpox as being a highly contagious disease; and yet, we know that smallpox will be conveyed from one person to another in exactly the same manner as chicken-pox is conveyed from one child to another; yet in the one instance it is called infection and in the other instance contagion. In the same volume, Thompson defines syphilis as a chronic infectious disease; but who is there to-day who will not admit that acute syphilis is only contracted by direct contact? Again, Bartholow, in his Practice, published in 1880, defines hydrophobia as a specific disease due to the inoculation of a poison. If this be true, why should not the same definition be applied to syphilis, when we all know that it is produced by the inoculation of a specific poison?

We might multiply these quotations indefinitely. Our text-books and dictionaries are filled with contradictory definitions of the same conditions, and is it any wonder our students come to us to define what we mean when we refer to infection, and what somebody else means when he speaks of contagion? By these few quotations from accepted authors it is evident that the same terms are used in medicine for entirely different conditions, and applied to diseases which are contracted under, we might say, almost diametrically different circumstances. Owing to this Babylonian confusion of terms, sanitarians in making laws to cover the sanitary condition of States and municipalities, have included both infection and contagion without endeavoring to define what is meant by either, so that the transgressor can not escape on a technical definition of terms. It seems to me, however, that the day has come when a more distinct and definite nomenclature should be applied, and terms should be used which have a definite meaning and which indicate certain definite conditions. Especially

is this true in surgery, where accuracy of language is so essential in conveying a proper idea of the meaning intended by the writer.

The generally accepted term "infection," as applied in surgery, means the introduction into the human economy of some microorganism by inoculation or direct contact. Clinical experience, as well as experimental research, have long since taught us that the infection of a wound by pus microbes means the development in that wound of pus; and if that means anything it means that a specific microbe has been introduced into the wound, and there has found a suitable culture medium for multiplication. We do not as surgeons expect a patient to become infected with pus microbes by reason of the presence of another patient in a distant part of the ward suffering from pyemia, so long as proper care is taken to avoid the conveying, by actual contact, of these microbes. But does that hold good in cases of measles, small-pox, scarlet fever or whooping cough? Certainly not. The presence of a case of any of these in a ward, without actual contact, is liable to produce an epidemic, not from direct contact but from what our old authors called "infection of the air," which is an entirely different method of carrying these diseases from that by which pus microbes are conveyed from one person to another, but which is called infection.

Having briefly reviewed the confusion in the use of the words infection and contagion in medical literature, let us turn for a moment to surgical literature and observe the conditions under which these terms are used in it.

Senn, in his "Principles of Surgery," in speaking of tetanus says that the infectious nature of the disease was well known and established before the discovery of the bacillus tetani. In speaking of the etiology of this disease, he says further that the bacteriology of tetanus is the essential cause of the disease; the remaining causes are accidents, the condition which results in the formation of an infection atrium. In speaking of this infection atrium he says that it is a well-known clinical fact that punctured, lacerated and gun-shot wounds of the hands and feet are most liable to be followed by tetanus. Again, the same author, in the same work, in speaking of pyemia, says that it is a general disease caused by the entrance into the circulation of pus or some of its component parts. In referring to the bacteriologic experiments of Klebs, he says that in his experimental research during the Franco-Prussian war he found this microbe invariably present, notably at the primary seat of infection. In speaking of the etiology of this disease, he says that the location and anatomic structure of the tissue in which the primary infection has taken place exert an important influence in the production of the disease. From these and many other statements by the same author, it is clearly shown that the word infection is used to indicate the introduction into the economy through some form of wound, or some form of bacterial or chemic poisoning, as the case may be. If this be true, then how are we going to harmonize the use of the same word to imply the carrying of a disease in the air and its introduction into the human economy, without a wound of some kind, as is the well-known fact in measles, scarlet fever and diseases of that class?

In "Tilman's Principles of Surgery and Surgical Pathology," by Rogers. Published in 1894, we find the author speaking of the existence of infectious dis-

eases of wounds, and he says that these infectious wound diseases are all caused by bacteria, and gives as examples anthrax, hydrophobia, glanders, etc., which are diseases communicated from animals to man. Actinomycosis, tuberculosis and syphilis, he says, are also due to infection by microorganisms. He further states that bacilli are capable of gaining access to the tissues or fluids through any wound, even the smallest interruption in the continuity of the skin or mucous membrane.

Warren, somewhat in contradistinction to other modern authors, refers to contagion and uses it as identical with infection. In referring to erysipelas, he says it is one of the most frequent of traumatic infective diseases, and further on states that the most frequent point of entrance of the virus is through a wound. In speaking of erysipelas, he says that the occurrence of several cases of the disease in a certain locality, or in a hospital ward, is not necessarily evidence of its contagiousness, for such a concurrence of events may be due to a common cause from which each case has taken its origin. Again, he says: "There are, however, undoubtedly cases which are contagious in the highest degree." The same author in the same work, in speaking of hydrophobia, asserts that it is a disease caused by inoculation, and speaks also of the propagation of syphilis by inoculation. Tetanus, he says is an infectious disease, and yet, it has been clearly demonstrated that tetanus can be produced by inoculation just as well as hydrophobia.

In the "American Text-book of Surgery," published in 1892, the author divides this subject into three principal divisions, and speaks of mixed infection, which, he says, includes all the ordinary septic wounds and likewise those special wounds which are, at times, accompanied with marked tendency to spread inflammation and gangrene; second, the chemic poisons, the result of bites of insects and reptiles; third, microbial infection, such as rabies, glanders, etc.

From these few quotations it will be observed that authors differ very much as to the use of these terms and their application to certain conditions. It is the varied use of these terms and the ambiguous meaning attached to them, that are daily causing confusion among students of both medicine and surgery. It seems to me there should be a revision of our nomenclature and that proper terms should be employed to convey definite meaning. For example, some authors refer to primary infection as being the primary point at which some microbe has entered the economy, and secondary infection as meaning the second atrium occurring in the same person, instead of using multiple infection to show that there are multiple atria of the same germs. For example, in pyemia we have the absorption of pus from a primary point of infection, and we have a dozen or more atria of pus microbes forming as many different abscesses throughout the economy. This is strictly multiple infection and not primary, secondary or tertiary, which is an entirely different thing. Primary infection occurs where there is an introduction of a certain microbe, such as pus, and secondary infection occurs where there is the addition of another microorganism, for example tubercular bacilli, producing mixed infection; yet we find authors using these terms synonymously, and thus confusing students as to the real meaning to be conveyed.

The complicated nomenclature in reference to infection, contagion and inoculation has long since

impressed the author with the importance of having a clear and more specific use of the terms than we have at present. Since I commenced to prepare this paper, and after giving the matter more systematized thought, I am astonished at the irregular use of the same terms in our various text-books. While I feel that I have given the matter but incomplete investigation, yet I am fully convinced that it is high time something should be done to bring order out of chaos. At present we do not feel justified in recommending to the medical profession what particular terms should be used in this connection, but we would recommend that a nomenclature be adopted and terms used that will be definite and which will enable a writer to state clearly what he wishes to convey and will enable the reader to understand without question what is meant.

In closing this paper I would suggest that the Academy appoint a committee of three to consider this question and that a request be sent to the proper officers of the AMERICAN MEDICAL ASSOCIATION and the American Surgical Association to appoint a committee of three from each of their bodies with instructions to form a joint committee from the three associations whose duty it shall be to consider this question and recommend a nomenclature that will be more exact and modern.

It was moved by DR. REED and seconded by DR. L. E. LEMEN, Division Surgeon U. P. R'y, Denver, Colo., that those present who are not Fellows of the Academy be invited to participate in the discussions of the papers. Carried.

DISCUSSION.

DR. H. J. MAYNARD, of Wyoming—I think there is no discussion possible in this case, because I agree with the Doctor that there is great confusion that ought not to be allowed to exist. There has been for years a mixing of terms. You write one word and you are understood, perhaps, to mean another; you write the other and you are understood to mean the first. I think attention should be called to the matter by the different medical societies of the country, so that order may be brought out of chaos in the literature of the profession for the years to come. The suggestion is a good one and well taken, and I do not see how we can discuss it; we certainly can not quarrel with it, and can not object to it.

DR. L. E. LEMEN, of Denver—I am a great deal like my friend from Wyoming: I simply rise to compliment and agree with Dr. Reed in his paper and second his suggestion for a committee of three to be appointed. I know whenever I use one term and mail my communication I am very sorry I did use the other term.

DR. WM. TUOMSON, of Philadelphia—The literal meaning of the word contagion is "to come in contact," and I think if we would adhere more strictly to the literal meaning of those two words, not that I can give you a literal explanation of the meaning now, though I have looked it up several times, it would be of great assistance to us. If a disease we have contracted by coming into actual contact with the wound, like syphilis, would be classed as contagious, and the other as infectious, I think it would help us out materially. The literal meaning of the word contagions is, "coming in contact," and I think everybody will understand, if you come in actual contact with the sore, as you do in syphilis, it would be a contagious disease.

DR. C. B. KIBLER, of Corry, Pa.—It seems to me as if the suggestion offered by the author of the paper is a very wise one and should be considered; that is, that a committee of three be appointed to confer with the other societies on this question. I therefore make such a motion.

DR. E. GRISWOLD, of Sharon, Pa.—The paper seems to deal with facts and the statements the doctor makes are, I consider,

facts, and there ought to be a differentiation between the meaning of infection and contagion. Now, I have differentiated in my own mind, but I have never seen it done in the literature of the profession, or in text-books; and I believe it is important that the word "infection" and the word "contagion" should be defined strictly as can be done by the suggestions made by Dr. Reed. I think it would be a very fine thing, and no doubt be a great benefit to students. I presume Dr. Reed is finding trouble from that source. Students get confused and naturally enough do not know what distinction to make between infection and contagion. I think we had better carry out Dr. Reed's suggestion, which I think is a very good one.

The motion made by Dr. Kibler was seconded by Dr. Maynard, that in conformity with the suggestion made by the author of the paper, a committee of three be appointed to confer with the American Surgical Association and the AMERICAN MEDICAL ASSOCIATION, to confer with like committees from those bodies to take up the subject of the matter suggested in the paper.

DR. REED—I would suggest an amendment to that, that in addition to having a committee appointed here the Secretary be instructed to request those bodies to appoint similar committees to confer with this committee relative to this matter, setting forth the reason for such a committee.

DR. KIBLER—In order to make this thing quite clear, I would like to amend that motion a little, that Dr. Reed, our President and the Secretary be that committee if Dr. Maynard will agree.

DR. MAYNARD—I accept.

The resolution was then reduced to writing as follows:

Inasmuch as there is much confusion as to the proper use of the terms infection and contagion, be it

Resolved, that a committee consisting of Dr. Reed, the President and Secretary of this Academy, be appointed to confer with a like committee from the American Surgical Association and the AMERICAN MEDICAL ASSOCIATION, with the idea of coining a new word that will meet with the approval of the profession.

DR. WM. T. DALBY, of Salt Lake City, Utah—The question of infection and contagion is a question that was brought up and discussed in its entirety by Dr. Hammond, of New York, some ten years ago, and seems to be a very difficult one to handle. Some diseases seem to have both the condition of infection and contagion. After a lengthy essay on this topic he came to the conclusion which we are at the present time, that is a condition of confusion. The question as I understand the resolution is, that a committee be appointed consisting of three Fellows, to confer with like committees of the AMERICAN MEDICAL ASSOCIATION and the American Surgical Society that would represent the three associations. I believe it would be almost impossible to get these nine men together. I think it would be a better idea if this Association, the Academy of Railway Surgeons, would themselves make some effort to define, if there can be a definition at all, between these two terms. If we expect to have a conference with a committee of these other two associations, I am afraid when we meet again a year hence we will be in the same condition as we are now.

DR. REED—Before submitting this proposition, in the paper, I have taken the pains to consult with quite a number of the prominent members of the profession throughout the country relative to this matter, and I have been unable to find any one member who felt that he was able to offer a substitute for the terms used that would be satisfactory from a surgical standpoint; at the same time, every member of the medical profession that I have consulted agreed that the terms were exceedingly confusing. Now if a term is decided upon, if some particular name is suggested, it would be well, it seems to me, to have the indorsement, not only of the American Academy of Railway Surgeons, which you all know is a child, so to speak,

in the arena of American medical and surgical associations, but also the indorsement of the American Surgical Association and the AMERICAN MEDICAL ASSOCIATION. I agree with the gentleman who spoke last, that it would probably be somewhat difficult to get a committee together on the subject, but it is highly important that we should get them together. If we adopt a term, with a membership of one hundred, and start out to use this term, we may find some difficulty in getting this term adopted and we will still remain in confusion. My idea is to have it adopted by the leading associations and especially the AMERICAN MEDICAL ASSOCIATION, that this term may go out and be used by these members, and very soon the terms that are now in use will become obsolete, practically, and the new term as adopted will be taken up. The questions that we are considering now more particularly are those from a surgical standpoint and it is certainly exceedingly confusing to use these old terms. Ten years ago the matter from a medical standpoint was scarcely considered, and it is only since the question of aseptic and antiseptic surgery has become prominent that the term infection has come into use. Unfortunately, it seems to me, we have accustomed ourselves to the habit of saying that a wound is infected, when in fact we mean that something has come in contact with that wound and is introduced into it either a specific poison or a microbe of some character. For us to say that a wound is contagious would sound quite bad, hence we have as a consequence dropped on the word infection, and we say that a wound has become infected when we do not mean to use the word as interpreted by our dictionary. We have used the word abstractly, and for that reason I think it necessary as has been suggested by prominent men, to coin a new word. It has been suggested that we get some parties on this committee from one of the associations who are Latin and Greek scholars; they might be able to coin a suitable word that will express our views on this point more accurately. I concede that while there is a great deal of confusion in this matter there is going to be no small amount of trouble to get a word that will be convenient and will mean just what we want it to mean when we desire to describe the introduction of foreign germs into wounds in surgical practice.

DR. A. D. BEVAN, of Chicago—I am opposed to the resolution. I do not believe that it comes within our field of action. Work of this kind, if it is done by medical men at all, should be done by pathological and bacteriological societies, societies which have a wider scope of action than the Academy of Railway Surgeons. We might as well devote all our time to taking up the many points in contest in the nomenclature of any other line of medical work, and I do not believe that it is wise for us to take up a subject of this kind; I do not think that it would be any great credit to this Association to attempt work in this line. I should like to see the resolution voted down. Work of this kind certainly belongs to lexicographers and biologists and not to railway surgeons, and I believe we should limit our work here to railway surgeons.

DR. REED—I fully appreciate the force of Dr. Bevan's argument, yet at the same time I do not think that the Doctor probably comprehends the difficulty in the suggestion that he makes. Take our pathologists and very few of them are in active surgical practice, with now and then an exception. We who are using the term every day feel the necessity of having something that will give us a definite idea of what a writer is saying when he uses a certain word. I do not think it is right for us to continue to use the word infection when it does not mean what we intend it should. It is not scientific, it is not scholarly, and yet if we wait for the pathologists to come to the front, who care little perhaps as to the use of the word, because they are not using the word in the sense surgeons are, I think we will wait till the snows of Iceland cover Chicago. I think it would be perfectly right, when it comes to the appointment of a committee from the AMERICAN MEDICAL ASSOCIATION, that they

should appoint pathologists on their committee, and it is perfectly in harmony with the resolution that the pathologists should take a hand in solving the question.

DR. MEYERS, of Meyersdale, Pa., spoke in favor of the resolution, which was then read and adopted.

PREVENTION OF TUBERCULOSIS BY FEEDING.

Read by Title in the Section on State Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY EPHRAIM CUTTER, M.D. HARV. 1856, UNIV. PA. 1857.
NEW YORK.

Introduction.—Tuberculosis is clearly the disease whose chief anatomic lesions are tubercles, *i. e.*, little tubers ("small potatoes" indeed) whose dire results are very great. They are minute, ovoid, obovoid or globular bodies, the products of biologic tissue invaded and preyed upon by a parasitic fungus whose infant state is generally deemed to be a bacillus and the mature form to be the mycoderma aceti, which generates acetic acid or vinegar. In other words, the action of the acetic acid of the vinegar plant itself and of the vitality of the invaded tissues result in hard little tubers (tubercles) as is well known. Like, but *large* tubers, are seen in plant biology; for example, the tumors on pear trees invaded by a fungous parasite, whose bacteria, mycelia and fruit (sporangia) penetrate the profoundest depths of the dense woody tissue, cambium and bark, as some twenty years ago I demonstrated by direct solar projections to members of the Massachusetts Horticultural Society at Boston.

In general terms, *tuberculosis* includes: 1, consumption of the lungs, oftenest recognized and is meant when the word "consumption" is used; 2, consumption of the bowels is, in my opinion, the most frequent form and most unrecognized. Foster's dictionary disposes of it in two words, *i. e.*, "tuberculosis intestinalis;" 3, tuberculosis of the joints; 4, visceral tuberculosis. While it is not intended to quarrel with nomenclature here, the writer thinks that the following definition of tuberculosis is most expressive, to-wit: "Partial paralysis and interstitial death."

By feeding is meant the prehension of outside substances that enter the body and become normal parts and parcels of that body, or confer the force needed to sustain life, thus including air as food. This very old idea needs to be revived, as so many now believe that tuberculosis is propagated by inhalation in air unpurified by sunlight and damp with abnormal moisture, in which foreign bodies more easily float in their aerial flight.

Feeding causes Tuberculosis.—One thousand cases of evidence are enough. See "Relation of Alimentation and Disease," by J. H. Salisbury, M.D., 1888. J. H. Vail & Co., New York. Ten hundred and twenty-six healthy swine were fed on sour whisky distillery slop until all were ill; 250 died and 104 autopsies were done in which were found tubercle bacilli. *Per contra*, 600 healthy swine were at the same period of time kept in pens next adjoining the above 1,026 swine, and fed on good sweet maize. None contracted tuberculosis, as they ought to have done according to late dicta adduced in support of the isolation of clinical tuberculosis. The evidence shows that 600 healthy swine penned next to 1,000 tuberculous swine, fed on proper food and breathing air laden with tubercular bacilli from a regiment of tuberculous hogs, *did*

not take tuberculosis. Apply this to man, and you have the proposition that *if you feed healthy people on proper food they will not contract tuberculosis in their vitiated air food.* More of this later, as we wish now to insist that tuberculosis prevails in those who feed on food that ferments in the alimentary canal with the acetic acid fermentation, or are fed on food that contains vinegar in excess before eating. When the mycoderma aceti is confined to the alimentary canal, as it is in very many cases of tuberculosis, consumption of the bowels occurs and constitutes a large majority of the cases of chronic diarrhea. Innate or other strengths of the intestinal epithelia constitute such a barrier that the vinegar yeast does not get into the blood. But when the villous epithelia are paralyzed by the CO₂ gas or made drunk by the alcohol formed in the alimentary canal (unless special means are used to prevent, alcoholic always runs into vinegar fermentation) then the said epithelia lose their power of resistance (much as an intoxicated person does) and suffer the mycoderma aceti to traverse them and enter the blood, where it is easily detected by the microscope, any time within a year before lung necrosis ensues sufficient to be positively recognized by the usual signs furnished by auscultation and percussion. And this microscopic inspection becomes a *sign* of the *pre-tubercular* state. (See essay submitted to the AMERICAN MEDICAL ASSOCIATION, "On a New Physical Sign of the Pre-tubercular State," 1877.)

Why the lung apices are the favorite site of tubercles is well explained by the facts:

That the lung capillaries are very sensitive to, and contract from, the application of cold.

That when in "catching cold" these capillaries contract, catch and detain collections of mycoderma aceti which otherwise would harmlessly pass through the capillaries.

That these form emboli which obstruct the circulation.

That the lung apices being near the outside air are most accessible to cold.

That because of their position in a comparatively inelastic part of the thorax, the apices are not very expansible, save by forced respiration, and thus are an easier prey to tuberculosis than the other parts of the lungs.

And that the troubles caused by the plant and animal tissue in this embolism, retard circulation and produce tubercles somewhat as in the pear blight aforesaid.

To me, the above is evidence ample to prove that improper feeding produces tuberculosis.

In his study of "Evidence," Ram says that "Fact is eternal." A finger put into the fire burns, as a rule. The burned finger is a fact. It makes no difference as to the witness who testifies that "fire burns"—whether an angel from heaven or devil from hell—whether a liar or truthful person—whether a virtuous or unvirtuous man—bond or free—yeoman or nobleman. The fact is eternal that "fire burns." Let doubters try it and see. So I affirm, if the facts as to the 1,000 swine are disbelieved, the doubters must upset the evidence by repeating these experiments. *This has not been done.*

I testify that I have yet to see a case of human consumption where its cause could not be traced to improper feeding more than anything else. The fact is, that society ethics exalt to highest plane, foods which, if not digested, ferment at once with alcohol

and vinegar plants. More than 25 per cent. of the deaths of civilized man are from tuberculosis—the same proportion as in the hogs aforesaid.

Proper Feeding Cures Tuberculosis.—Or, rather, feed properly and, other things being equal, nature cures tuberculosis. To prove this, it is my privilege to refer to the Transactions of the AMERICAN MEDICAL ASSOCIATION, 1880, in which I reported twenty-five out of seventy cases of consumption, cured by stopping causes (improper food): oiling the machine with medicines and by hygiene—nature healing, as she usually does, no matter what you call the means of cure, even in cures by humbug! Nature is the healer, if she has a fair chance, regardless of diagnosis or conventional medical nomenclature. As with the gospel so with medicine: "I," Paul, "have planted, Apollos watered, but God gave the increase." "Nature" means something born. God is the father of nature. Nature, then, is but another term for God's power. Indeed, physicians are but as husbandmen planting and watering, while the cure is nature's.

This item of cure is introduced to complete the full grasp and circuit of the subject. The synthesis and restoration of tuberculosis makes, we think, a ring completely environing the subject in every part. As these caused and cured cases of tuberculosis, though long made known in print, have not been upset, we will show that tuberculosis can be prevented by:

1. Special feeding, avoiding causal foods. This axiom needs no explanation, but for the once fashionable treatment on the principle of homeopathy that tuberculin is the cure for tuberculosis, meaning the treatment of results by results. But is it not a better principle to avoid the causes beforehand? Certainly this is according to everyday ethics and the Section on State Medicine, the keystone of whose arch is *prevention*. Avoid fire and there is no burning. I avoid the food that produces tuberculosis and I have *no* tuberculosis. Or, to put it differently and concretely, the 600 swine avoided the sour food of the 1,000 swine and hence did not have tuberculosis as the 1,000 had. On the rules of evidence these facts are not disproved. It must be admitted that healthy swine fed on good sweet maize and avoiding the vinegar slop of the 1,000 *did not have tuberculosis*.

But you say: "Men are not hogs." That may be, and yet there are lots of humans who are voracious hogs, making swill tubs and vinegar yeast pots of their alimentary canals, so that their feces have raised bread, a sample of which is in my possession, made at my instance, confirming the experiments of Salisbury. Said 1,000 swine could not help themselves. Men can. They can prevent tuberculosis by avoiding all foods that ferment with the common alcohol (*saccharomyces cerevisiae*) and vinegar (*mycoderma aceti*) plants. Such are all vinegars and vinegar liquids—starches and sugars in excess—all composite foods (made up of many articles) sweetened with sugar, glucose, maltose, levulose, frugulose; in fact any animal, vegetable or mineral foods that ferment with alcoholic and vinegar fermentation. Foods that ferment into sulphydric acid and phosphydric acid are admissible, but must be used so that they will not ferment, else nerve palsies will occur. The judicious use of hot water prevents these paralyzes by maintaining a downward peristalsis.

Celery, lemons, horseradish, butter, pepper and salt may be used as relishes. Hot water, clear tea, coffee and cocoa serve as drinks. Avoid corn-meal prepara-

tions, beans, soups, sweets, pies, cakes, pickles, sauce, preserves, fruits, vegetables, greens, pancakes, fritters, crullers, griddle cakes, salads and mush. Vinegar should be carefully avoided. This list is for patients, not healthy people; still it would be well to remember it.

2. General rule for feeding to prevent tuberculosis in healthy people: By bulk, two-thirds animal food to one-third food from the vegetable kingdom. Liquids at will, save sugars in excess. See "Food in Motherhood," E. Cutter: David Stott, 370 Oxford Street, London. Mothers on this diet, before and after pregnancy, have children with good constitutions. Lactation is full, free and not cut off prematurely. This is written advisedly. Children are a joy, not a sorrow nor nuisance in the house. Motherhood on this proportion of foods presents the most lovely spectacle seen on earth. Nothing more beautiful can arrest the gaze than a properly fed and kept motherhood, the "*ne plus ultra*" of domestic, social and "State medicine" bliss! Human beings thus raised will have the least tuberculosis. In fact, such constitutions will resist the invasion of tuberculosis by their very strength and integrity. Little fear would there be of tuberculosis by contagion or by infection, or the introduction of tuberculous matter under the skin of perfectly healthy animals. If so, then healthy kine tested with tuberculin infection would all have tuberculosis. Dr. R. L. Watkins was thus tested harmlessly a few years ago. Some unprotected persons have passed through life without having smallpox or measles, or scarlatina or diphtheria, though very much exposed. Even malaria needs a subject ill from malfeeding or some other depressing cause. The immunity of healthy nursing infants is a matter of observation. A perfect roof does not leak. Leaks come where roofs have solutions of continuity, *i. e.*, holes. A well made carriage goes over unhurt almost any kind of road, when one with loose bolts or tires or spokes, or cracked journals—to name no more—breaks down. Thus much for communication by *infection*. Now for *contagion* by the air.

Careful students of the morphology of the air realize what a vehicle the atmosphere is for all sorts of substances. Take the dust that gathers on top of railroad station advertisements for example. Most observers will readily agree that tuberculous bacilli or pavement epithelia invaded with bacilli or with the zooglea form or the mycelial form of the animalized mycoderma aceti, invade the air passages of almost every one, perhaps daily and hourly. The universal presence of alcohol in the atmosphere from decaying organic substances results from nature's means to rid the world of unused and useless fruits and vegetables, else we should live in a vast charnel house defiled by dead and dying organic substances. So that as vinegar is made from alcohol by artful use of air, it must be there are more or less vinegar plants in the atmosphere, and hence we must be more or less surrounded by aerial tuberculous bacilli. But sunlight and healthy secretions destroy these bacilli, or form a sterile nidus or soil for them wherein they do not develop. Hence the healthy body offers no habitat for this or other noxious vegetations. So we return to where we started from, to-wit, that proper feeding immunes from tuberculosis.

Domestic contagiousness of tuberculosis is explained by the fact that families generally live on the same foods now known to be causal, and the reason why all do not die is that some members resist more

than the decedents. Lawn hose pipes do not go to pieces all at once like Dr. Holmes' famous "one horse shay," simply because their structure is not homogeneous, but weaker in some points than others. For one, I do not think that the average healthy person contracts tuberculosis by inhaling dried or other consumptive sputum. For something like twenty years, I have studied such sputa, *con amore*, with an Amici pattern microscope where my breath constantly passes over tuberculous expectoration. I have no consumption of the lungs. And this, too, when during childhood and youth I was disabled by consumption of the bowels! Had I lived on the foods here laid down to be avoided, doubtless I would have contracted lung tuberculosis, and dying might have served as a fine example of the contagiousness of tuberculosis by inhalation! To me the State legislation proposed for the seclusion of consumptives is unwise, because I believe that simple, plain rations of wholesome food can stop the dissemination of this disease. As to contagiousness by the alimentary canal, it may be said that all tuberculous food cooked to a temperature of 212° F. will destroy its power by coagulating the albumin of the germs, so that they will not propagate on a favorable soil any more than bread baked at 285° F. and showing automobile bacteria afterward, will raise dough. (See essay on "Leavens and Man" in archives of the Philosophical Society of Great Britain, deposited 1882.) Were it not for baking, common bread, eaten as dough, would soon produce tuberculosis of all eaters. It is a wonder that pumpernickel bread does not kill more Germans.

Finally, since air food is eaten about twenty times a minute during man's existence, since air is so vital an article that we are named "animals," and since our beloved and honored Dr. Lewis A. Sayre found that forced respiration cured cases of lung tuberculosis (and some tell the same story for vocal culture), *go in for air food* freshened by sunlight and purified by the winds of heaven. Let patients take in full breaths of such air. Have the whole lungs, apices and all, fully expanded. Keep the lung capillaries well dilated by easy voice culture or by the passive effect of music, as shown by Professor Doziel, of Kazan, Russia. Feed the right solids, semi-solids and liquids. Maintain good hygiene and thus do much to prevent tuberculosis in a common-sense, rational way.

120 Broadway.

HYPNOTISM NOT A GAIN.

BY H. L. GREEN, M.D.

MT. PLEASANT, IOWA.

To the ordinary orthodox medical student the production of hypnotism may immediately arouse the thought of some tangible, comprehensible agent, such as chloral, chloroform, ether or sulphonal, something if not ponderable and palpable, yet perceptible in some way. The laity generally ascribe the power of the hypnotist to an imaginary animal magnetism. Electricity, which has been classed imponderable, can be felt; and why also should not this claimed potency have its volts and milliamperes? To the scientific student or psychologist this vague claim is too mystic, savoring too much of the imagination and is found in the present onward trend of knowledge, not to have a sufficient basis. Hypnotism, in the opinion of the writer, can mean only a more or less perfect sleep having

its expression primarily in the condition, physiologic and pathologic of the brain and nervous system; secondarily in other parts of the body system. The mind is not dependent, be it understood, on the brain alone for its seat but on the ganglionic system as well.

The physiologic and pathologic state of the mind may be illustrated in dream phenomena. Why not approach this subject through that of dreams as well as any other way? These have not in our day the same importance and significance they had when they determined the conduct of kings and the fate of nations. Dreams are apt to resemble the thoughts of the day or days immediately previous to them, or sometimes of a more remote period, and things which are familiar objects of thought or of observation of the times; in other words our night thoughts, occurring as they do when our mental control is partially suspended, are very much outlined and colored by the scenes and events of the wakeful day.

A person retires and falls more or less soundly to sleep. His brain, with most of its departments and cells, goes into a complete repose. A few cells, however, may continue to act, or keep up a limited activity the product of which is called a dream. The thoughts composing it may be as disconnected as the cells are disassociated. One idea suggests another; a single thought calls up a whole scene, a mental picture like unto reality. Since our controlling judgment is suspended, time and distance are annihilated. The dreamer blindly follows suggestion across oceans and continents; even decades and centuries present no obstacle.

Now this self-same suggestion is the magic word of the hypnotizer. Suggestion is more of a stimulant than depressant to the cells of thought. Through the agency of suggestion the performer makes an ally of the subject in overcoming the latter's will, disturbing and further widening the chasm of cell harmony and activity. The sensory centers may, as well as other parts of the brain, be affected and influenced in the same manner.

The writer knows an instance where an individual was so far affected that with his unaided hands he could and did tear out his testicles without the pain causing him to desist. It is well known that a speaker or performer has the advantage over an individual in the audience. The latter, even if opposed to the representations of the former, may have no set line of argument or tactics or rebuttal, whilst the former is loaded. This need not necessarily be so, but embarrassment one way or another, condition and circumstantial facts of the individual, and sometimes knavery, go to help out the operator. It is well known the foregoing conditions of the nervous system have their influence on the solids and fluids of the body, even to the constituency of the blood. Running thoughts in a general conversation suggested by one subject to another, is a good illustration of suggestion, and some of these running thoughts in a given seance taking on their natural or unnatural expression in acts constitute the gyrations of the hypnotic subject.

The relation of hypnotist and subject may now be not unaptly described in the words of an Irishman who said to the writer: "The Irish are so thick in Ireland they can hear each other think." But perhaps the best illustration of suggestion is given to us by Rabelais in "L'Episode des Moutons de Panurge," in which he relates that on a sea voyage Panurge to get even with the merchant, M. Dindenaut, who had injured him gravely, bought of him one of his sheep

and threw it overboard into the sea. The example and bleatings of this sheep drew in all of its companions, which in line precipitated themselves one after another into the sea. The merchant himself was drawn in by the last one, which he tried to retain, and was himself drowned with his flock; they were all lost: *l'extravagance imitative de la foule*.

The expenditure of much of the energy (Might we not say waste of energy?) in hypnotism, if devoted to an effort for the discovery of a better hypnotic remedy, might result in a great boon to the profession and to the world at large. For the truth is the medical profession stands in great need of a better hypnotic medicine than we have. Indeed, we have comparatively few such remedies: hydrate of chloral is still probably in the lead as a clear hypnotic, but it requires considerable of a dose, with a taste by no means so agreeable as its smell and the danger line often very fine.

WHICH ANIMAL HAS THE MORE "COMMON SENSE," MAN OR BEAST?

A PLEA FOR MORE MODERATE LIVING.

Read before the Academy of Medicine, at Syracuse, New York
May 21, 1895.

BY GEO. A. EDWARDS, M.D.

SYRACUSE, N. Y.

For what is man living? In the scale of being he is supreme; endowed in the highest degree with the wonderful power of reason—intellectuality, and clothed with responsibilities affecting nothing less than the future of the human race. In view of this, I assume it to be fit and proper to interrogate after such manner.

For what are *you* living? Stop, for a moment, the average, practical man of to-day, no matter what his profession, trade or calling, with this query. After a little confused reflection, he will very likely exclaim: "I'm blessed if I can tell: I believe I know less and less every day I live: haven't accomplished anything of moment thus far in life, and the issue of all my present aims and undertakings is uncertain; I reckon, sir, I'm just about a total failure."

Yet, this man is fairly well educated, bright and intelligent, a hard worker, enjoys some of what he terms pleasures and comforts, presents a good appearance, and is deemed, as the world goes, quite successful.

Pressed further and more closely for a true and thoughtful response to the question, and he will finally admit that he is living and laboring for the *means* which will enable him to satisfy his desires.

Living and laboring to satisfy his desires! And they are very many. Goaded by the "spirit of the times," with all its evil fashions, customs and habits; a loose rein, perhaps, on his appetites and passions; poisoned by selfishness, and envious of his more prosperous neighbor; he rushes on in the struggle, to win the empty prize of a false ambition; reckless of self and his dependents, with only delusive hope to cheer him on his way. And so this life continues to the end. Few achieve the goal of their longings, and if so, at what cost, with all their capacity for enjoyment gone!

How did Heaven ordain man should pass his allotted time on earth; what daily plan decree? With all reverence, perchance some such scheme as this: Work, alternating with rest, and recreation through innocent and beneficial amusements; regularity in

habit of both mind and body; moderation in all things; "friendships, content, progressive virtue, and approving conscience."

Is this an extravagant and ideal design for man's temporal sojourn? No; experience teaches its practicability, truthfulness and value; "common sense" will indorse it; reason, surely, should commend and proclaim it.

But does the boasted civilization and enlightenment of this almost the dawn of the twentieth century of our Christian era, preclude any approach to such an even-tempered, sensible existence? Alas! it seems too true. And must we roll back "the tide of years to the life led by primeval ages," or, bitter humiliation,—look down in the scale of creation for an example of a well regulated life? Let us see.

It has been well and truly said that we are living in the age of electricity,—the synonym of all that is intense and rapid in mental and physical activity. The "vital spark" has, indeed, enabled us to "girdle the earth in forty minutes," a prophecy more than fulfilled. The sea and land may pay tribute to commerce. Giant strides are being made in most of the arts and sciences. The genius of invention and discovery, twin offspring of supreme creative power, is gradually subduing the earth to man's domain and will. In the fine arts, painting and sculpture are transforming all animate life into imperishable images of striking naturalness.

And the art divine, music, "born with the morning stars," man's solace and charm, seeks to soon complete her tender sway by bringing all the flying discords into tune.

Wherefore all this intellectual activity and progress? Oh, it is simply an index of human development, the higher civilization of the times! But how does it profit man's physical well-being? To become a factor in such an economy of existence must he sacrifice health, long life, and entail his infirmities upon successive generations? Let us particularize for a moment.

The merchant, or, it may be, the manufacturer, with inordinate selfishness and greed, anxious to outstrip his neighbor, and assuming upon ill-advised conditions great financial responsibility, we frequently see mourning over his losses and with blanched countenance tossing upon his pillow the livelong night from the specter of a large note due on the morrow, with no money in the till to meet it. All this followed by loss of appetite, indigestion, and probably a fit of nervous prostration.

The banker, or broker, is ever lost in the whirl and din of the exchanges, until he is or well nigh, a fit subject for the mad-house, asylum for paretics, or a victim to apoplexy.

The traditional artist, chained to poverty, struggling after reputation, often faints, ever suffers, and betimes dies by the wayside.

Your statesman, possibly, reaches the topmost round in the ladder of fame, but at great expense, certainly, to his moral sense, from the practice of strange political methods for advancement, and finally exclaims: "It's a bauble; emptiness!"

And to think of our favorite hero of a hundred battles (to borrow a subject from the early part of the century), dying in humiliating banishment, and with distressing disease, at the early age of 52, and in his last moments weeping that he can make no more crimson history!

Emperors and kings have become victims to the festive board alone.

What volumes of sad comment these few illustrations suggest, bearing so closely upon the health, happiness and longevity of mankind, and that may be justly charged to our super-civilized methods of living.

Why, there seems an insidious contagion abroad in the land, and to which we are all more or less susceptible, and which tends to stimulate humanity toward a brief lurid existence, crowded with work and worry and inordinately spiced with luxurious dissipation, as contrasted with a quiet, temperate, useful life, filled with happiness and content and rounded by a green old age with its soul-satisfying retrospection.

In this mad rush made by man after success, whatever this term may mean,—riches, fame, or what not, he can spare, strange to relate, no time to look after, or care for, what to him is of the utmost importance—his *physical condition*.

There is no methodical season for rest and refreshment of the body, so necessary to sustain its normal vital energy, and to the numberless ills which will ever supervene upon such a continuous round of labor and excitement, he gives very little consideration. And, yet, man is such a *rational* being!

Sleep, the necessary factor in the recuperation of the nervous system, is crowded out, virtually repelled, by business and professional engagements after working hours: innocent (?) amusements; social requirements; until exhausted nature rebels and, many times, issues her alarmingly peremptory orders. But, man is an *intellectual* being!

Man eats when he is hungry, or not hungry, any time, day and night, and what? Not always *simple, plain, nourishing* food! Drinks when he is thirsty, or not thirsty (especially on invitation), at all hours, and what? *Not always water!* Then there is that vile weed, tobacco; why, a brute will suffer death rather than receive it in any form, and yet man apparently can not do without it.

Oh, how wonderfully constructed, beautiful and valuable are man's reasoning faculties; "to know the right and still the wrong pursue!"

So with all man's superior (?) intelligence, by indulgence in food and drink, with utter disregard as to quality, quantity, or regularity, together with a continuous deprivation of sleep in proper season, and sensible outdoor recreation, is it small wonder that he suffers from such diseases, some one or all, at different times, as troubles with the digestive tract—dyspepsia, indigestion, bilious conditions, diarrhea, constipation, hemorrhoids, the various neuroses, neuralgia, pneumonia, rheumatism, gout, lithemia, alcoholism, the baneful effects of tobacco, impairment of the senses, especially vision, and indirectly or secondarily, affections of the kidney, particularly Bright's, diabetes, and degenerative changes in other important organs, the circulatory and nervous systems.

Now, strictly speaking, most of the common and prevalent diseases affecting man, and this is quite true of the brute creation, should occur, if at all, from accidental causes; that is, the acquisition thereof, be due to conditions he is ignorant of at the time, or beyond his control. He would then be an innocent sufferer deserving of some sympathy like his fellow, the brute, under similar circumstances, and secure and guiltless of the charge herein made.

Hence the statement can safely be made as a fact, which same I believe will be very generally acknowledged, certainly by physicians, that the diseases above mentioned, in a great measure at least, are acquired by man through faulty practices and methods of living or no method at all, and consequently by the non-exhibition of his reasoning faculties, to say nothing of the exercise of "common sense," supposed to be possessed by all humans.

Moreover, if the truth of this premise be recognized, all disease contracted under known conditions and circumstances is preventible. And so it follows that man himself virtually becomes the author of all the miseries of much of his own ill health and often the crime of untimely death: his own executioner, as it were. Ignoble being! for such he proves himself, representing a human paradox! in significant contradistinction to the "equine paradox," of which we have all heard, if not seen, and fulfilling the truthfulness of the common expression that "Man is his own worst enemy."

At the expense of a little digression, perhaps, may not the question be here well put, if it is not just as plainly injurious and suicidal for the well-to-do gentleman to overwork, or do none, overeat and undersleep, with the sure result of fatal disease following sooner or later, as it is for the poorly paid laboring man having, perhaps, a large dependent family, to seek the only relief and oblivion from his troubles and hopelessness in the flowing bowl of the dramshop, with the sequence of alcoholism, the almshouse and death? The manner of acquiring disease and court-ing death may not be quite so dignified and honorable in the one case as the other; but there is a similarity to the final issue, and about the same small amount of good sense displayed in each.

The question naturally arises: Why does not man, when the principles and practice upon which health and life depend are so plainly obvious, exercise his faculties to secure the desired result? Are the reasoning powers at fault? "Common sense," at all events, would seem to be sufficient to teach him the proper course to pursue, and he ought to have a little of this in his make-up.

After all, this incongruous element to man's mental equipoise may possibly be accounted for on the supposition that originally and at best he is provided with very little "common sense," but being easily susceptible to vast quantities of knowledge and nineteenth century wisdom, he rapidly becomes the educated fool—the worst of all fools. The latter, we know, always turn to excesses and die young.

Let us now turn for a moment to examine the beast, its chief characteristics and habits of life.

Physically there is no essential difference between man and the brute creation. Bone, sinew, muscular and nerve tissues, if examined macroscopically or microscopically are found to be identical. The vital organs and senses are the same, perform the same functions and serve similar purposes. Resolved into its ultimate elements, we find the same food sustaining life in the beast as in man; and under like conditions of causation, most of the diseases affecting the two or three higher orders of animals under consideration present the same clinical features.

Now the beast unless inhumanly interfered with and maltreated by man is proverbially healthy (always excepting accidental disease) and lives its allotted time. To be sure, the beast leads a somewhat more outdoor existence, and hence gets the benefit of more

pure air and sunshine. But man, I take it, has an equal privilege to appropriate more of these life-giving attributes and would, if he had enough "common sense" to take advantage of it.

In truth, I know of but one reason why man should not be as healthy and long-lived as the brute. It is this: civilization compels him to wear clothes! That he is immensely handicapped by this specialty I will freely admit. Yet, even with this great drawback, I shall still assert he has a fair chance to attain and preserve the strength of true physical manhood. Perhaps many of you do not realize what a curse clothing is to man—I mean as regards his physical well being. And for the benefit of those who possibly have never investigated this subject, I will relate in brief the experience of the missionaries Sterling and Bridges, men who have had much to do with civilising and christianizing the natural product of the *genus homo* in far off and almost unknown lands. It will serve to illustrate the point I wish to make and may be strengthen the seemingly audacious statement just made.

In 1869, Rev. W. H. Sterling, now a resident of Buenos Ayres, and Bishop of the Church of England for South America, established a mission with the Yahgans, a large, healthy and powerful tribe of native Indians inhabiting one of the islands near Cape Horn. He selected for his residence and labors Ushuaia Bay, a tiny settlement on the narrow channel which bounds Terra-del-Fuego on the South. Mr. Sterling subsequently returned to England to be ordained in the episcopate, and in 1870 his work at Ushuaia was resumed by the Rev. Thomas Bridges and wife, who still live at this little place, on the shores of Beagle Channel.

It is from the latter's experience I quote chiefly: "A tribe of Indians that lived naked in a climate where snow storms raged in every month of the year, was to be transformed into a community of farmers. A people who had in all their wonderful language of 40,000 words no term or idea of God or a future existence, were to be taught and Christianized. Instruction began. The Yahgans who would work were given food. Navy bread for breakfast, meat stew and hard-tack for dinner, hard-tack for supper, with refreshing drinks of milk and water slightly thickened with flour, and sweetened. Clothing was also supplied them as fast as the mission was able." This work continued regularly and finally in 1881, eleven years after Mr. Bridges began his work, "in spite of sterile soil such progress had been made, that the mission reported a Christian village, with cottages instead of wigwams, and an extemporized church in the midst. Much ground had been cultivated, and cattle, sheep and goats had been introduced. Moreover, every Yahgan wore clothes. Great was the change at Ushuaia Bay."

"The missionaries had some 'significant contrast' photographs taken, and they were reproduced in an English magazine. But a more marvelous change than anything photographed was even then in progress. The natives began to get sick. Then they died. The race had been hardy and vigorous. They had actually increased in numbers while living naked and smeared with grease from head to foot. But when put to work as farm laborers, and washed and clothed like white folks, they complained of being 'tired and sore' and they had to be nagged into working steadily. They had slept in the freezing rain, but now, if they sat down in their shirt-sleeves while at work, they caught cold that developed into fatal disease.

Consumption and pneumonia appeared and assumed frightful aspects. Little children that had been round-limbed and bright-eyed when naked in a canoe, were wasting rapidly away in excessive languor, though clothed in woollens and living in a warm house. They continued to waste and die and from that day to this, not one child, in dozens born, has survived its first year! Of a tribe 3,000 strong, healthy, hearty and happy, fewer than 300 can now be found." But I spare you, and will not press the moral of all this.

Passing on and to resume the argument, suppose we inquire if the brute really does possess "common sense"; that sense or faculty, which is recognized as the simplest action of the brain, the organ of the mind; in other words, we will say the lowest grade of reasoning power.

We have all seen, if we ourselves can not exercise a similar function, exhibitions of good, common, or "horse sense" as the expression goes, and no one I fancy will wish to deny this distinguishing characteristic to that noble animal of the *genus equus*.

Some may still say that the beast is governed by instinct. I do not know how most comparative physiologists of the present day speak on this subject, but it seems difficult to conceive how such a term can be justly used to express the power of comprehension so frequently manifested in the brute.

Even in the apparent automatism of lower forms of life, an occasional flash of intelligence is easily discerned, and as we rise in the scale of being, and witness in the brute creation positive evidence of the intentional adaptation of means to ends—the offspring of thought, we must here acknowledge reason as the governing and controlling power.

Professor Huxley goes further, and, in summing up on this subject, says (and I need not quote higher authority, if it were possible to do so): "I have endeavored to show that no elaborate structural line of demarkation can be drawn between the animal world (brute creation) and ourselves; and I may add the expression of my belief that the attempt to draw a psychical distinction is equally futile, and that even the highest faculties of feeling and intellect begin to germinate in the lower forms of life."

On the whole, we may safely declare every living thing to be endowed with sufficient intelligence to direct its individual efforts toward doing and obtaining what is needful for its safety and best physical good.

In all the varied forms of life on this great earth, each and every creature, with one exception, makes use of this priceless gift for the purpose just indicated. Why the "crowning work of creation" is the exception is an unsolved problem.

Now, if we are quite ready at this time to grant the brute even common sense, does he exercise it?

In the daily contact with our best friends, the animals (brute creation), how often is one seen to suffer from any ill effects whatever from over-eating? Very, very seldom. And many animals enjoy gormandizing as well as man. There must be some simple secret to account for their invariable escape from the "seven devils" of dyspepsia and indigestion. Can it be plainness of diet? If so, man will do well to make a note of this. I can not say precisely what the effect would be on the most sturdily specimen selected from among our dumb fellow-creatures; if it were senseless enough to indulge night after night in a bill of fare

consisting of ham sandwiches, lobster salad, escalloped oysters, cake, candy, pickles, ice cream, strong coffee, champagne, etc., and all in addition to its daily allowance of customary food and drink; but think it would "fetch 'em—the gripes," sure and quick enough.

Why, the incomprehensible, indestructible digestion of "McClusky's goat" (that much abused animal), would, I believe, be somewhat disordered by frequent repetitions of such a festive *menu*. But the brute creation does not commit such crimes against itself.

Again, did you ever see a beast that did not know enough to prepare and go to rest and sleep at night-fall, if it were allowed to do so? I pause for a challenge to this assertion. Oh, ye creatures of superior intellectual capacity, canst thou gather no moral from this?

As might be expected, animals with such regular and exemplary habits in eating, drinking and sleeping are seldom sick. Indeed, very rarely, I believe, unless by accident, or ill treatment.

What an amusing innovation it would be to learn that your horse had an attack of acute dyspepsia! Is it very common to hear of a cow suffering with nervous prostration? A dog with rheumatism? A sheep with diarrhea? And did anybody ever see a cat, no matter of what age and in any emergency of its feline life, when it was thought to be in great need of spectacles?

We might press the inquiry on this line much further, and endeavor to seek in creatures so clearly allied to us the diseases commonly affecting ourselves, but I am very certain the effort would be quite barren of results.

In the condition thus revealed of man by contrast with his fellow creatures, proud as he ever is of being chiefest in this world of life, would it be too humiliating for him to admit that he might gather lessons of much value to his physical happiness and well-being from the plain and simple habits of a lower order of animals?

And what, if any, are the axioms to be deduced from the argument, and which man should keep ever near to his counsel, if he would retain his health and be long lived? They are, seemingly, self-evident: he should live frugally; avoid intoxicants; seek sufficient rest and sleep at the proper time, and the more pure air and sunshine he can expose himself to, the better.

Furthermore, and to repeat a little old and true philosophy, he should remember and take warning, that even to be able to exercise good "common sense," he must have a healthy body. That "haste makes waste." That wealth begets luxury, luxury begets idleness, and idleness breeds crime. And, finally, that there is no ambition worthy to be cherished, which leads him away from a conscientious duty he owes to himself, his fellow-man and his Maker.

With your kind indulgence, I have conducted both sides of the argument of this discourse (if it can be dignified by such a title), in a simple (I am not bold enough to say humorous), yet truthful way, and shall ask still further for the extraordinary privilege of acting the part of judge, as well as of advocate in the controversy. So if appealed to for an opinion on the merits of the question as stated at the outset, "which animal has the more common sense, man, or beast," I must, in view of the preponderancy of evidence herein offered, in the shape of a formidable array of facts and of which we are all, perhaps, too familiar, decide in favor of the brute.

Still, I believe there is hope for man, if he has not much "common sense;" and trust the startling revelation you have so meekly and patiently listened to will cause no one to despair of his own condition, or think that the future promises less for the nobility of true physical manhood. For, in the language of another, we may be consoled by the reflection that, "there is still a vast gulf between civilized man and the brute." "The power of knowledge; the marvelous endowment of intelligible and rational speech; the conscience of good and evil; the pitiful tenderness of human affections; raise us out of all real fellowship with them, as a mountain top, far above our fellow-beings, and transfigured from our grosser nature by reflecting here and there a ray from the infinite Source of all Truth."

CALCIFICATION.

Read in the Section on Dental and Oral Surgery, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY R. R. ANDREWS, A.M., D.D.S., F.R.M.S.

CAMBRIDGE, MASS.

Calcification is a process by which organic tissues become hardened by a desposition of salts of lime within their substance. In the intercellular tissue and in the substance of the cells themselves, these salts are deposited by the rich blood supply always near. They are deposited in minute particles and in such fine subdivisions that it makes it difficult to demonstrate many of them even with the higher power of the microscope. The intercellular substance, either a protoplasmic or gelatinous fluid or semi-fluid, contains the lime particles. In it they change their chemic nature, uniting with the organic substance of the part and form small globular bodies which have been called calco-spherites; and these blending or coalescing into a mass form a substance called calco-globulin. This calco-globulin, which is a lifeless matter, has been deposited through the cells into a gelatinous substance, and in some cases into the substance of the cells themselves, where by a further hardening process, it becomes the fully calcified matrix. Most of us are more or less familiar with the experiments of Mr. Rainey, and later of those of Prof. Harting and Dr. Ord. But, as an essay on this subject would not be complete without a brief quotation, I introduce some of their experiments. "If a soluble salt of lime be slowly mixed with another solution capable of precipitating the lime, the resultant lime salt will go down as an amorphous powder, and sometimes as minute crystals." But when the lime salts are precipitated in gelatin or albumin, the character of the lime salts is materially altered. Instead of a powder, there were found various curious, but definite forms, quite unlike the character of crystals or powder produced without the intervention of the organic substance. Mr. Rainey found that if carbonate of lime be slowly formed in a thick solution of albumin, the resultant salt has changed its character, it is now in the form of globules, laminated like tiny onions. These globules when brought in contact with one another become agglomerated into a single laminated mass, it appearing as if the laminae in immediate opposition had blended with one another. The globular masses at one time of mulberry-like form, lose the individuality of their constituent smaller globules and become smoothed down into a single mass, or layer, and Mr. Rainey suggests as an explanation of the laminated structure, that the smaller masses have accumulated in concentric layers,

which have subsequently coalesced; and in the substitution of the globular for the amorphous or crystalline form in the salt of lime, when in contact with organic substances. Mr. Rainey claims to find the clue for the explanation for the development of shells, teeth and bone. At a more recent date, Prof. Harting took up this line of investigation and found that other salts of lime would behave in a similar manner, and that by modifying the condition of the experiment very various forms might be produced. The most important addition to our knowledge made by Prof. Harting lay in the very peculiar constitution of the "calco-spherite," by which name he designated the globular forms seen and described by Rainey. That these are built up of concentric laminae, like an onion, has already been stated, and Mr. Rainey was aware that albumin actually entered into the composition of the globule, since it retained its form even after the application of acid. But Prof. Harting has shown that the albumin left behind after treatment of a calco-spherite with acid is no longer ordinary albumin; it is profoundly modified, and is become exceedingly resistant to the action of acids, alkalies and boiling water. For this modified albumin, he proposes the name calco-globulin, as it appears that the lime is held in some sort of chemic combination, for the last traces of lime are retained very obstinately when calco-globulin is submitted to the action of acids. Now it is a very remarkable fact that microscopic glistening specks and globules are constantly seen at the edges of tissue where enamel, cementum, dentine or bone are to be formed or are forming. Robin and Magitot have described isolated spherules of lime salt as occurring abundantly in the young pulps of human teeth, as well as those of other animals, and Tomes suggests that perhaps all deposits of lime salts commence in this way. These microscopic, globular bodies have been called calco-spherites, and it appears as though some such process as described by Prof. Harting is transpiring within the substance of the tissues where bone, dentine or enamel is to be formed. It will be noticed that near this point of formation there is always to be found a rich, capillary blood supply, and from this the lime salts are given out. As I have said, near the forming matrix the tissue is seen to be full of these microscopic, glistening bodies, the minute atoms which are often spoken of as granules. The abundant appearance of these globules at the time of the formation of the enamel and their entire absence at earlier stages is to me an indication that the globules are an enamel substance, the matrix-forming calco-spherites, and following up their future confirms this. Many of them are so small as to be scarcely measurable; they are almost always spherical. The lower part of the cell toward the dentine contains the larger globules. The growth of the enamel rod once begun takes place by additions of these globules. I am convinced that the larger ones are composed of hundreds of the smaller ones, which have coalesced into the main mass. When enamel is commencing its process of calcification, if we examine carefully with high powers a tissue that has been properly prepared so that there shall be the smallest amount of shrinkage, we shall find in that slight amount of the enamel organ that is directly over the calcified point of dentine, in what remains of the stellate reticulum and in the stratum intermedium principally, a very large number of glistening points. Most of these are minute, micro-

scopic, in fact. They are the calco-spherites in process of formation, or rather, they are the minute particles of lime from the blood supply, changing their chemie nature as they pass into the protoplasmic juices of the part. These appear to be passing into the formative cells and these cells superintend their formation into enamel rods, that is, they are laid from the cell against the forming rod. Within the substance of the ameloblasts they are seen to be growing larger by the smaller ones coalescing with others. If at this point of their development the layer of enamel cells is pulled away from the cap of formed dentine, we shall see that the cap of dentine is everywhere covered with quite regularly formed globular bodies. If on the other hand, the layer of enamel cells is against the formed cap of dentine the masses are assuming block-like forms, as though taking the form of the future enamel rod. They appear to be in a gelatinous substance which is between the dentine and the enamel cells, and here, by an unknown chemie hardening process, they become the hardened columns of the enamel, as I have formerly described in a paper read at Berlin, 1890. In dentine the calcifying process goes on in much the same manner. The odontoblasts are merely masses of protoplasm, and appear to have no membrane; as is the case with the ameloblast, it has a nucleus at a point farthest from the calcifying matrix. In forming the dentine matrix, the odontoblast, or the pulp tissue through the odontoblast, gives out a rich gelatinous substance about as wide as the layer of odontoblast cells. Everywhere between the odontoblasts, as Mummery has demonstrated, is found a rich supply of connective tissue cells, whose function appears to be the forming of a net-work of connective tissue fibers into this gelatinous substance, this net-work seeming to be a scaffolding upon which the calco-spherites, which are to form calco-globulin, are to be deposited. Into this layer the odontoblasts are also superintending the placing of the minute globules which are within them, and which have been given to them by the rich blood supply found everywhere near their pulp ends. Into the gelatinous substance the globules form against the calcified matrix, where, fusing with others, they form a mass, entirely filling the gelatinous substance. This gelatinous substance with its mass of globules now becomes calco-globulin. By some natural hardening process, it then becomes calcified matrix, and thus another layer of calcified matrix is formed. We must remember that it takes a large number of sections to show these various stages of growth. Each section shows the picture at the point where death of the part has left it; another section will show another stage, and so on. In one section we shall see the odontoblasts against the gelatinous layer with the globules within it. Another section will show an entire absence of the gelatinous layer, with pear-shaped cells a little away from the calcified matrix and with portions of cells clinging to the calcified matrix found here and there, that look like odontoblasts. Another section will show the globular masses filling up the gelatinous layer just before a new layer of calcified matrix is formed. It is only by studying these various stages of growth that we can come to any correct conclusions. In the cementum, a tissue I have not studied as carefully as I have the others, I am convinced that the calcifying process is much the same. The first cemental calcification takes place by the cementoblasts giving off these globular bodies near the neck

of the tooth against the forming dentine of the root, into a gelatinous substance, this also being given off by the cells. It assumes the form of plates or scales. Afterward the cells themselves appear to fill with the globules and lose their identity in the forming matrix. That peculiar tissue which we call "tissue on the borderland of calcification" is composed of globular glistening bodies which have coalesced and formed a layer within a gelatinous substance previously given out by the formative cells; in this condition it is a tissue indestructible both in acids and in caustic alkalies, and only in this condition is it true calco-globulin. The conclusions here given on the subject of calcification are arrived at after many years of original investigation, made at such times as could be spared from a busy professional life. They are, I believe, with slight modification, accepted by most of the more recent authorities. It is my object to have presented my views in as clear and simple a manner as possible, that I might enable those of us who are not intimately familiar with the natural processes concerned in calcification to form a clear idea, that they might draw their own conclusions as I shall review very briefly some of the, to me, erroneous views presented in a very recent work. I refer to a work entitled "The Anatomy and Pathology of the Teeth." The author and his associates, in a chapter describing "The Calcification of the Enamel" make these statements. They observe "that the more we turn to the center of the cup [enamel organ] the more shall we be struck by the presence of glistening, homogeneous lumps in the epithelia, until we have reached the center of the cup, where we observe that epithelium has been transformed into a number of such lumps in a regular arrangement, which reminds us of their origin from previous epithelia. The original epithelia [enamel cells] gradually become enlarged and are at last split up into a number of medullary corpuscles." "Medullary tissue develops into connective tissue of a decidedly fibrous character." "There is good reason for the assumption that the medullary tissues sprung from the previous external epithelium [of enamel organ] is the source for the completion of such enamel as we observe upon temporary teeth when they emerge from their sockets." And again, "if we examine the lower edge of the cup of the enamel organ at about the sixteenth week of embryonal life, we observe a peculiar change in the columnar bodies of the internal epithelium, which consists in the appearance in a more or less row-like arrangement, of highly-glistening globular bodies, replacing the previous columnar epithelia. These bodies are either solid or slightly vacuolated and are formations of living matter such as we are accustomed to look upon as medullary, embryonal, or indifferent corpuscles, in their earliest stages of appearance. Obviously, these glistening globules have originated from the reticulum of living matter of the columnar epithelia [enamel cells] themselves. We feel justified in this conclusion from the fact that we can trace step by step the growth of these glistening granules up to the formation of glistening lumps such as we have termed medullary corpuscles. . . . The lumps, I wish to repeat, are extremely glossy, with a high degree of refraction. They are arranged at first irregularly in a layer of considerable breadth, and higher up in rows, and by their coalescence and prolongation give rise to small columns, the ameloblasts. . . . These [medullary] corpuscles or the liquids

contained in their reticulum become solidified into basis substance and immediately infiltrated with lime salts. . . . "The enamel rods are built up of rows of such calcified or petrified medullary corpuscles."

These observers in regard to the calcification of the dentine endeavor to show that the odontoblasts are split up at their distal ends into these glistening bodies which they call medullary corpuscles. "These medullary corpuscles are lumps of protoplasm, in which living matter is stored up in different shapes, the glistening globules of small size having arisen from protoplasm, and that these represent a juvenile condition of living matter in its most compact aggregation which enter directly into the formation of the basis substance of dentine, while at the same time, continually superadded to the proximal ends of the odontoblasts are medullary corpuscles derived from the living matter of the papilla. Thus the continuity of the odontoblasts in dentine is established." They assert a similar proceeding from the ameloblasts, in a reverse direction. Thus, the ameloblasts being broken up at their proximal [dentine] ends into medullary corpuscles, which are directly transformed into blocks of enamel rods, are superadded to at their distal or peripheral ends by medullary corpuscles derived from the stratum intermedium. "The indifferent corpuscles serving to supply additions to the ameloblasts, exhibit all intermediate stages between small, globular, glossy and compact nucleated, protoplasmic lumps." "Nothing but a transmutation of solid, globular lumps of living matter in delicately reticulated medullary corpuscles seem to be required for the building up of the minute blocks of the enamel rods without the intermediate stage of ameloblasts. . . . The first appearing enamel is made up of irregular, angular, glistening lumps, greatly varying in size."

In these few selections from a chapter in this work on "Calcification," I have given some of the points which they present, and these I propose to briefly review. No one can be more clearly aware of the patient and persistent effort, and of the immense amount of labor and earnest research which the author has given to his work than myself, and great credit from his profession is due to Dr. Bodecker for this labor. I am not in accord with his views as to calcification of the dental tissues or the views of his master, Prof. Heitzmann, or of Dr. Abbot, on this subject. To some of us, "the reticulum" and the "medullary corpuscles" are bug-bears. We are familiar with, and have had many a conflict over these peculiar theories. To the earnest investigator who did not know the author, it would seem from their description of the calcifying processes, as if a tissue had been built up to fit a theory. So far as I am aware, photo-micrographs of these tissues, as described in this chapter on calcification have never been shown. There is no absolute evidence to prove the correctness of their assertions. Heitzmann, as an illustrator of histologic or pathologic tissue, is an artist, but however beautiful these drawings may be, the photo-micrograph is the picture with the stamp of truth that is convincing. The charge of "personal equation" could not be made in such an illustration.

In the May *International Dental Journal*, Dr. F. A. Roy, one of Heitzmann's students, writes to the editor, thus:

"In your review of Bodecker's book, you charge that there is no real evidence to prove the correctness of the theories advanced; and that the views are based solely on drawings in which

the personal equation is a prominent factor, for the drawings are all by Heitzmann. And you state that 'drawings, however beautifully done, can not carry conviction. A few photo-micrographs could have accomplished far more.' Also, 'it leads to the suspicion, whether justly founded or not, that either the slides can not be represented or that they have no real existence.' And 'it would seem that no expense should have been spared to meet this demand.' . . . A section must necessarily be examined at high powers of the microscope in order to see the reticulum. But no photograph yet produced of a section at such high powers can show what the eye can see. Even the thinnest section has a thickness that is very great when magnified by a high power, and the filaments of the reticulum do not lie on the surface, nor all in one plane but are in planes at immeasurable angles with the line of sight. The reticulum is not an open network, but is imbedded in a material not altogether transparent. We hope at an early day to succeed in making a photograph just as the drawing is made, by composite action of a number of negatives at different focal distances. Then we will have some astonishing revelations, such as we have synthetically in Marey's, or the kinetoscopic photographs of objects in motion. Certainly with the wonderful improvement in high power microscopes and in rapid photography the correct combination will come soon. Meantime Heitzmann's master drawings are not only better, but better evidence than present photographs. Heitzmann's answer no doubt is the only correct one—come and see. Come to his laboratory and learn how to see. Anyone who is unable to see the reticulum does not know how to see it. He that will not accept Heitzmann's drawings will not accept even the coming photographs, and probably he that will not accept these evidences is not willing to go to the expense of time and trouble to learn how to see for himself; certainly that individual expense should not be all saddled on Heitzmann or Bodecker, *et al.*

(Signed)

F. A. Roy."

I have made a quotation of this letter simply because I wish to show you on the screen to-night that it is possible to photograph any reticulum which was to be seen, if it were there. This reference to a composite photograph is to me very interesting; such a process, in my judgment, can never be effected. Besides it does not seem necessary. With our present knowledge we can show anything that is to be seen. Some years ago Professor Heitzmann and his New York friends were said to have gone to considerable expense in procuring an electric lantern with which they were to show the reticulum. It is now something over four years, and nothing has been shown confirming their peculiar theories. In fact, a denial of the existence of Heitzmann's reticulum comes to us from the best European authorities. This we shall find, among others, in Butschli's work on "Protoplasm and Microscopic Forms," a recent standard work of great value on this subject; and there are others. The whole chapter of Bodecker's work on "Calcification" is decidedly out of harmony with the teachings of modern investigation, and it seems to me to have been hasty and unwise on the part of the Association of Dental Faculties to have recommended this work as a text-book to the students of our colleges at this early date, especially as the work has no practical value. To one who is familiar with the subject, it is extremely doubtful that the glistening homogeneous lumps seen in the epithelial layers of the enamel organ have their origin in the reticulum of living matter of the epithelial layers, and it yet remains to be proven that this epithelium does split up into a number of medullary corpuscles of a fibrous character, and then become formations of living matter. It is an assertion that can not be proved true; that these glistening lumps, by coalescing and prolongation, give birth to the ameloblast. No; their so-called lumps of living matter—their medullary corpuscles—are but masses of a lifeless lime matter known to be calco-globulin. These masses are not medullary corpuscles;

they do not arise from protoplasm, nor do they represent a juvenile condition of living matter in its most compact aggregation. I wish to repeat: their medullary corpuscles, as represented in their illustrations, are nothing more nor less than lifeless lime globules, having nothing whatever to do with the origin of the ameloblasts. Years have passed since the peculiar views of these authors have been given, yet they have never been accepted by any acknowledged authorities. On the other hand, there are many who regret the action of the Association of Dental Faculties recommending to our students a work that has no practical value, as a text-book; a work of new and strange theories, as yet doubted and unproven; a work that will only mislead and confuse the earnest student searching for the truth. The work has a value, a great value, perhaps; but it is not for the student; it is solely as a work of reference and comparison in the library of the investigator.

INTERESTING CASES OF PERINEAL SECTION, WITH REMARKS.

BY G. FRANK LYDSTON, M.D.

PROFESSOR OF SURGICAL DISEASES OF THE GENITO-URINARY ORGANS AND SYPHILOLOGY IN THE CHICAGO COLLEGE OF PHYSICIANS AND SURGEONS; FELLOW OF THE CHICAGO ACADEMY OF MEDICINE, ETC.

During my seventeen years' experience in surgical work, it has been my fortune to perform a large number of external perineal sections. Among them, as might naturally be expected, operations for serious deep strictures have preponderated. I have selected from my cases a series of the most interesting of which I have records. Some of the most interesting cases have not been recorded because of various circumstances surrounding the operations which have made it at least impracticable, if not impossible, to do so.

I will first present the cases in their salient features, reserving my comments for the conclusion of the article.

Case 1: Traumatic Stricture. A lad, 15 years of age was brought to me by his parents with a history of urinary obstruction dating back one year. There was no history of gonorrhea, but of a blow upon the perineum, received some fourteen months prior to his consulting me. This injury was not followed by hematuria, but the perineum, it was claimed, was slightly swollen some days after the accident and there was a little difficulty in micturition, not sufficient, however, to necessitate medical attention. The obstruction to urination had entirely disappeared until about two months after the injury, when a slight increase in frequency and slight obstruction were noticed. This had increased to a mild degree until within three months, when an attack of retention came on. This was relieved by the passage of a catheter, but had recurred at intervals of three or four weeks since that time, the caliber of the urethra meanwhile rapidly getting smaller, until at the time of his consulting me I found it impossible even to pass a filiform into the bladder. Perineal section was proposed and performed a few days later. Much to my gratification I found that a few days of preparatory rest, restriction of diet, the administration of urinary antiseptics put the urethra in such a condition that I was enabled to pass a filiform at the time of the operation, thus simplifying subsequent operative procedures. The urethra was restored to a caliber of 30 French, a preliminary meatotomy being necessary for this purpose. The patient was up and about at the end of ten days, the perineal wound being soundly healed at the end of two weeks. Patient has since carefully followed directions regarding the introduction of the sound and is now thirteen years after operation in excellent condition.

Case 2: Irritable Gonorrheal Deep Stricture of Long Standing.—Referred by Dr. F. B. Norcom, of Chicago. Age, 40 years; occupation, conductor. Obstruction to urination of fifteen years, duration. Symptoms first noticed after a third severe attack of gonorrhea. No history of traumatism. Numerous attacks of retention had occurred, after which the patient

would have dilatation practiced for a short time. His habits since the beginning of the obstructive symptoms had been decidedly bad. Numerous attacks of more or less severe urethritis had been experienced since the beginning of the stricture symptoms. Dilatation was commenced at once, but was badly tolerated, each séance being followed by chill and fever. Perineal section was suggested and accepted.

As the stricture readily admitted a small guide, the operation presented no especial difficulty. The stricture was found to involve the bulbo-membranous and the larger portion of the perineal urethra. Especial care was taken to thoroughly divide the indurated tissue upon the roof of the canal. The meatus was freely incised and several senile strictures divided. When the operation was completed a 36 French sound passed easily into the bladder.

This case was last seen one year after operation and was then in excellent condition, there having been no recontraction.

Case 3: Irritable Deep Stricture with Remarkable Irritability of the Vesical Neck. Gentleman, 30 years of age, referred to me by the late Dr. A. Reeves Jackson, consulted me regarding an obstinate gleet with irritability of the vesical neck. There was a history of gonorrhea dating back some ten years. The attack, however, was apparently considerably aggravated by the patient's habit of indulgence in intoxicants. Examination shows that the penile urethra was of normal caliber, but all efforts failed to pass an instrument into the bladder. At the end of twenty-four hours another attempt was made, the patient meanwhile keeping perfectly quiet in bed. As the patient was desirous of avoiding a radical operation, attempts at dilatation were repeated at intervals of twenty-four to forty-eight hours for several weeks, with no results save the production of great discomfort to the patient. Perineal section was performed and the perineal urethra sufficiently enlarged to readily admit 35 French. Some little trouble was experienced in this case from hemorrhage for the first twenty-four hours, after which there was no further annoyance. The patient was last seen ten years after operation; the urethra was found contracted so that it would not admit a sound larger than 30 French, this size being quite satisfactory, especially in view of the fact that the patient had been somewhat careless and had had a sound introduced only at long and irregular intervals.

Case 4: Traumatic and Gonorrheal Stricture with Multiple Fistulae. Man, 45 years of age, referred to me for stricture involving the penile urethra at a short distance from the meatus and in the bulbo-membranous region. This stricture, originally traumatic, had become greatly aggravated by several attacks of gonorrhea. Numerous fistulae had formed in the perineum, one of which had burrowed into the scrotum. The stricture was hard and nodular, as is characteristic of traumatic strictures as a rule. As the patient objected to operative measures and attempt was made to restore the patency of the urethra by gradual dilatation. This comparatively mild measure, however, was a failure, and at each séance the patient's life was endangered by a typical attack of chill, fever and sweat. Eucalyptus was finally administered internally and the symptoms of urinary fever disappeared. The progress of the case under the dilatation method was so slow and uncertain that a perineal operation was decided on, the urethra being restored to a caliber of 39 French. No chills were experienced after the operation and the temperature did not at any time rise over half a degree. This patient was seen two years after the original operation, at which time the urethra retained its patency. The fistula to which allusion has been made healed kindly and promptly.

Case 5: Multiple Penile and Resilient Deep Stricture.—Man, 18 years of age, referred by Dr. F. B. Norcom, consulted me for difficult micturition, which was first noticed six months previously. There was a history of gonorrhea at 15 years of age, which lasted for nearly a year and was treated by very powerful injections, prescribed by an obliging druggist. No attacks of retention had been experienced. There had been a gradual increase in the urinary obstruction. Examination revealed a contracted meatus and two penile strictures at a depth of two and one-half and four inches respectively. The largest instrument admitted by the penile strictures was a No. 20 French. I succeeded with great difficulty in passing a filiform bougie. A faithful attempt was made during a period of nearly two months at gradual dilatation. The stricture, however, proved to be very irritable and resilient, and operation was finally suggested and consented to. Perineal section and internal penile urethrotomy were performed, the urethra being enlarged to a caliber of 35 French. The patient experienced a chill on the fifth day following the operation, a sound having been passed on the fourth day. This was followed by a moderate fever and acceleration of the pulse, which rapidly subsided and did not again recur. This patient was last seen

twenty months after operation, sounds having been passed at intervals of two or three weeks, after which the patient was discharged from my care. On exploration no recontraction was perceptible.

Case 6: Deep Perineal Stricture: Multiple Penile Strictures: Severe Cystitis, Vesical Calculus. Man, 53 years of age, with a history of urinary trouble dating back to the age of 15. First attack of gonorrhea had occurred at the age of 20. He stated that he had more or less blood in the urine at intervals, and frequent and painful obstruction long before he contracted gonorrhea. He also stated that the urine had contained more or less matter before he had ever suffered any urethral trouble. He had been treated by irrigations for chronic cystitis prior to the development of his gonorrhea. His bladder had been explored on numerous occasions, but with a negative result. Urinary obstruction began six or seven years before I saw the case, and it gradually increased, but had never become marked until about one year before, at which time an attack of retention came on which was relieved by catheterization. Within six months past he has had several attacks of retention, which were relieved in a similar manner. For several months he had had recurrent slight chills with fever, and was considerably run down in his general health. On examination I found it extremely difficult to introduce a filiform into the bladder. This manipulation resulted within six hours in a very severe chill, and although there were no further attempts made for several days, the chills followed by fever recurred. In view of the condition of the bladder and the possible existence of a foreign body, a radical operation was in my opinion the only thing to be thought of. The operation proved an easy one, and under an anesthetic I was enabled to introduce a good-sized guide into the bladder. After thoroughly freeing the urethra from contractions, I passed my finger into the bladder and encountered a calculus as large as a small plum. This was extracted without great difficulty and without further cutting. It was composed of a small uric acid nucleus crusted by the usual concentric layers of phosphates. After the operation a No. 35 sound was passed into the bladder without any difficulty, slight incision of the meatus being necessary for days. Perineal drainage was kept up in this case for four weeks, during which time the bladder was treated alternately by iodoform emulsion and irrigations with nitrate of silver. Improvement in the condition of the urine was remarkable. At the end of ninety days there was scarcely a trace of pus to be found. The perineal wound was soundly healed at the end of six weeks. It is interesting to note that in this case there were no chills or rise in temperature after the operation.

An interesting feature of this case is that four years later I operated on the same patient for appendicitis, which, as far as I know, completes his surgical experience up to date. I have seen this patient within a year, and his urinary apparatus is apparently in perfect condition.

Case 7: Deep Stricture with Multiple Fistulae.—Man, 45 years of age. Stockman: had experienced a number of attacks of gonorrhea, none of which had occurred within ten years. There was also a doubtful history of traumatism. Various attempts at treatment by dilatation had been made, with temporary relief. Peri-urethral abscess had developed some years before I saw the case and had left several fistulae, one of which involved the scrotum. The history of urinary obstruction dated back some fifteen years. For some time the patient had been rapidly failing in his general health. Attempt at exploration had been followed by chill and sharp "urinary fever." Urinalysis revealed nothing definite regarding the condition of the kidney, but more or less advanced disease of these organs was taken for granted. After careful preparation by dieting, baths and the administration of urinary antiseptics, perineal section was performed, operation without a guide being necessary. Ether was the anesthetic used. All sinuses were carefully followed out and laid freely open. Hemorrhage from small vessels was unusually profuse, necessitating the Paquelin cautery at some of the deeper points in the divided sinuses and fistulae. The urethra was found only after prolonged search, and at the completion of the operation the patient was greatly exhausted. He reacted fairly well, however, the urethra admitting 32 French and the perineal wound having closed, when, two weeks after the operation, anuria developed, uremia followed and death occurred within forty eight hours.

Autopsy revealed good condition of the operative field. The kidneys were pyelo-nephritic and showed evidence of recent acute inflammation. I will remark in this connection that death is often superinduced by the anesthesia, even where chloroform is given, but especially when ether is used, but the fatal result occurs so long after the operation that the real cause is overlooked. I desire to insist on this point, because we are often unfair to chloroform. The latter drug declares itself in speedy

and unequivocal fashion, as a rule, while ether often destroys life so remotely that the true cause of death is lost sight of.

Case 8: Man of 30; mechanic by occupation. Successive attacks of gonorrhea had been experienced, the last occurring one year before consulting me, and the first at about the age of 18. Stricture of the deep urethra developed at about the age of 25. Numerous attacks of retention had occurred and had been relieved with increasing difficulty. Two days before I saw him retention had come on and while straining violently to urinate he felt something give way in the perineum, after which he said he felt better for a time. On examination I was unable to get a guide into the bladder. The scrotum and perineum were brawny, discolored and infiltrated. Septic cellulitis was evidently impending. The temperature was 101.5 degrees F. and the pulse 120. The general condition was fairly good. Perineal section without a guide was at once performed and free incisions made into all swollen points. Several penile strictures of moderate caliber were left for future attention. Free drainage by iodoform gauze and perineo-vesical tube was provided for. The operation was well borne and the subsequent course of the case unexceptionable. There was some sloughing of the perineo-scrotal tissues, but the application of charcoal and iodoform poultices soon brought about a healthy condition. Three weeks later the penile urethra was restored to a caliber of 35 French. At the present time, two years after the operation, the patient easily passes a 31 French upon himself at long intervals.

Case 9: Impermeable Deep Stricture—Urethral Calculus.—The patient, a young colored man of 30 years of age, was referred to me by Dr. J. G. Reid, of this city, for operation upon a deep perineal stricture of gonorrheal origin. The stricture had existed for some ten years and during this time had given rise to attacks of retention from time to time, but there had been no serious difficulty of micturition until within a year. In operating on this case I found it absolutely impossible to pass a guide and was compelled to operate without it. The operation proved a tedious and bloody one, and I was seriously contemplating supra-pubic section and retrograde catheterism, when I succeeded in entering the bladder. The patient suffered from pronounced urinary fever for about ten days after the operation, the condition evidently being of a septic character. Recovery, however, finally ensued and the patient is now, a year after the operation, in good condition. Subsequent history unknown. At the time he was discharged from my care he took a sound of caliber 32 French with comparative ease.

An interesting feature in this case was a calculus the size of a pea which was found in the dilated portion of the urethra behind the stricture at the bulbo-membranous junction. It was composed of uric acid nucleus with phosphatic laminae. There was no history of renal colic; hence the stone probably formed in the bladder and lodging upon the stricture became enlarged by subsequent accretions of phosphatic deposit. Another noteworthy point was the extreme dilatation of the veins ramifying in the mucous membrane about the vesical neck, a condition which I have observed in one other case of a similar character.

Case 10: Impermeable Deep Stricture with Chronic Prostatic Abscess, Recontraction and Reoperation.—Gentleman, 45 years of age, referred to me by the late Dr. A. Reeves Jackson for the relief of retention due to surgically impermeable stricture in the perineal portion of the urethra. There was the usual history of a succession of attacks of gonorrhea, the most of which were in early youth, none having been experienced for some years. The urinary difficulty had existed for several years. There was a history of recurrent prostatic abscess. The patient's general health was considerably impaired in spite of a natural rugged constitution. Perineal section was suggested in this case, and the patient was afterward operated upon by his own physician with the assistance of several other surgeons of recognized ability. Some weeks after the operation I was called to see the patient in consultation, and found that it was with extreme difficulty that sounds could be introduced. As my experience has been that where sounds are difficult of introduction soon after a perineal section, reoperation is necessary, I made the suggestion to the attending physician, who not only accepted it but courteously turned the case over to me for operation. I operated a few days later and restored the caliber of the urethra from meatus to bladder to 36 French. The case did well and was discharged from the hospital at the end of about four weeks. No further trouble was experienced for several months, when the patient consulted me for an attack of acute retention of urine. A linear obstruction had reformed at the bulbo-membranous junction as a consequence of inattention to the passage of sounds after operation, the patient having been upon the road for some

weeks and compelled to neglect himself. It is possible that the recurrence was favored by several pockets which existed in the prostate as a result of the old-time prostatic abscesses. These pockets I hid open quite freely at the time of the operation, but on operating the second time I found that one was still perceptible, requiring a second division of its upper wall. An attempt was made to relieve his condition by dilatation of the stricture and irrigation of the bladder, but without success, retention with overflow coming on just as soon as the use of the catheter was stopped. Another operation was proposed and consented to. A very slight linear band was found at the point of obstruction and a reformation of one of the pockets was found to have occurred. The urethra was cut to a caliber of 40 French, the anterior urethra which had been freely cut at the previous operation having maintained its patency and taking without much difficulty a 40 French, although its caliber had been increased at the previous operation only up to 36. The urethra, however, was quite supple and the contractions which previously existed, having been removed, were readily dilatable up to 40. The progress of the case after the second operation was uneventful. The patient is now, some six months after the operation, in excellent condition. There is, however, at this time a slight tendency to recontraction, the patient having allowed himself to go two months without the introduction of a sound in spite of the most impressive warning of the danger of neglect.

Case 11: Irritable Deep Stricture of Large Caliber. This case presents some rather peculiar features. A man, 25 years of age, consulted me regarding an obstinate gleet which was found to be dependent upon several penile strictures. An obstruction of the deep urethra was also noted, but inasmuch as the stream of urine was alternately reduced in size and free during micturition, the deep obstruction was considered to be chiefly spasmodic. The entire urethra was exquisitely sensitive, so much so that it was not considered wise to attempt the passage of an instrument into the bladder. Internal urethrotomy was performed and the penile urethra restored to a caliber of 37 French. Within a week after the operation it was found that a 20 French sound could be introduced into the bladder, but the deep urethra was still quite sensitive and there was a distinct spasmodic grasping of the instrument by the deep urethral muscles during its withdrawal. Exploration with the rubber bulbs showed a distinct linear contraction in the bulbo-membranous junction. An attempt was made for a period of nearly three months to restore the caliber of the deep urethra by gradual dilatation, but without success. After nearly every introduction of the sound intense irritation of the vesical neck was produced. This vesical irritation could not be prevented or controlled by any method of treatment. The patient's gleet which had been very annoying continued, and perineal section was finally decided upon and performed with a most gratifying result. When dismissed a 35 French sound could be readily introduced into the bladder. I have not seen this patient since six months after the operation, but a letter received three years later informs me that a 30 French is readily introduced into the bladder, despite the fact that the patient has not been particularly assiduous in his care of the urethra. The gleet in this case proved quite stubborn and persisted for some months after the operation, but finally disappeared. The patient informed me that he has since had a slight attack of urethritis from indubitable infection, but that no recontraction of the urethra was noticed after its subsidence.

Case 12: Irritable Deep Stricture with Perinephritic Abscesses.—Man, 28 years of age, salesman. This man had an irritable spasmodic stricture for some years. The stricture was located deeply and was of gonorrheal origin, the patient having had several attacks of urethritis. The caliber of this stricture was by no means large, but it was so irritable and resilient, and the chronic inflammation and sepsis behind it were so marked that recurrent attacks of vesico-prostatic inflammation were experienced. I advised perineal section, which was refused, and I consequently did the best I could for the case by dilatation. I found it practicable to introduce sounds the size of 20 French, but all further attempts at dilatation resulted in chills and fever. This case subsequently underwent a most extraordinary course. A perinephritic abscess formed on the left side, and subsequently one on the right. These were treated by free incision and drainage, and were evidently due to infection from the deep urethra. Why the kidney should escape serious disease I am unable to say.

A similar case came under my observation at one time in which, through inattention on the part of the patient, there was a condition of suppuration of the kidney. This case was afterward operated on by Dr. Tiffany, of Baltimore, for double perinephritic abscess, and the patient eventually died from

some other condition which, so far as I could learn, was independent of the old-time genito-urinary difficulty.

Some time after the development of the perinephritic abscesses (in the case under consideration) the patient consented to an operation which was performed and followed by prolonged perineal drainage. The urethra was restored to a caliber of 35 French, several penile strictures of large caliber receiving attention at the same time, and meatotomy being performed. The patient was up and about at the end of three weeks, and when last heard from (one year after the operation) was in excellent health.

Case 13: Impermeable Stricture at the Penoscrotal Angle.—Application of the "String Saw" Principle to the Urethra. Man, 25 years of age, with a history of gleet of four years' duration. For about one year the patient had noticed obstruction to micturition; this had gradually increased until the stream became so small that evacuation of the bladder required from fifteen to twenty minutes with severe straining effort. Examination revealed in this case a narrow meatus and a tortuous stricture which practically occupied the entire penile urethra. The ballooning of the perineal urethra during micturition suggested that the obstruction in all probability originated at the peno-scrotal angle. After several attempts I succeeded in passing a filiform bougie. Retention followed and an emergency operation became necessary. Under anesthesia I attempted to pass a guide through the urethra for the purpose of performing internal urethrotomy, a proceeding which I found impossible of accomplishment, the passage of the instrument being obstructed at a point below the peno-scrotal angle. I proceeded to perform perineal section. I found the perineal portion of the urethra extremely dilated behind the obstruction a little anterior to the peno-scrotal angle. The deeper portion of the urethra was free from contraction. After repeated attempts I succeeded in passing a filiform bougie from behind forward. I found it impossible to pass the urethrotome upon this bougie as a guide without incurring the danger of serious injury to the urethral walls. It so happened that I had been recently perusing Dr. Abbe's interesting cases of division of stricture of the esophagus by means of a string, so the idea occurred to me that the same method could be adopted here. I therefore tied a silk ligature to the bougie and drew it from below through the urethra. Drawing the penis well up over the abdomen, I then proceeded to draw the string back and forth with a sawing motion through the stricture, with the result that in a few seconds I was enabled to draw the cord to quite a good size through the canal. A few seconds later the cord was withdrawn and the canal rapidly dilated with bougies until I could readily introduce the blades of the urethrotome. All of the contractions were divided to a caliber of 35 French. The subsequent history of this case was uneventful. The patient at the present time, six years after operation, is in excellent condition and passes a 31 French upon himself with perfect ease.

Case 14: Tortuous Perineal Stricture. Gentleman, 38 years of age, consulted me regarding a hard, tortuous perineal stricture. There was a history of a number of attacks of gonorrhea. The patient's habits were very intemperate and there was a distinct history of gout. The urine, according to this patient's account, had been from time to time loaded with urates and uric acid for a long period of years. Perineal section was performed without a guide being necessary, as not even a filiform could be introduced. The operation proved quite tedious. The caliber of the urethra was restored to 28 French. Convalescence was uninterrupted. The patient was seen two years after the operation and very little recontraction was found to have taken place, the urethra still admitting 35 French. Recent advices from this patient state that there has not been any further recontraction, the patient now being in excellent health.

Case 15: Resilient Deep Stricture of Moderately Large Caliber, with Fistula.—Man, 40 years of age, consulted me regarding a small perineal fistula of several years duration. The patient gave a history of several attacks of gonorrhea, the last of which had been experienced some four years before he consulted me. During the progress of the last attack of gonorrhea a small abscess had formed in the perineum. This was opened, much to the patient's discomfort, and it was found to communicate with the urethra. A permanent fistula eventually formed. There had been no marked obstruction to urination at any time, although the patient was subject to attacks of frequent and rather painful micturition. A moderate amount of gleet was present. Exploration revealed a contracted meatus and a hard resilient bulbo-membranous stricture of fairly good caliber. Systematic attempts at dilatation were made but without effect, the perineal stricture proving irritable and resilient and consequently resistant to treatment.

Perineal section was decided upon and performed, the caliber of the urethra being restored to 35 French. The patient was kept under observation for about a year, but no examination has since been made. At the time the case was last seen there had been no recontraction. The patient was in excellent health.

Case 16: Multiple Penile and Perineal Strictures. Young man, 24 years of age, was referred to me by Dr. J. N. Dixon, of Springfield, Ill., for operation for a deep urethral stricture which had become obstinate and intractable. Exploration revealed several strictures in the penile urethra and at the meatus in addition to the deep contraction. Although persistent efforts were made, even filiform bougies failed to pass for some days, during which time the patient was kept confined to his bed, rigid dietetic precautions being taken and hot sitz baths prescribed. When the operation was finally performed there was little difficulty in getting a small guide into the bladder. The normal urethra in this case was very large, and perineal contractions were enlarged to a caliber of 40 French. The subsequent course of the case was very favorable, and when the patient was discharged from the hospital he could still take a caliber of 38 French. At the present time, about two years from the date of operation, there has been no recontraction.

Case 17: Resilient and Irritable Perineal and Penile Strictures with Urinary Fistula. Young man, 24 years of age, consulted me regarding a stricture which he referred to an attack of gonorrhea experienced at the age of 18. Several slight attacks of urethritis had occurred since. On inquiry a doubtful history of injury at the age of 15 was elicited. Examination in this case showed a stricture just within the meatus and a surgically impermeable contraction at the bulbo-membranous junction. There was a small fistula at the perineo-scrotal angle, which could be traced back to the bulbo-membranous region by exploration of the tract with a filiform bougie. Being desirous of avoiding a cutting operation the patient submitted to frequent attempts at dilatation of the stricture for several weeks, at the end of which time a filiform bougie was passed. I succeeded in dilating the stricture up to a caliber of 10 French, when it became very irritable and resilient. All attempts at further dilatation caused more or less sharp attacks of urethritis with coincidental urethral chill. An operation was suggested and consented to. The case was cut to a caliber of 36 French. This case was seen at the end of a year and no recontraction had occurred, the patient passing from 30 to 34 French upon himself without the slightest difficulty.

Case 18: Extensive Deep Cicatricial Stricture with Multiple Fistulae. A man, 40 years of age, referred to me by Dr. E. P. Murdock. This case was referred to the Railway Brotherhood Hospital for surgical relief and was kindly referred to me. There was a history of numerous attacks of gonorrhea, none of recent date. Numerous urinary abscesses had occurred in the perineum with the usual resulting fistula. Perineum was hard and almost cartilaginous in consistency throughout its entire extent. Several fistulae had burrowed in various directions, some of them appearing as far back as the ischio-rectal fossa upon one side, upon the other a fistula was present burrowing well out upon the nates. The penile urethra was free from contractions except at the meatus. Treatment by gradual dilatation was not to be thought of in this case, hence perineal section was determined upon. Under ether I succeeded in introducing a small perineal guide with a central groove, this greatly simplifying the operation. The stricture was found to involve practically the entire perineal urethra down to the bulbo-membranous junction. Free division was made, the roof of the canal being found to be extensively infiltrated by cicatricial deposit. The fistulae were laid freely open, and a large-sized sound was now readily introduced into the bladder. On the fourth day after the operation examination of the perineal wound showed several bridges of cicatricial tissue upon the roof of the urethra which had escaped division. These were freely divided. The subsequent history of the case was uneventful and the rapidity of healing was quite remarkable considering the extensive incisions which were demanded by the fistulous tracts in various directions. I have not heard from this case since he was dismissed from the hospital, at which time Dr. Murdock informed me he was in excellent condition.

Case 19: Multiple Perineal and Penile Strictures. Man, about 45 years of age, patient of Dr. P. H. Anderson. This patient had had numerous attacks of gonorrhea with resulting intractable penile and perineal strictures. At the time Dr. Anderson called me in consultation the patient had been troubled for some days with attacks of retention, which were relieved with extreme difficulty. There was some elevation of temperature, and while it was possible to introduce very small

bougies, the stricture was so hard and cartilaginous and the danger of urinary fever apparently so great that I believed perineal section to be the wisest course. This was accordingly performed and the urethra restored to a caliber of 35 French. The operation was not attended by any particular difficulty. Dr. Anderson informs me that considerable fever followed the operation. The case finally recovered, but after a somewhat tedious convalescence. I understand that at the time the case was dismissed by Dr. Anderson it was possible to introduce sounds of fairly good size. The present condition of the case is unknown.

Case 20: Impermeable Deep Stricture, Secondary Suture of Perineal Wound. Man, 40 years of age, referred to me by Dr. Van Riper, of New Carlisle, Ind. This case was distinctly traumatic, being referable to an injury experienced at about the age of puberty. There was a history of recurrent attacks of retention, and from time to time mild attacks of urethritis. The patient had greatly emaciated and was suffering from pronounced urinary fever. Experience had shown the futility of dilatation, and perineal section was suggested. It was found impossible to introduce a guide even under anesthesia. The meatus was contracted and a deep stricture was found in the membranous urethra. There was a moderate amount of difficulty in finding the proximal portion of the urethra after opening the perineum. After a somewhat tedious dissection, however, this was accomplished. The urethra was restored to a caliber of 38 French. The patient did badly for a week or ten days after the operation, and the wound was very slow in granulating. At the end of three weeks a permanent fistula (perineal) seemed to be highly probable. Two silkworm gut shotted sutures were therefore introduced into the perineum, bringing the sluggish granulating surfaces in close apposition. A retained catheter was placed in the urethra for forty-eight hours, at the end of which time it produced so much vesical irritation that it was removed. Not a drop of urine escaped via the perineal fistula after the suturing, and within a week the perineal opening was soundly healed. At the present time, four months after the operation, I find a 35 French passes with great ease. The patient has regained his health and strength. This case aptly illustrates the serious constitutional disturbance which sometimes result from pronounced stricture.

Case 21: Deep Stricture with Retention.—Young man, 23 years of age, occupation laborer. This patient denied venereal infection. He stated that he was thrown from a wagon at the age of 18 and landed in a sitting position upon some rocks that lay in the roadway, which was followed by bruising of the buttocks and perineum. The buttocks were severely contused, but according to the history there was a moderate amount of perineal swelling and ecchymosis. The urine was passed with moderate ease for the first two or three days. After the operation inflammation and additional swelling of the injured structures came on, with a resulting attack of retention. This was relieved by the introduction of the catheter several times daily for about ten days, after which the urine was passed in the normal manner. Sounds were not passed subsequently until urethral obstruction developed and the patient found some difficulty in passing water. Instruments were passed thereafter at varying intervals, but with increasing difficulty and of smaller size. At the time the patient consulted me it was found impossible to pass anything larger than a filiform. The urine was trickling away constantly. For several months the patient had experienced a chill, followed by some fever, which came on every day or two. The temperature at the time I first examined him was normal. The anterior urethra was found free of obstruction, the meatus being more than ordinarily capacious. Perineal section was advised. Under anesthesia a moderate degree of dilatation was secured, and as a consequence it was found possible to introduce a grooved guide of moderate size, upon which the stricture was freely divided with no difficulty whatever. There was found to be a considerable amount of cicatricial tissue impinging upon the roof of the canal. This was freely divided, the urethra being restored to a caliber of 35 French, which was approximately the patient's normal size. The usual course of after treatment was resorted to. The patient was heard from six months after the operation and was still passing Nos. 29 to 32 French weekly. There was no chill or elevation of temperature in this case after the operation.

Case 22: Deep Stricture with Retention; Retrograde Catheterization. Patient 40 years of age, commercial traveler, with a history of repeated attacks of gonorrhea. He had within two weeks experienced several attacks of retention. When I was called I at first succeeded in passing a fine catheter and relieving the retention. Within twenty-four hours, however, the obstruction increased to such an extent that I found it impossible to introduce an instrument. As the patient objected to perineal section, I aspirated several times in the hope of re-

lieving the retention, and after a time treating the case by dilatation. At the end of forty-eight hours, finding my efforts unsuccessful, I suggested an operation, which was consented to. I found it impossible to introduce a guide, even under an anesthetic. The meatus was markedly constricted. There were several strictures in the anterior urethra. On opening the urethra and perineum I found the urethra was tortuous, and so markedly impinged upon by both old and recent exudate, that after a prolonged search of the urethra I deemed it advisable to perform retrograde catheterization through the suprapubic opening. This was quickly performed, the guide passed from above. On cutting down upon the point of the guide in the perineum, I was enabled to open the urethra posterior to the stricture with great facility, and followed my usual custom of free division of all constricting bands, dividing the roof of the urethra with especial freedom. The anterior urethra was freed from contraction with a dilating urethrotome. Through and through drainage from supra-pubic opening to perineum was instituted, and strands of gauze drawn from the meatus to the perineal wound, through which they were allowed to emerge. On the fifth day the tube was removed, and the case subsequently treated by the systematic introduction of sounds. At the end of three weeks both supra-pubic and perineal wounds were closed. Patient was dismissed from my immediate care at the end of the fourth week. There was a slight rise of temperature in this case, which, however, had not at any time exceeded 100 F. I have not seen this case subsequently, but the patient writes me that he has not been compelled to consult a surgeon since, as he is enabled to pass a 30 French into the bladder with the greatest ease.

Case 23: Deep Stricture with Fistulae and Sinuses. Man, about 43 years of age, stock clerk by occupation, giving a history of numerous attacks of gonorrhea, the last one of which occurred about six months before consulting me. During the last attack he had used very strong injections and he thought with deleterious effects. He stated that he had had for some years, exactly how long he did not know, more or less obstruction to urination. On several occasions he had had attacks of retention from what was termed by several physicians spasmodic stricture. These attacks of retention yielded readily to opiates and hot baths, which according to his story, had been very judiciously used. During the course of his last gonorrhea he had had no distinct attacks of retention, but there had been a progressive diminution in the size of the stream of urine. There is no history of trauma. Some three months before I saw the case a small abscess had formed in the perineum, which had been opened with resulting urinary fistula. Several other small abscesses had formed in the neighborhood at first, so that when I saw the case the perineum was pretty well riddled with sinuses and fistulae, through some of which the urine escaped in considerable quantity during micturition. The patient's general health had remained excellent. On exploration I succeeded in introducing a filiform bougie into the bladder, and within three weeks I succeeded in dilating the stricture up to No. 35 French. The stricture now became resilient and irritable, and all efforts at further dilatation produced well-marked chill and fever. In view of the behavior of the stricture under manipulation and the presence of the fistulae in the perineum, it seemed advisable to perform perineal section. My suggestion to this effect was accepted. The operation presented no special features of interest. There was no difficulty in introducing a small guide on which the stricture was freely divided. All sinuses and fistulae in the perineum were thoroughly laid open. Several strictures in the penile urethra were freely divided, the caliber of the urethra being restored to 40 French, a size which the canal readily admitted after the urethrotomy. Perineal drainage was instituted for four or five days, at the end of which time the perineal tube was removed and the patient allowed to pass the urine through the wound. There was at no time any elevation of temperature. On the fifth day sounds were introduced, this being repeated every three or four days thereafter until the end of the third week, after which time they were introduced once every fifth day. The perineal wounds were soundly healed at the end of the fourth week. I saw this patient a short time since and found the urethra a little smooth and free from contractions, there being no difficulty experienced in introducing a 35 French.

Case 24: Traumatic Rupture of Urethra: Extravasation of Urine.—A boy, 14 years of age, while climbing a fence slipped and fell a distance of five feet, striking astride an iron railing. He sustained a severe contusion of the perineum, and at the same time an injury of one testicle. There was a moderate amount of shock at the time and the lad stated he vomited shortly after the injury. In about half an hour, the pain having passed off, he rejoined his playmates. A short time there-

after he experienced an intense desire to urinate, and while straining to perform the act he felt something give way in the perineum, and there was at the same time a moderate escape of blood which, from the history, was probably mingled with more or less fluid from the meatus. A neighboring physician was called who, after numerous unsuccessful attempts to catheterize, relinquished the case, suggesting that a surgeon be called. I saw the case about eight hours after the injury and found the patient comfortable, he having received a hypodermic of morphia a short time before. The perineum was greatly swollen and ecchymosed, the scrotum being involved in the infiltration. I made no attempt to catheterize, but passed a medium-sized sound down to the penile portion of the urethra and performed perineal section upon it. I found the urethra extensively lacerated and the proximal end of the divided urethral tube with considerable difficulty. I endeavored as far as possible to unite the lacerated portion of the urethra with fine catgut sutures. A hard rubber drainage tube was inserted into the bladder, the wound being packed about it in such a manner as to facilitate free drainage. The scrotum and perineal tissues were freely divided by multiple incisions, permitting the escape of the extravasated urine. The usual antiseptic dressings were applied. Considering the extent and nature of the injury in this case, it was rather remarkable that there was no elevation of temperature following the operation. The favorable course of the case was uninterrupted. At the end of four weeks the patient was up and about. At the present time, one year after the operation, the patient's urethra admits a No. 30 French with perfect ease, and there appears to be no tendency to contraction at the present time.

Case 25: Deep Organic Stricture: False Passages; Perineal Fistula Closed by Plastic Operation.—Man, 45 years of age, with a history of repeated attacks of gonorrhea. Had been troubled with organic stricture since the age of 30. This was dilated from time to time and gave no trouble until he was about 40 years of age, when an attack of retention came on. This was relieved by the catheter and the stricture treated for a short time. He again relapsed into the customary negligence of his case and was practically untreated for several months, when recurrence of the retention occurred. He stated that he had had seven or eight attacks of retention at various times. On several occasions it was found impossible to introduce an instrument into the bladder; the condition subsequently became spontaneously relieved. On at least two occasions the patient stated that false passages had been made, an assertion that was verified by the conditions which I found on examination. It has rarely been my fortune to see such a case with such extensive and tortuous strictures as was present in this man. The meatus had been greatly deformed by a phagadenic chancre with resulting meatal stricture. Beginning about an inch from the meatus the canal might be said to be completely strictured clear to the musculo-membranous junction. Careful examination revealed at least two false passages, one of which opened into the penile urethra and the other at about the perineo-scrotal angle. As the urine had been dribbling away as a consequence of overflow for several weeks, a radical operation seemed urgently necessary. Perineal section was performed without a guide. The perineal portion of the urethra was found to be the seat of an extensive stricture involving its whole length. So extensive was the induration that the urethra was, as the patient expressed it, "very much like a gas pipe," as felt through the perineum. After opening the perineum, I attempted to pass a filiform guide from the meatus to the perineal wound, but found it impossible to do so. By retrograde catheterization, however, I finally succeeded in passing an instrument through the entire penile urethra. A strand of fine silk ligature was tied tightly to the perineal end of the filiform and drawn through the penile urethra from behind forward. A larger and stronger ligature was now fixed to the first and pulled through in the same manner. By a sawing motion—an imitation of Abbe's saw method—the canal was soon freed sufficient to enable a bougie No. 8 French to be drawn through. Increasing sizes of bougies were now introduced until the urethrotome could be passed easily, and the entire length of the urethra was divided upon its roof. The meatus was at the same time freely incised. The canal was thus restored to a caliber of 35 French. My usual perineal drainage and iodoform tamponade were applied. The patient did very nicely until the fifth day, when an abscess formed in the scrotum. The incision had been necessarily made pretty well forward, thus facilitating infection from the operative field, which was necessarily septic, in spite of efforts to obtain asepsis. On further examination I found that the false passage, already alluded to as opening anteriorly into the penile urethra, opened posteriorly into the scrotal tissues. The subsequent

course of the case was very annoying. Numerous operations on tissues of the scrotum were necessary to obtain free drainage. The posterior portion of the perineal wound healed very kindly, but in spite of all efforts to bring about repair, a fistula resulted in the anterior angle of the wound. After about five months' futile efforts to obtain union, the suppurative condition of the scrotum having meanwhile resolved itself into a single sinus at the site of the old false passage, I performed a modified Szymanowski operation on the fistula with, I am pleased to say, the most gratifying results. The patient is now—at the end of two years—able to pass a 28 French with comparative ease, and is in better health than he has been for years.

Case 26: Impermeable Deep Stricture: Retention with Overflow; Combined Supra-pubic and Perineal Section: Through and Through Drainage.—Man, 35 years of age, was referred to me by Dr. Liddy of this city, suffering from retention of urine of several days' duration. Overflow had occurred. The patient was in very bad condition, having been but a few weeks convalescent from a severe attack of pneumonia. There was a history of gonorrhea some eight or ten years previously. The urinary obstructions dated back several years and had been treated with greater or less persistency at spasmodic intervals. On examination I found the bladder so markedly distended that it was almost on a level with the umbilicus. The escaping urine was strongly ammoniacal. The patient had a temperature of 101 degrees and was greatly prostrated. After an hour's careful endeavor to enter the bladder without success supra-pubic aspiration was resorted to and over a pint of ammoniac urine withdrawn. Perineal urethrotomy was proposed and consented to, but at the time of the examination it was nearly dark, consequently operation was postponed until the next day. The patient was seen the following day and immediate operation was declined, with the understanding that it should be performed the following morning in case a second aspiration failed to give permanent relief. I sent the patient to the hospital with instructions to prepare for the operation. The operation proved one of the most tedious that I had met with in my experience. No guide could be introduced. The stricture was extremely tortuous and the perineum extensively infiltrated and indurated. After an hour's fruitless search, during which considerable hemorrhage was encountered, the patient began to act badly under the anesthetic, and I followed the plan which I believed to be best in such cases, and opened the bladder supra-pubically. Retrograde catheterization enabled me to secure a perineal guide, when I found that I had just missed cutting through the stricture into the proximal side of the urethra. The subsequent steps of the operation were quite simple; several slight contractions of the penile urethra were divided and the urethra restored to a caliber of 40 French. Through and through drainage was temporarily instituted. Infection of the cavity of Retzius with considerable subsequent sloughing occurred. There was a succession of slight chills, temperature rising at times as high as 102 degrees F. for several days. At the end of this time the sloughs began to clear away from the supra-pubic wound and the patient's general condition rapidly improved. At the end of about five days perineal drain was removed, and it was found that incontinence of urine existed. This lasted for about two weeks. At the end of three weeks, however, the supra-pubic opening had entirely closed. The perineal wound was practically healed and the patient had regained control over the bladder. He was last seen six weeks after the operation, at which time he expressed himself as being in better health than he had been for fifteen years, and stated that for the first time in many years he was enabled to do his work in a satisfactory manner. The subsequent history of this case is quite sad. Some four weeks after leaving the hospital the patient, who was employed upon a railroad, was caught between two freight cars and instantly killed.

Case 27: Perineal Stricture of Gonorrheal origin with Perineal Fistula from Previous Operation. Man, 38 years of age; occupation, dry goods merchant; suffered from numerous attacks of gonorrhea, first occurring about the age of 20. Ten years later stricture developed. This was followed by successive attacks of retention of urine, which were relieved by catheterization. An attack of retention finally came on, for the relief of which an attempt was made to pass a catheter, but without success. The practitioner in charge of the case did an emergency operation on the perineum and succeeded in relieving the retention, but apparently did not incise the infiltrated tissues in and about the strictured portion of the canal sufficiently freely. Patient stated that at no time subsequent to the operation was it possible to pass a sound larger than a No. 15 French. The perineal wound remained open and a permanent fistula formed as a consequence, in all probability of the

lack of thoroughness of the original operation. The penile urethra was extensively strictured. Three distinct points of well-marked contractions existed, it being impossible to pass a bougie larger than a No. 10 French. The patient consulted me for the relief of the fistula, supposing that his strictures had been cured by the previous operation. I divided the strictures in this case to No. 35 French, a sound of this size being readily admitted into the bladder. The case progressed nicely, excepting that there was a perineal fistula which absolutely refused to heal, the opening corresponding with that of the original fistula. I secured union in this case in a very simple manner by cauterizing the fistulous tract with equal parts of tincture of iodine and carbolic acid, after which two strands of silkworm catgut were passed in such a manner as to include the fistulous tract well down to the urethra, just external to the mucous membrane of the canal. These sutures were shot and although no retained catheter was used the fistula at the end of two weeks was soundly healed.

This patient was last seen six months after the operation, at which time a 32 French could be readily admitted into the bladder. The patient was entirely free from any symptoms referable to the genito-urinary tract.

Case 28: Multiple, Penile and Perineal Stricture; Chronic Cystitis and Retention with Overflow.—Man, 21 years of age, had an attack of gonorrhea at the age of 17, from which he had never recovered, the gleet having been continuous since the original infection. Symptoms of urinary obstruction had existed about a year. Chronic cystitis and follicular prostatitis had resulted from deep infection. At time I first saw the patient retention with overflow had existed some days. The patient was very much run down, with a moderate amount of urinary fever, temperature rising to 101 in the evening. Recurrent chills occurred every few days, followed by the usual fever and sweating. Temperature in the morning was normal, but the greater part of the time there was more or less fever, there being an exacerbation following the chill. Although the condition of the patient was by no means promising, perineal section was proposed. I deferred the operation, however, for twenty-four hours, at the end of which time I gave the oil of eucalyptus in 10-drop doses every three hours with, it appeared to me, a distinct effect upon the temperature. I found it possible to introduce a filiform guide into the bladder. The meatus and several penile strictures were divided; on account of the condition of the bladder prolonged drainage was instituted, a hard rubber drainage tube being used for two weeks after the operation. The patient bore the operation very well, and contrary to what might have been expected did not develop chill at any time thereafter. The evening temperature, however, remained at 101 F. for perhaps four or five days and gradually fell, at the end of ten days being perfectly normal. The urine gradually became clear under alternate treatments of iodoform emulsion and nitrate of silver solution.

I have not heard from this patient since a few weeks after he was dismissed from my immediate care. At that time, however, he was still in excellent condition, was regaining his weight and strength very rapidly, and was a thorough convert to the efficacy of perineal urethrotomy.

Case 29: Recent Traumatic Stricture of the Urethra with Extravasation. Man, 35 years of age, laborer by occupation, received a severe kick upon the perineum during a drunken brawl. Retention came on within a few hours, and according to the history there was evidently at that time considerable extravasation with a good deal of ecchymosis and swelling of the scrotum and perineum. The physician who was called succeeded in introducing a catheter and relieved the tension, catheterization being repeated several times for a week, at which time the patient could pass his urine without assistance, regarding himself entirely well. The physician omitted to apprise him of the necessity of subsequent dilatation of the urethra, so the patient neglected himself and about six weeks after the original injury he noticed that the flow of urine during micturition was beginning to become obstructive. This obstruction rapidly increased until finally an attack of retention came on which the physician was unable to relieve. At the end of thirty-six hours he consulted me, and I found that I could not introduce an instrument into the bladder even under an anesthetic, the stricture being recent and a traumatic one. The condition of the genito-urinary organs being therefore inferentially good, I proposed perineal section. I found that the urethra was completely closed with a fairly well organized exudate, which extensively involved the perineal portion of the urethra. The cord-like band of cicatricial tissue in the center of the perineal urethra appeared to indicate the site of the laceration of the perineal deviation of the urethral walls. The anterior urethra was perfectly normal. The stricture in this case was divided to a caliber of No. 32 French.

which was approximately the normal caliber of the canal. The patient was under my observation for about eight weeks, at the end of which time the urethra admitted a No. 30 sound with perfect ease. The perineal wound was soundly healed at the end of the tenth day. I have had no further information in regard to this case.

Case 30: Linear Stricture of Large Caliber: Fatal Hematuria, probably of Malarial Origin.—A man 40 years of age, a commercial traveler by occupation, consulted me regarding follicular prostatitis and vesical irritation of many years standing, which had followed an old-time gonorrhea. There was also a history of traumatism of the deep urethra experienced during boyhood. The patient had had syphilis and was suffering from chronic malarial poisoning, he having had from time to time quite severe chills, followed by the usual phenomena of ague. Examination showed an extremely irritable urethra, with a stricture in the bulbo-membranous junction. This was irritable, resilient and elastic and admitted a 26 French, but with considerable difficulty and pain. There was a moderate amount of vesical infection; there was no history of hematuria. The patient was extremely neurasthenic. This case had been treated by dilatation from time to time for a period of years, and inasmuch as I believe gradual dilatation to be ineffectual in cases of this kind, I suggested urethrotomy. According to my usual custom I counseled against internal incision of the stricture, believing as I do that in such deep contractions external section is by far the safer. The operation was consented to and duly performed. There were no special features worthy of mention in connection with the operation. The amount of hemorrhage was trifling; the extent of the incision in the perineum and urethra much less than in the usual perineal urethrotomy. There was slight oozing of blood for the first twenty-four hours, and a moderate amount of hematuria from reflux of blood from the tube back into the bladder. This disappeared in several days; the urine was clear; the dressings were changed on the third day and the tube removed, after which time the urine was passed via the ordinary wound. Sounds were passed up to the size of 35 French without provoking hemorrhage, at which time the patient was passing urine quite comfortably through the normal channel. The patient was attacked by a congestive chill, followed by a temperature of 106, with the usual typical sweat; there was at the same time considerable vesical tenesmus; the urine became very scanty and high colored, and within a few hours contained a small amount of blood. Under appropriate treatment the patient became very comfortable by the next day, the temperature within thirty-six hours subsiding to normal. The hematuria, however, continued to a slight extent. At the time the chill came on the patient had a severe nose bleed, and within a few hours several attacks of vomiting, during which blood was vomited. The patient appeared very much alarmed about his condition and seemed to be of the opinion that a fatal issue was impending. I laughed at his fears, as indeed I felt myself justified in doing, as the death of the patient was farthest from my thoughts. On the evening of the tenth day the patient was suddenly taken with vesical tenesmus, apparently due to an accumulation of fresh clots in the bladder. These clots were extruded with such force as to tear open the perineal wound, and following the clots came a profuse discharge of urine and blood. The bladder was frequently evacuated, but was rapidly refilled. Within the space of half an hour the patient had lost an enormous quantity of blood and became almost exsanguinated. I was sent for, but the hemorrhage had apparently stopped, the bladder being evidently filled with clots. I put the patient under the influence of opium and remained with him during the night with the understanding that if necessary a suprapubic section with tamponing of the bladder should be performed in daylight. The patient passed the night quite comfortably. There being no attempt at micturition, there was no hemorrhage. When he awoke in the morning a straining effort at micturition came on, a catheter was passed, with the result that a free hemorrhage with expulsion of large clots began. I immediately opened the perineal wound and tamponed it tightly, then placed the patient on the table and performed suprapubic section. I found the bladder full of clots. The patient acted so badly under chloroform that I found it impossible to ascertain the precise source of the hemorrhage, and so hurriedly tamponaded the bladder and returned the patient to bed. There was profound shock, and the shock in combination with the immense loss of blood he had sustained proved fatal in about three hours after the operation. Transfusion with saline solution and hot rectal enemata containing stimulants, with hypodermic injections of digitalis and strychnia failed to bring about reaction. No autopsy was permitted, which is unfortunately too often the case in private practice.

In reviewing this case I am confident that the hemorrhage was due to causes only indirectly connected with the operation. In this, I think, the reader will agree, when we take into consideration the fact that the course of the case was that of the ordinary successful perineal section up to the time of the development of the congestive chill above described.

Case 31: Irritable Deep Stricture: Repeated Operations.—Man, 45 years of age, referred to me by Dr. F. C. E. Mattison, of this city. There was a history of urinary obstruction of some years duration. This had increased to such an extent that there appeared to be urgent necessity for operative interference. A continuance of attempts at dilatation was advised, but as it subsequently transpired without success. As the patient understood clearly that perineal section would be necessary in case dilatation failed, this was subsequently performed. Through the courtesy of Dr. Mattison I was called to see the case some weeks later, and found that recontraction had occurred. Dr. Mattison turned the case over to me at this time for reoperation. I divided the perineal stricture, at the same time operating upon several penile contractions which in part explained the obstruction to the passage of sounds after the perineal operation. A 35 French was readily introduced into the bladder after thorough division of the contracted points. Subsequent introduction of the sound required considerable manipulation, but could be accomplished with a moderate degree of success. The final result seemed to be very satisfactory, and the patient resumed his business trips upon the road. At the end of about three months, during which time the sound was passed again at intervals, the patient reported to me with an attack of acute retention of urine. There seemed to be very little difficulty in the introduction of the sound, and it was impossible for the patient to voluntarily evacuate the bladder. This condition continued with occasional periods of improvement for several weeks, during which time the patient took a trip to West Baden Springs at the suggestion of some of his friends. He finally returned without any perceptible improvement. I suggested reopening the perineal wound; the operation was performed and the urethra enlarged to a caliber of 40 French. It was found that the penile urethra still retained its patency, and although at the previous operation it had been incised and dilated only up to a caliber of 35 French, as indicated by the register of the urethrotome, at the final operation it was found to admit 40 French without any difficulty. The patient is now, some six months after the last operation, doing nicely. There has been a slight recontraction recently on account of his omission to have a sound passed for nearly two months. A No. 35 French can be introduced into the bladder at the present time, and without doubt a 40 can be introduced within a few weeks.

Case 32: Deep Stricture, Retention and Extravasation.—A man, 30 years of age, mechanic by occupation. Successive attacks of gonorrhea had been experienced, the last occurring one year before consulting me, and the first at about the age of 18. Stricture of the deep urethra developed at about the age of 25. Numerous attacks of retention had occurred and had been relieved with increasing difficulty. Two days before I saw him retention had come on, and while straining violently to urinate he felt something give way in the perineum, after which he said he felt better for a time. On examination I was unable to get a guide into the bladder. The scrotum and perineum were brawny, discolored and infiltrated. Septic cellulitis was evidently impending. The temperature was 101.5 Fahr., and the pulse 120. The general condition was fairly good. Perineal section without a guide was at once performed and free incisions made into all swollen points. Several penile strictures of moderate caliber were left for future attention. Free drainage by iodoform gauze and perineo-vesical tube was provided for. The operation was well borne and the subsequent course of the case unexceptionable. There was some sloughing of the perineo-scrotal tissues, but the application of charcoal and iodoform poultices soon brought about a healthy condition. Three weeks later the penile urethra was restored to a caliber of 35 French. At the present time, two years after the operation, the patient easily passes a 31 French upon himself at long intervals.

(To be continued.)

Small, Troublesome Tumor in Throat. At the last meeting of the Berlin Medical Society a tumor about the size of a pea was shown that had been removed with the tonsil on which it had been growing, mounted on a flexible stem. The patient had been unaware of its growth, but every little while she would choke, cough and exclaim that something had flown into her throat, as the tumor was drawn in with her breath.

SOCIETY PROCEEDINGS

Chicago Academy of Medicine.

Regular meeting held at the Union League Club, Feb. 14, 1896.

Dr. A. H. FERGUSON was chosen chairman.

Dr. B. M. RICKETTS, of Cincinnati, read a paper (by invitation) entitled

A NEW OPERATION FOR RECTAL PROLAPSE AND HEMORRHOIDS.

The great frequency and unsatisfactory treatment of rectal prolapse and hemorrhoids had prompted him to devise means more simple and radical than had yet been employed. Hemorrhoids, both internal and external, together with the two combined, can alike be cured by a submucous ligature applied with a semicircular needle. The pile is first returned and full division made. Only a portion of the varices are caught with the ligature which may be either silk, silk-worm gut, catgut, kangaroo tendon, or silver with the ends protruding at the point of entrance which should also be the point of exit. Any size or number may be ligated without much pain, no hemorrhage, sloughing, or infection. Prolapse in either of the three degrees may be entirely relieved by the same process, while there is a question as to the fourth degree. It may be necessary to make the operation in two or possibly three sittings.

DISCUSSION.

Dr. WM. CUTHBERTSON I have listened with a great deal of interest to the paper read by Dr. Ricketts. Those of us who have had experience in surgery know that hemorrhoids are of common occurrence, and the method which Dr. Ricketts has devised of obliterating the varices is an ingenious one. But I fail to see where the operation can be applied to all cases. I further fail to see how it is an advantage over the common method of applying the ligature. Dr. Ricketts says he objects to the use of the ligature in the treatment of hemorrhoids because it causes too much pain. My experience with the ligature has been that where the mucous membrane has been entirely cut around the hemorrhoid and the ligature applied in the groove made by the incision, there is little or no pain connected with it. He further objects to the ligature on account of the length of time which it takes for the pile to slough off. Where the pile is amputated within a reasonable distance of the ligature, it does not require any longer time for the pile to slough off and heal than it would with Dr. Ricketts' plan. Furthermore, Dr. Ricketts says that his method causes little or no sloughing. Where the plan is used indiscriminately in all classes of hemorrhoids, I should think the cutting off of the circulation in the varices would be as liable to cause sloughing and consequently to cause stricture eventually as by the use of the ligature. I do not think the ligature is applicable to all cases of hemorrhoids; nor do I think the clamp and cautery are applicable to all cases. My plan has been, where the hemorrhoids have been extensive, to use the ligature, particularly where the hemorrhoids have surrounded the bowel. In the smaller hemorrhoids I would advocate the use of clamp and cautery.

Dr. Ricketts condemns the method of injection of hemorrhoids as unscientific and unsurgical. Probably it is. Nevertheless I have injected a large number of cases of hemorrhoids with a mixture of carbolic acid and glycerin, and I have not had any greater proportion of sloughing by the use of these injections than I have by the use of any other means in curing hemorrhoids. I certainly have obliterated varices. Of course, I do not resort to these injections in large hemorrhoids. But in the small, painful, internal hemorrhoids I have used injections of carbolic acid and glycerin with gratifying success. While this method of treating hemorrhoids is discarded by Kelsey and many other rectal surgeons, yet I think there is virtue in it.

Dr. H. K. ADAMSON, of Maysville, Ky. I have listened with pleasure to the remarks of Dr. Ricketts on a new operation for hemorrhoids, although I do not see any special advantage in it over the use of the ligature in the treatment of them. I shall be glad to see the results from time to time of Dr. Ricketts' work, and when he gets his instruments completed I shall use them. In regard to the remarks of the gentleman who preceded me, and who believes in the injection treatment of hemorrhoids, I think if the doctor keeps up this treatment he will have more or less trouble. There is danger of the formation of abscesses by resorting to the injection of hemorrhoids with carbolic acid and glycerin. The danger attending it is too great when we can accomplish the same results more easily with other methods.

Dr. E. H. DORLAND I am exceedingly pleased to be here to night to meet Dr. Ricketts and to have heard his paper. I have read of the submucous ligation of hemorrhoids, but I have

not tried it. I can corroborate the statements made by Dr. Cuthbertson in reference to the injection of hemorrhoidal tumors by a suitable styptic. I have used 10, 20, and even 50 per cent. solutions of pure melted crystals of carbolic acid with the finest salad oil, which is better perhaps than ordinary olive oil, and I have had very satisfactory results. But for several years I have used a prescription that Dr. Foster (as I remember the name) from Texas sent me. He wrote me making some inquiries in reference to a series of articles I published a little while ago in a Philadelphia paper. He gave me a prescription for a styptic, and I like it very much better than carbolic acid, and I undertake to say that I can furnish 500 cases that have been treated from one to ten years that have remained permanently cured of hemorrhoids that were treated solely by the injection method. I am surprised to hear Dr. Ricketts say that he had never used the injection method and condemns it on general principles as "unscientific and unsurgical." Dr. Andrews has done the same thing, but he does not pretend to have treated any cases by this method. He also says it is unscientific and will not treat a case by injection. He looks upon it as a dangerous thing. The opponents of the injection method say that abscesses are formed by it, but if the pile tumor is properly injected with a solution composed of 3 grains to the drachm of salicylic acid, 3 grains to the drachm of boric acid, and 3 grains to the drachm of carbolic acid, and those three heated together into a pure solution of glycerin, and you inject all the way from 5 to 60 drops into the hemorrhoidal tumor; if it has been "scientifically" done, it will not make a slough, and it will obliterate the tumor. I can demonstrate that in five or six cases which are at the Lakeside hospital now. I do not use the injection method where I have an opportunity to treat the case and can keep the patient two or three weeks in bed. I do not use the ligature in the manner of which the doctor speaks; I do not put the ligature around the hemorrhoid at all. I do not use the clamp and cautery, but I dilate the sphincter muscle and cut the pile tumor off. I have yet to see a fatal case from hemorrhage treated in this way. This is to be done under favorable circumstances, and about one-sixth of the pile tumor cut off with a pair of scissors will obliterate the pile. You do not need to go away down into it. By putting in a silk plug filled with absorbent cotton inside of the sphincters, with a cord or double thread attached to it, pulling one thread out upon the perineal side and the other above, and into the bifurcation of these cords pack a few pieces of sterilized gauze across the rectum, place a small roll of gauze and tie the two cords together over this roll of gauze, and it will control any hemorrhage within the pile-bearing part of the rectum. Of course, if you should go deep enough to cut one of the larger vessels it may become necessary to take it up at the time of the operation, otherwise it does not need to be done and the hemorrhage will not be serious. I have not been required to redress a case but twice in three years from hemorrhage, and I have operated on a large number of cases. The difficulty attending the more complicated operations is that they are not practical for the general practitioner with ordinary facilities to treat hemorrhoids. The injection of pile tumors with a styptic, injecting one pile at a time and allowing the man to go about his daily business and curing everyone of the pile tumors, is an established fact, and that beats any surgical operation that has been devised, because patients will be treated in this way if you do not detain them from their business. This is the very best thing that can be done in my estimation. A great many practitioners make the unfortunate statement that they have never tried the injection method because it is unscientific. Isn't anything in the practice of medicine scientific that will cure a case easily? We do not have to say in our school of medicine that we use the ten-millionth of a drop of something to cure a certain case, but we give a ten-millionth or even a teaspoonful, if we think it is necessary. Either one is scientific. I deprecate the use of the word unscientific in the treatment of pile tumors by the injection method.

The clamp and cautery to my mind is as barbarous an operation as one can make on a human being. A man ought to be prosecuted for using the clamp and cautery to cure piles; it is a perfect terror in this day, considering that the method of injecting these tumors with a styptic is far superior to the use of the clamp and cautery. With Dr. Cuthbertson, I fail to see wherein a ligature put around under the mucous lining, drawn tight and tied, will cause much less pain than when put on the outside of the mucous membrane and tied tight. The nerves are not all involved in the mucous membrane of the rectum. It occurs to me that this method, which has been outlined by Dr. Ricketts, is intended to be so difficult that but few of us can use it.

I am very much interested in the male and female needles of which the doctor speaks, and I want to see how they are going

to work in connection with operations for the removal of hemorrhoids. I have never seen an external pile tumor in my life but what could be the easiest treated, for the patient and surgeon, to take a sharp instrument, cut it right open, and let the clot out. There is nothing more to do with it. Slit an external hemorrhoidal tumor down, dress the case, and let the patient go, whether the tumor is as large as a hazel nut or a small hen's egg. It occurs to me it is unscientific to ligate an external pile tumor, equally so to inject it. The gentleman from Kentucky speaks of abscesses being formed. In not a single instance have I had an abscess formed where the pile tumor only has been injected with the styptic. If you keep the needle well into the pile tumor from the base and carry it up to and not out of the apex, draw it back and inject clear down to the point of exit, as you withdraw the needle, you will seal up the pile tumor and not a single drop of blood will escape, and you will never have the formation of an abscess.

DR. W. A. PALMER, of Evanston—I must protest against the censure of the last speaker upon the clamp and cautery method. My experience has not been as extensive perhaps as some others, but the cases in which I have used this method have been attended with brilliant results. I fail to see how it is more painful for an internal pile, as the patient must have an anesthetic during the operation. After the operation has been performed and the rectum properly packed, the patient given small doses of morphin or opium powder, he can be made quite comfortable. This method has worked beautifully in two cases. With regard to prolapse, I have had no experience whatever.

DR. A. H. FERGUSON—I am very pleased to have been present to hear the remarks of Dr. Ricketts in the presentation of his new operation for the cure of hemorrhoids. The production of any operation for pathologic conditions, in order to be ideal, it must remove those conditions with the greatest safety to the local tissues and to the patient, that is, to secure union by first intention without sepsis. The remark has been made that asepticity in the rectum can not be positively secured, and that it should not be attempted. I must say, that we can in a number of operations in the rectum secure union by first intention. By taking all antiseptic precautions we can prevent the local septic infection in the majority of cases. It is true that asepticity is only a comparative thing on the skin in any part of the body; the resistant power of the tissues overcomes a minimum amount of sepsis in the rectal tissues, and we frequently get union by first intention.

The ideal operation to me for the cure of hemorrhoids is to amputate the hemorrhoid as you would a diseased finger, to tie the vessels by themselves and to sew the mucous membrane over it, and then put the sphincters at rest, with a rectal tube well protected with iodoform gauze. In at least 75 per cent. of the cases treated in this way I have secured union by first intention. In doing this we should use such material as will be absorbed, and that is aseptic catgut. I regard it as the ideal material of all buried sutures. The pathologic conditions in hemorrhoids are varied, and I do not believe we can lay down any single operation that will meet them. For instance, we have an external pile and an internal one. The treatment that is suitable for an external pile is not always suitable for an internal one. The treatment that is suitable for the strawberry or capillary internal hemorrhoid is not suitable for a hemorrhoid in which arterial supply predominates, or a hemorrhoid that may predominate with venous dilatation. When there is a simple hyperemia or slight dilatation with very little or no pathologic condition in the region of the rectum, many cures can be effected by dilatation alone. The method brought forward by Teale years of dilatation of the rectum and emptying the vessels, putting the sphincter at rest so that the circulation returns, when there is no pathologic condition within the dilated piles, has been the means of effecting cures in a number of cases. That treatment might have been supplemented with massage, and patients need be detained but a short time from their work. In certain cases the injection treatment is admirable, particularly in that form of pile which is principally composed of capillaries, where the method can be used safely and successfully. But the form of pile which has large arteries running through it is not so suitable for the injection treatment; nor is it suitable in those cases where the veins are considerably dilated, having large cavities or lacunae on the inside, from which the injection material may be absorbed and cause grave constitutional effects. It is in cases of hemorrhoids with extensive pathologic conditions that the injection treatment does the least amount of good. But, as Dr. Dorland has said, it depends a great deal upon the operator, the amount injected, where it is injected in order to avoid large vessels, and if the surgeon can surround the pile tumors so as to constrict them with cicatricial tissue following the injection, then good and

well. But to indiscriminately recommend the injection treatment for all cases of hemorrhoids is not good practice. It has its place, however. The ligation treatment has its place, too. Ligation is very suitable where there is a large artery passing through the pile tissues. I very frequently apply a clamp and cut the pile off, if it is a large one, and if there is a large vessel or vessels coursing through it, I then make a flap of mucous membrane on each side of the clamp, tie the vessels, sew the mucous membrane over it, or else apply a ligature in the usual way. There is the same objection to the application of the silk ligature that there is to the subcutaneous ligature, namely, local infection and secondary hemorrhage which come on after pathologic changes have taken place through the introduction of septic material. The hemorrhage comes on from the sixth to the twelfth day. How does it come on? It comes on by local infection, causing ulceration, the ulceration extending to the white embolism inside of the vein and breaking down that which nature throws out in the vein to close it up, and hemorrhage occurs. The same objections apply more forcibly to the subcutaneous ligature than to the open ligature. When we can go to work and treat with clamp and cautery hemorrhoids of almost every character and get first-class results, then I should say that this method has its place in surgery. It has its peculiar advantages in that it wards off sepsis from the tissues at once, that is, it forms an eschar immediately which is not capable of absorbing for a few days, and by that time nature will have thrown out a wall of granulation tissue, and this granulation tissue is the best fighter nature has against germs. I should say, therefore, that the clamp and cautery are applicable to all cases where the hemorrhoid is mostly composed of veins or capillaries. I do not believe in Whitehead's operation. I would simply say that the evil results which have followed Whitehead's and Pratt's operations have been clearly pointed out by Dr. Andrews of this city and others, and are procedures which may be characterized as very unsurgical, in that they are apt to cause strictures and other subsequent conditions which I need not mention here. I would only do Whitehead's operation in connection with epithelioma of the rectum, where, at the same time, we have hemorrhoids to deal with. Then we have to remove both the pile and cancerous area. I have resorted to Whitehead's operation in such cases with excellent results as compared with other operations for cancer in this locality.

With reference to the crushing operation I am not in favor of it.

Coming now to Dr. Ricketts' subcutaneous ligature for the treatment of hemorrhoids. The history of subcutaneous ligatures in the other parts of the body, in varicose veins of the legs, and in varicocele before the days of asepsis was not very good. After local puncture, which was often through the veins, very frequently asepsis was carried at once to the tunica intima of such veins, finding ready access to the constitution, causing septic phlebitis and death. We find the same history in connection with varicocele that not unfrequently death took place in a similar manner. We may carry subcutaneous ligatures around the veins in the extremities and scrotum and antiseptically seal these punctures up again, but we have better methods now. In inserting a subcutaneous or submucous ligature, what does it do? It passes in, it is true. You do not know but what it is passing through the middle of an enlarged vein; you do not know but that you are tearing through an artery. You bring it out and tie it. What does that do? It constricts the part within the ligature, but it leaves a small hole through which sepsis is bound to take place in the rectal region and the hole is not large enough for efficient drainage. It does more—it shuts off the nutrition to the mucous membrane on its surface. What does that do? It causes gangrene, or sloughing, followed by ulceration, cicatrization and contraction. The silk ligature has to come away by a process of ulceration and, you can not have the latter condition in this locality without local pus formation. You have all the dangers of both local and constitutional infection, one being immediate and the other remote. Following the sloughing there is the danger of stricture.

With regard to prolapse and its treatment by the subcutaneous ligatures there are many objections. I should try to keep it back with the use of astringents, careful regulation of the diet and supportive treatment, restoring the function of the levator and sphincter ani muscles. These muscles are very much relaxed in rectal prolapse. This treatment failing, a good old method is to canterize the mucous membrane in longitudinal strips about half an inch or three-quarters of an inch apart, and then replace the bowel. By doing this we cause inflammation and plastic material is thrown out. The cauterization wards off infection until we get sufficient contraction of the redundant mucous membrane, and we do not run the risk of

infection. The operation is not followed with the same degree of shock that attends any of the cutting operations. That failing, excision has been done with success. But I would not favor it except in tissues that are already sloughing and where we have to resort to it on account of ulceration and sloughing. A treatment of prolapse of the rectum, as brought forward and practiced by Bryant, is to give the rectum complete rest, to perform colostomy, to treat the rectum locally until it is in a proper condition to perform its function again, and then closing the opening in the colon. I see no reason why, in the fourth degree of prolapse where we get invagination, we can not treat it successfully by laparotomy. This may be done with greater safety than operating from below. The upper part of the rectum and the sigmoid should be fastened to the abdominal wall.

DR. CARL BECK. I regret that I did not hear the paper of Dr. Ricketts. Not having heard it, I am at a loss to know what to say in the way of discussion. But with reference to the remarks of Dr. Ferguson as to prolapse of the rectum, I would like to mention a case of very extensive prolapse. The woman has been treated for prolapse by three different (eminent) surgeons in Europe, and each time by a different method. One operator stitched up the prolapsed portion of the rectum into the retrorectal excavation, excision of the lower portion of the rectum was performed by a surgeon from St. Petersburg, whose name I can not recall, and the third operator did a laparotomy. The last operation was performed about a year ago. The prolapse has recurred after every operation. The patient has been under my observation for nearly six months, and the prolapse is now at least eight inches from the orifice. When she stands up it is impossible to retain it by any apparatus. It is a constant source of pain, etc. I shall in a short time try another laparotomy, and I have devised a plan to stitch the flexure all along the abdominal wall as far as it is movable. From the letter I received from the last operator I judge that he only put in three or four sutures in his operation, and that these sutures had given way. As I understand, he has sutured the lax parts of the intestine to the lax parts of the abdominal wall, and the sutures have formed long bands, then giving away and prolapse recurring. Cases of such extensive prolapse as this are extremely rare. In such cases nothing will do good except to firmly unite parts of the muscles or abdominal fasciae with sutures that go deep down. These sutures should be silk that will not be absorbed, and not catgut.

DR. RICKETTS (closing the discussion) I am under obligations to you for the manner in which you have considered my paper. It pleases me very much, but I can assure you that I have never before fallen into the hands of such Philistines. I did not come to Chicago to try to teach you anything. That was not my object, but to tell you what I have been doing. I do not believe the members of the Academy have understood what becomes of the ligatures. The ends of them are allowed to remain exposed, in that way we secure drainage. I do not propose to bury any ligature in this operation, as I think that would be unscientific. I have never resorted to the injection method in the treatment of hemorrhoids, because I have seen and known of several bad results. Quite a number of malpractice suits have been instituted as a result of the injection method. As to the classification of hemorrhoids, I am frank to say that no operation should be resorted to, to the exclusion of others. No one will deny that there are dangers in connection with the injection method, and shall we subject our patients to those dangers? I understand that a surgeon of this city lost a patient a little over a year ago after using the clamp and cautery from hemorrhage, the hemorrhage occurring on the tenth day, and at the end of the twentieth it was fatal, so that we can not deny the fact that the clamp and cautery have their dangers. As to the loss of time in making the operation which I have suggested, if it is done on Saturday afternoon the patient is able to attend to his business on Monday, and so the loss of time is practically nil.

As to infection, it has not taken place in any of the cases. I have operated upon, nor have I heard of its having occurred in cases operated on by others, for the simple reason that the ligature is allowed to remain exposed and to come away *ad libitum*, or to be taken away at the end of ten days after it has served its purpose. It is not necessary to make the ligatures very tight, but the constriction should be sufficient, however, to obliterate the vessels.

As to the injection of external piles, it is in such cases that we usually have abscess, and they are the most dangerous. I have been told that the cases that caused Dr. Brinkerhoff the most trouble were the cases in which the piles were external.

As to the use of the cautery, there are cases now and then where we can use it. There are also cases now and then where we can use the injection method; but where we have so many remedies for a disease we must rest assured that none of them

are satisfactory. So it is with operations. There are many ways of treating hemorrhoids. We are trying to find the best method of dealing with them.

As to the 25 per cent. of failures which Dr. Ferguson speaks of, or rather 75 per cent. of successes in which he says union by first intention is secured, I would say that 25 per cent. is sufficiently large to put us on our guard. It is in these cases that the risk of infection is very great.

As to secondary hemorrhages, I have had none in my experience. There might be danger of such hemorrhage. I am aware that we might puncture an artery or divide it; we catch up part of it and leave the other part out. If we are going to have hemorrhage it is most liable to occur at the time of the operation. In the case reported by Dr. Beck the methods that were resorted to have been unsatisfactory, and it seems to me we must do something more than we have been doing.

There is one matter that has been entirely overlooked, namely, the position of the sigmoid in quadrupeds. It lies parallel to the spine. There are no adhesions; it is perfectly free. When we get up upon our hind parts or stand erect, we find the sigmoid falls down and the intestines above the sigmoid vessels run around it, while in the rectum they run perpendicularly with it. If you examine a case in the dead room you will find the sigmoid falls forward and becomes adherent to the anterior parietes. I have not heard this condition spoken of before. I have found it myself, and I find that anatomists who have given the subject any thought tell me the same. We find from investigation that bipeds are the only animals that have hemorrhoids. Monkeys have hemorrhoids, and, of course, human beings have them, but we do not find them in quadrupeds. The sigmoid of animals is not corrugated like the sigmoid of a human being, a thing that changes the aspect of the pathology and the anatomic relations very materially. As to what we shall do in cases of prolapse, we are as yet undecided, and in the case Dr. Beck speaks of in which three different operations were performed by eminent surgeons, are we not convinced that something more should be done than has been done for these cases? What is it? We can not very well cut down and take out a section of the sigmoid; but if there is any part of the alimentary tract where we ought to be able to do this it is from the sigmoid, because the stenosis is not as great. The lumen should be greater, allowing plenty of room for fecal matter to pass down. I would therefore suggest, as pointed out by Kraske, that we anchor it above or go above and make an abdominal section. So far as I have been able to determine I have not found a patient who has been relieved of prolapse in the fourth degree. I speak of this and throw out the suggestion that we may be able in the future to remedy this defect by the injection of any of the solutions that will enable us to get up adhesions and anchor the part there. Dr. Beck's suggestion might possibly be carried out and this trouble relieved, but I think it would be impracticable for him to suture the descending colon to the abdominal wall. It would have to be done to such a great degree, and if pulled upon itself, now, what will it do if we have the whole cecum with its contents behind it pulling down? Does the remedy for relief lie in the excision of a portion of the sigmoid, say of five or six inches, or as much as necessary, or does it lie in the injection of solutions for the purpose of getting up adhesions?

With reference to the operation that has been suggested of using the cautery in the prolapsed rectum, that it will answer the purpose in the first and perhaps second degrees I have my doubts. If we are to sear the rectum perpendicularly with the cautery and rely upon it as a remedy, it seems to me very unsatisfactory. I understand that Kelsey (I got my information from a student) in cases of prolapse takes the round ball of the Paquelin cautery, red hot, introduces it into the rectum and draws it backward and forward two or three times. I can not conceive of anything more cruel and not in keeping with the principles of surgery than to use a red hot iron in the rectum, expecting stenosis to result from it.

In closing, I would suggest that in the future you go to the dead room and study the condition as we find it in the human being. If you take the dog or the sheep you will not find hemorrhoids, but in monkeys you will find this pathologic condition.

DR. ROSA ENGELMANN read a paper entitled

ANTITOXIN IN ONE HUNDRED CASES OF DIPHTHERIA.

(See the JOURNAL, February 22, page 374.)

DISCUSSION.

DR. WM. L. BALLENGER. I have been especially interested in the facts and figures presented by Dr. Engelmann, one of the important points being the value of the early administration of antitoxin in cases of diphtheria. I read recently some statis-

tics which were very interesting to me, corresponding very well with those given by Dr. Englemann. Out of 1,445 cases under the old method of treatment, there was a death rate of 45 per cent.; 2,740 cases were treated with antitoxin, this number including laryngeal cases and other types of the disease, with a death rate 18.5 per cent. Of the cases in which antitoxin was administered on the first day there were no deaths. Its administration on the second day was followed by a death rate of nearly 3 per cent., on the third day 10 per cent., on the fourth 20 per cent., on the fifth 33 $\frac{1}{3}$ per cent., on the sixth and later days, 41 per cent., showing a gradual increase in the rate of mortality with the lateness of the administration of the antitoxin. Its early administration is exceedingly important, and yet we should not refuse to administer antitoxin even in the later stages of diphtheria. I know of repeated instances in which it has acted with very prompt and gratifying results after four to six days development of the disease.

Dr. Palmer, who is present to-night, had a case of laryngeal stenosis due to diphtheria which I saw in consultation with him only a few days ago. The stenosis had existed for four days, the breathing being quite labored most of the time. Antitoxin was administered and inside of nine hours there was great relief and the child is now perfectly well. In the family there had been a number of cases of diphtheria preceding this one some three or four weeks. Bacteriologic cultures were made and verified in all the cases. The patients were all treated with autitoxin, making good recoveries. In this case there was also a bacteriologic examination made and the true bacillus found. Although we could not get at the membrane to touch it. A culture was made from a specimen secured low down in the throat and showed the existence of the Loeffler bacillus.

There are some points we should remember in treating these cases beside the administration of antitoxin, and which have a great influence upon the recovery of the patient. One of these is the surroundings of the patient. The patient should have plenty of sunlight. The germs grow in dark, damp places, but an abundance of sunlight and fresh air is unfavorable to their development. In one of the great children's hospitals in London during an epidemic of diphtheria, it was the custom to remove the diphtheritic cases to the non-diphtheritic wards two days after the membrane disappeared. In no instance was there an outbreak of the disease in these wards, although there were undoubtedly germs still in the throats of the convalescents. In the meantime an adjoining building was being torn down and such clouds of dust were entering the hospital that the management closed the windows and shutters to keep it out. A few days later a violent epidemic of diphtheria broke out in the wards which had heretofore been exempt. This circumstance indicates very clearly the advantages of fresh air and sunshine in controlling the disease. I understand that Klebs has made some experiments with the toxin of the germ itself, making cultures in some fluid media, then filtering the germs from the fluid leaving the toxin as the remedial agent. This treatment is similar to Koch's tuberculin, and in fifty-one cases which he has treated the death rate was 13 per cent.

If we will remember that every germ manufactures an excrement made from its own environment and for a moment consider ourselves germs, the excretions of our bodies being the manufactured product, we can easily understand how life would be very short under such circumstances. The same thing may be said of germs and their toxins. I understand that Klebs is now using the toxins of the Loeffler bacillus in the treatment of diphtheria and while the serum treatment is probably the best at our command, it will be of great interest to know the results of his experiments. Medicine is upon the threshold of a new era. As the laws of physiologic chemistry, and of pathologic processes become better understood, treatment will be more in harmony with physiologic laws, and toxins and antitoxins will find a larger place as remedial agents.

Dr. Wm. Cuthbertson After being strongly opposed to the use of antitoxin I have become a convert. In some cases of diphtheria which occurred in this city in my practice, when antitoxin was first introduced, my brother and I used it in several cases. Our results were bad. I am inclined now to attribute the bad results at that time to the imperfection of the antitoxin. My reason for being converted to the use of antitoxin was a case I had several months ago of diphtheria in which the membrane extended down to such an extent that there was laryngeal stenosis, and it seemed as if intubation or tracheotomy would have to be done. I made up my mind to try the antitoxin which had been lauded so highly. I therefore injected, on the fourth day, 600 units of the antitoxin, and still kept up local treatment and free stimulation. The laryngeal stenosis was stopped and the child began to breathe freely

on the next day, and eventually recovered. I might say that a microscopic examination was made in this case and the Klebs-Loeffler bacillus found. The next case of diphtheria I had, which was several weeks afterward, and in which the bacillus was also found, showed signs of laryngeal stenosis at the very outset, and having had such good results in the other case from antitoxin, on the second day of the disease I injected 600 units of antitoxin. The laryngeal stenosis did not get worse, but gradually cleared up. The effect of the antitoxin in each of these cases was to produce almost total anuria. The kidneys were acting freely in both cases before I had injected the antitoxin, an immediately after the injection they stopped secreting, or for the first thirty-six hours after injection of the antitoxin there was not more than three or four ounces of urine passed. I made an examination of the urine in each case and found it loaded with albumin. After the application of hot poultices and diuretics the kidneys began to secrete and gradually kept on increasing until the normal amount of urine was voided. Had the cases been placed on a liquid diet from the start the amount of urine might have been normal throughout the disease. Ten days after the injection of the antitoxin an urticarial rash appeared, and the temperature in each case rose to 100.

Dr. Englemann has referred to the part which the staphylococcus might play in this connection. We know that when the staphylococcus comes in contact with a surgical wound gangrene is set up, a slough is formed and gradually thrown off. In a case in which the staphylococcus comes in contact with a lesion of the mucous membrane, either in the larynx or pharynx, I see no reason why it should not act in the same manner in a case of throat trouble as it would in a surgical wound.

Dr. Englemann made further reference to the apparent interchangeability of these germs. Those of us who can look back to the time before the Klebs-Loeffler bacillus was discovered can recall to mind cases of scarlet fever where there had been angina associated with it. The disease would be well marked in one case, and in other members of the family who had been exposed to the contagion we would find trouble set up presenting the clinical picture of true diphtheria. I have seen the same happen in cases of measles where there has been sore throat connected with the measles, and in the other members of the family disease would be set up which would present a true clinical picture of diphtheria.

Dr. PALMER I would ask Dr. Englemann about the febrile reaction.

Dr. ENGELMANN—In some cases I have gotten it, in others I have not. It is the rule to have a rise of temperature after the administration of antitoxin.

Dr. MOYER Have you observed cardiac paralysis following the use of antitoxin?

Dr. ENGELMANN—I have seen cardiac paralysis twenty-four hours after the use of antitoxin in two cases, and whether it was due to the antitoxin or toxemia is a question; and faucial paralysis in one case.

Dr. PATRICK How long after its administration?

Dr. ENGELMANN—About eight or ten days.

Dr. ENGELMANN (closing the discussion)—I would like to speak of the manner in which the membrane sloughs after the use of antitoxin. An absolute necrosis takes place, and if you watch the throat you will see the edges of the membrane curl up, and within twenty-four hours it is extruded *in toto*.

Another question that arises is, Shall all children exposed to diphtheria be immunized? I find there is great objection among practitioners to immunize children not exposed. When it comes to the question of adult immunization I think we can leave it, because adults are not so prone to infection, unless they are in the midst of it all the time, as children are.

Dr. Ballenger has referred to hygienic measures. There is no question but that we should use antiseptics, tonic and stimulant treatment in connection with the use of antitoxin. Baginsky, of Berlin, makes a good argument in that he says we must effect a reduction of the toxin *in loco*, because it is the toxin that is doing the bad work. Therefore, if we reduce the production of toxin we will have to use less antitoxin.

As to the subject of toxin injections, it seems to me that the use of antitoxin is a more reasonable procedure, because in a normal case of diphtheria the blood of the patient itself is trying to manufacture antitoxin. Heretofore, when a patient got well, the antitoxin produced enough vitality to offset the toxin that was formed. Why should we put extra work upon cellular organism by introducing toxins when we can lessen the labor of the organism by using antitoxin?

Dr. Cuthbertson is not the only convert to the use of antitoxin. I find that the greatest number of objectors are those who have never used it and will not use it. Practitioners seem to object to the use of antitoxin upon general principles.

Dr. Cuthbertson reports a case of beginning laryngeal stenosis in which he used 600 units of antitoxin. My experience has taught me that small doses do not always prevent the use of intubation or tracheotomy, and in my later experience I learned to use antitoxin in more heroic doses, thus averting tracheotomies and intubations. Another point I wish to make is this, that the practitioner should not wait for stenosis to manifest itself before using antitoxin. I would ask Dr. Cuthbertson whether he found albumin before or after the administration of antitoxin?

DR. CUTHBERTSON Immediately after its injection.

DR. ENGELMANN The only way to reach a conclusion in reference to this matter is to examine the urine both before and after the administration of antitoxin. In twenty-one cases recently immunized an examination of the urine was made before and afterward, and no albumin was found to be present.

As to the interchangeability of the bacilli, I meant the interchangeability of the pseudo-bacillus with the Klebs-Löffler bacillus.

DR. REILLY Don't you mean by interchangeability that the germs change from virulency to benignancy, or *vice versa*?

DR. ENGELMANN Yes, I tried to convey that idea. It is supposed that the pseudo-bacillus is an attenuated form of germ.

As to the question of rashes, when I began to get out statistics I did not take the opus of each bottle of antitoxin I used. But now I take the opus, the date of manufacture, in order later to possibly trace it to the opus. I think New York men have done some of that work, but I do not know that it has been considered conclusive.

As to administering antitoxin in the late stages of diphtheria, I should not hesitate to use it, although we can not expect so much from it. Still I have seen it used in the late stages when it has done good.

DR. PATRICK Have you noticed any unpleasant effects from the immunizing dose only?

DR. ENGELMANN Yes, in some cases. I have seen the development of a rash due doubtless to the immunizing dose. For instance, a brother and sister received a dose of antitoxin from the same bottle. The brother developed a mild urticaria; the sister an erythematous rash of one extremity, attended with swelling of the knee and a great deal of arthritis. Why in one case the rash was mild, and in the other it produced such a profound impression, I do not know.

DR. PATRICK Have you noticed any cases of cardiac failure?

DR. ENGELMANN One case which occurred since writing my paper, in which I noticed a lighting up of a previous chronic heart trouble, or at least an exaggeration of it. It is the only case I know of.

DR. PATRICK What was the previous heart condition?

DR. ENGELMANN The girl had mitral stenosis, and after the injection of one part of the No. 3 for the diphtheria, she having refused to be immunized, she developed urticaria, muscular pains and a little arthralgia, and about three weeks after the injection of antitoxin complained of heart trouble.

SELECTIONS.

Influence of Lecithin on the Growth of Organisms. Experiments with dogs and other animals show that subcutaneous injections of lecithin increase notably the number of red corpuscles in the blood. They rise to 800,000 or a million and more above the normal, and the hemoglobin is also increased. This improved condition of the blood comes immediately and lasts a long while. The scientists who have made a special study of this subject are Danilewsky, Selenski and Sostin, and their report to the Académie des Sciences is full of interest. Experiments on the egg and larvæ of frogs showed that it produced an extraordinary growth in the tadpoles, and these tadpoles showed much less pigment than the others. Lecithin does not act like a food. It is not an organo-plastic substance. It increases the assimilation of the food, and has a direct stimulating influence of great importance on the processes of multiplication among the cellular elements. The improvement of the blood, we know, is the most important condition to stimulate the growth of the organism, that is, the multiplication of its morphologic elements and their development. And this, lecithin accomplished in these experiments. *Semaine Médicale*, January 8.

Amygdophenin, the new Remedy for Rheumatism.—The effect of this new remedy in acute articular rheumatism has been carefully studied by Stüve (*Centralblatt für klin. Med.*, Nov. 16, 1895), who also observed incidentally its effect on fevers and neuralgia. Amygdophenin (ethylamygdophenin) is a derivative of paramidophenol, in which, in the amid group, an atom of hydrogen has been replaced by the amygdalic acid group, and the atom H of the hydroxyl group, by the carbonate of ethyl. It is a light whitish gray, crystalline powder, hard to dissolve in water. After administering it, a derivative of paramidophenol is found in the urine, the reaction of the indophenol. Stüve administered it in twenty cases of articular rheumatism, eleven of which were attended with fever. In seven cases in this group a notable improvement manifested itself in two days after commencing its use. The local symptoms and fever had disappeared entirely by the end of four to six days. With the exception of one patient, who brought on a relapse by leaving his bed too soon, the cure was permanent in all. One patient had been annoyed by the buzzing in his ears caused by salicylate of soda in former attacks, but when amygdophenin was given him, there were no attendant annoyances, but recovery in less time than ever had been caused by the salicylate of soda. In the other four cases in this group the result of the use of amygdophenin was not the same in all. The effect was not very successful in two cases, one with cardiac trouble, and extremely tardy recovery in another. On the other hand, fine results were obtained in one case where there was serious aortic insufficiency; marked improvement followed the administration of 3 grams of amygdophenin, which cured completely an intercurrent and slightly febrile attack of acute articular rheumatism. The only absolute failure in the use of amygdophenin was in a case of pain in the joint of one knee. But this was probably a blennorrhagic rheumatic trouble, in which all the other antirheumatics have less efficacy. In the four cases of febrile articular rheumatism the amygdophenin produced a complete and rapid cure, with one exception. This was a case of simple pain in the joints without objective phenomena of any kind. In one case the amygdophenin was replaced for a few days by salicylate of soda, which did not have the slightest effect, and not until the amygdophenin was restored did recovery continue to a permanent cure. As an antipyretic it was tried on some phthisic patients with fever. One-half gram had no effect upon the temperature. One gram lowered the temperature 2 degrees C. in one case with profuse perspiration, but in others the same dose only lowered the temperature one-half to one degree C. and not at all in others. It is therefore impossible to count upon amygdophenin as an antipyretic at this dose. In neuralgia it produced good results in several cases, but of course its effect is only palliative. However, it was noted that it acted favorably even in cases where the pain had a central origin, as in tabes, sclerosis, etc. It was administered in one gram doses from one to six times a day, at first in powders and later in compressed tablets. One gram doses never produced any attendant annoyances of any kind in the series of observations noted, amounting to about one thousand in all. In one, the patient after taking 5 grams in twenty-four hours, complained of a slight vertigo; another who had taken 6 grams noticed a buzzing in his ears, but both of these vanished at once when the amount administered daily was reduced. No exanthema was observed in any case, nor dyspeptic troubles, nor renal inflammation. Three cases only had sweats. Stüve sums up the result of all his observations in the announcement that in amygdophenin we have a most valuable remedy for rheumatism, reliable and entirely innocuous. It acts in cases where the other antirheumatics, such as salicylate of soda, produce no effect, or must be discontinued on account of attendant disturbances. As to its use in pyrexia and neuralgia Stüve does not consider the limited number of observations on record as sufficient data upon which to found an official opinion. *Ther. Woch.*, 1895, No. 47.

Infective Inflammation of the Parotid Glands. The *Journal de Méd. de Paris* of Jan. 19, 1896, contains a study of three cases of this kind interesting on account of their etiology and treatment, by Regnier, surgeon at the Lariboisière. He says that until recently we have always considered these parotid inflammations as caused by some secondary inflammation of the lymphatic glands. We are now becoming aware of the fact that it is the glandular pockets of the gland itself that are involved, resulting from a primary inflammation of the excretory canal. The infection starts in the mouth and passes up through the excretory canal to the pockets of the gland.

Chassaignac first called attention to this variety, which he called canalicular, characterized by swelling of the parotid region followed by pus discharging through the duct of Steno. Virchow and Weber also observed cases where the pus and the lesions were in the excretory canals and the alveoli. But Crocq as early as 1873 tried to prove that every case of parotid inflammation with a general cause is preceded by some inflammation in the mouth, which extends into the gland through the duct of Steno. The recent histologic and bacteriologic researches of Claisse and Dupré confirm this view. In a large number of cases they were able to trace directly the upward extension of the infection from the mouth up into the gland. It is in this way we know that infection finds its way into the liver, the kidneys, the bronchial tubes and the breasts, through the excretory ducts and it is the same with the parotid gland, probably. But this opinion must not be regarded as absolutely settled, although it has been verified in a large number of cases. Duplay, in his *Treatise on Pathology*, suggested that the infection might arrive by way of the lymphatic glands, and in that case it is not the parenchyma of the gland but the lymphatic ganglia that are affected. This location of the inflammation must be borne in mind as possible when diagnosing, but if it is of lymphatic origin an abscess will form, the opening of which will show an accumulation of pus. But if the inflammation is in the glandular pockets and is being infected through the excretory duct, the lancet only brings out a few tiny drops of pus, contained in the pockets of the gland, into which it penetrates, while the edema, the swelling, and the sensation of fluctuation, would have made you confident that there was a considerable accumulation of pus there.

It seems as if lancing it had done no good, but in reality it is followed by a fall of temperature and local improvement, and the issue of pus later through the duct of Steno explains the above phenomena, and proves that it is a glandular inflammation with the pus secreted in the acini or excretory canals.

My first case was a woman recovering from typhoid fever, who became very much swollen in the parotid region, with edema, and fluctuation accompanied by fever. Convinced that there was a large collection of pus, I opened straight into the parotid gland, and found to my surprise that scarcely anything issued from the incision, a few tiny drops of pus being distinguished with difficulty in the blood that followed. The temperature decreased however, and a couple of days later I saw pus exuding from the duct of Steno. The swelling diminished and a permanent cure ensued. Another case was a man of 45, large, alcoholic, suffering from multiple articular rheumatism and acne. The parotid region began to swell, there was edema and fluctuation and I opened the abscess as before, using a grooved director and passing through the whole gland, without finding any accumulation of pus. But the temperature fell afterwards, and a couple of days later pressure on the swelling discharged pus through the duct of Steno into the mouth.

A patient came to me suffering from a urinal abscess which I lanced. Convalescing from this he was attacked with erysipelas of the face, for the second time in his life. One injection of Marmorek's antistreptococcus serum was made, and the erysipelas passed away, as it might have done without the injection, perhaps.

An abscess next formed at the spot where the serum had been injected, which I opened and found full of streptococci. A few days later the parotid region began to swell, puffiness and fluctuation ensued and I opened the swelling, out of which poured a large quantity of pus, also full of streptococci. Evidently in this case I had lanced a ganglion abscess, infected through the lymphatic gland.

These three observations show that infection may reach the parotid glands, through the excretory canals or the lymphatic glands producing in one case what Chassaignac calls a canalicular parotid inflammation, or acinous adenitis, and in the other a simple adenitis. In the latter case a certain amount of pus will follow the knife, but in the former case you will not have the satisfaction of seeing the pus escape. But you need not fear that you have made a mistake in your diagnosis. The pus is scattered through the gland, contained in the acini and excretory canals. Lancing always brings relief, lowers the temperature and promotes recovery.

Tablet Triturate Incompatibilities. Since our presentation of the pharmaco-therapeutic relations of the tablet triturates last year there has been in some quarters an awakening to the dangers that threaten medical practice through an extension of this form of medication.

Despite the fact that some manufacturers are exploiting the tablets "for all they are worth," they are being severely let alone by many physicians who were at first attracted by this "machine made," "cut and dried," "dicase to fit the remedy" plan of "doctoring made easy." The firm that enjoys the dubious distinction of having first introduced the tablets to the medical profession has replied to our criticism in their "Notes," but instead of answering a single one of the arguments advocated against the tablets, have laboriously endeavored to misrepresent our positions relative to the numbering of tablets. This firm proudly boasts that one of our statements relative to the use of the tablets by physicians, viz.: "That they are popularizing the form of self-medication; the tablets now being put up and numbered according to the disorder for which they are recommended," does not apply to its (the firm's) make, but that these observations are "based upon tablets which have gained prominence in the last few years." The statement was based upon the observation that non-medical persons select various combinations of remedies from titles by which these tablets are designated, as indicated by the particular disease for which they are recommended. Furnished with a catalogue containing description of remedies from "absorbent dyspeptic" to "vaginal astringent," it does not require much ingenuity on the part of any fairly intelligent member of the laity "to pick the winner," without paying the physician for making a selection for him.

In a recent catalogue issued by a certain firm there are about one thousand formulas, nearly one-half of which are designated by therapeutic titles. Most of these formulas show either a profound disregard for pharmacy, or a willful desire to mislead the medical profession. Some of these examples are of a character to bring the dispenser within the pale of the pharmacy law or an anti-adulteration act. A number of these formulas purport to contain highly volatile liquids, which to anyone the least familiar with pharmacy is shown on its face to be either a physical impossibility to combine in the form of a tablet, or after being combined or prepared, would from their very character rapidly volatilize and leave a more or less inert tablet.

Of this class are the tablets containing:

Ammonia, aromatic spirit of, in: Acetanilid 3 grs.: spirit of ammon. arom. 5 min.: soda mint, spirit ammon. arom. 2 grs.

Camphor combinations, in which the camphor sublimes on the sides of the containers: Anodyne: coryza Nos. 1, 2, 3: rhinitis: diarrhea.

Camphorated tincture of opium in the following: Astringent comp., 6 min., No. 2, 5 min.: croup, spasmodic, 5 min.: dys-

peptic (fermentative): camph., 10 min.: throat tablets, 10 min.

Heart stimulants, nitro-glycerin with tinctures of strophanthus, cactus grandif., belladonna, digitalis, etc.

Inflammatus, about 5 min. of tinctures, including Norwood's veratrum viride.

Sun cholera mixture, 3 min. each of tincts. opium, capsicum, rhubarb and spirits camphor and peppermint: 12 min. in one tablet. Will the *Sun* (N. Y.) recognize in this tablet its famous offspring?

It will be said that the medical constituents are present in such proportion as to represent these respective tinctures, spirits, etc.: this is the rankest kind of misrepresentation. But how about preserving nitro-glycerin in the tablet form, or tinct. valerian ammoniated?

The following are specimens of rank incompatibilities and "shotgun mixtures":

Anti-asthmatic: Potass. iodid, pot. brom., ea. 2 grs. Fl. ext. euphorbia pil. 3 min.: tinct lobelia, 2 m. Nitro-glycerin, 1-200 gr.

Antiseptic dyspeptic: Pepsin, bismuth and salol.

Cholera infantum: Lactopeptin, calomel, bismuth subnit., salol, zinc sulphocarbolate.

Imagine the advantage of nitro-glycerin with iodids and bromids, or digestive ferments with antiseptic phenol derivatives in the presence of free hydrochloric and lactic acids!

Mercuric chlorid, the most sensitive alkaloidal reagent known is combined with alkaloids, alkaloidal drugs in the following: Belladonna comp., bismuth opium comp., bronchial No. 2 (merc. iod.): diffusive malarial, "diphtheria and grip:" kali comp.: mercurius comp.

In the following a weak compound of phenol, salol, is combined with hydrochloric acid, producing new compounds, liberating phenol which no doubt in many instances has produced the most serious systematic disturbances if not fatal consequences: Bismuth catechu comp.: Bismuth subnit., salol, ea. 2½ grs.: powd. opium, catechu, ea. ½ gr.: oil cinnamon ⅛ m., acid hel. dil., ½ gr.

This is without doubt the worst specimen of a formula that has ever been perpetrated. Similar to these we find:

Hypophosphites with creosote, iron albuminate and arsenic; iron mercury comp. with quinin and strychnin; and "sore throat:" Tr. ferric chlor., 5 min., mercuric chlorid, 1-64 gr. in each tablet.

Blaud's in which ferrous carbonate is decomposed: also combined with arsenic: chlorodyne with nitro-glycerin, but without any chloroform.

As will be observed from these few examples every well-known pharmaceutic and chemic principle is violated. The fundamental therapeutic principle is also violated. Tablets when not composed of substances to be dissolved before they are administered, as "hypodermic tablets," etc., should be combined with such drugs as will exercise their local effect through the viscid vehicle that results from the solution of sugar, gum, etc., of which the tablet is formed: resinous and disagreeable tasting remedies are therefore not adapted to this form of medication. In the face of this we have tablets intended to be dissolved in the mouth composed of copaiba, aloes, extracts of hellebore, gossypium, ferrous sulphate, Venice turpentine, etc. Are there any remedies so repulsive to the palate?

But as though this were not enough, there are also listed "blank tablets:" white, yellow and pink, presumably to afford physicians an opportunity to try the "color cure" of the celebrated Vienna Institute. This "color therapy" is a relic of the "tabula smaragdina" of Hermes Trismegistus and has never been outranked in the history of charlatanism.

So it will be observed that not content with violating every principle of pharmacy and therapy some tablet manufacturers have also adopted the methods of the "fakirs." How any intelligent physician can countenance or permit himself to be per-

sueded by these adventurers and mountebanks to use these tablets in his practice passes comprehension. *Prof. C. S. N. Hallberg* in the *Graduate*.

A Foreign View of Our Mineral Waters. The *Deutsche med. Wochenschrift*, of January 23, contains an interesting and comprehensive study of the mineral springs of this country, with an array of statistics culled from the earliest work on the subject, 1831, to the latest report of the U. S. Geological Survey, which announces 8,843 mineral springs, with 785 analyzed. The writer, Dr. Beissel, of Aix-la-Chapelle, does full justice to the abundance and variety of these healing waters, but he says that only a few of them are regarded with confidence yet, as the country lacks physicians with the requisite knowledge and perseverance to exploit them. He also asserts that the American is not adapted to this kind of cure. He never will stay long enough at the place, and when he is there he lounges in an easy chair all the time. Those who understand how to derive the most benefit from a resort of this kind are not deterred by the trip across the Atlantic, and go to Europe for what they can not find yet at home. We have long known that our people are simply neglecting the great good that nature has so bountifully provided in our own mineral springs.

Fractures of the Clavicle.—The treatment of these fractures has recently entered upon a new era, that of surgical intervention and even wire sutures. Hassler writes to the *Lyon Médical*, Nov. 2 and 3, 1896, in regard to this, and offers the following suggestions:

First, he condemns absolute immobilization in an immovable apparatus, because it can not be done with any simple apparatus, because it leads to atrophy of the muscles to a greater or less extent, and also because it is not necessary to have absolute immovability in order to produce consolidation. We all know that there can not be a more difficult fracture to manage than a broken rib, and yet it grows together again very rapidly under a band of diachylon or a bandage around the body, notwithstanding the incessant movements of the thoracic region. He indorses and recommends early massage and relative immovability in an apparatus, in fractures from a direct cause, and in almost every case. In fractures of the outer or inner third there is the least displacement and attrition, and this method insures the most perfect cure. In fractures of the middle third, it is also the best method, for any phenomena resulting from compression of the blood vessels and nerves are absolutely exceptional. In fractures from a direct cause, in the outer and inner third early massage is indicated. Fractures of the middle third require this even more surely. The latter are the only fractures which indicate suture of the bone.

An operation and early suture of the bone are called for:

1. When there are serious primitive accidents, compression, contusion, laceration, inflammation of the vessels and nerves.
2. To forestall multiple complications resulting from an exuberant and vicious callus, which often appears from a direct cause involving the middle third, and especially where there is necessity for a more or less speedy return to work.
3. Where the bones lap very much and there is reason to fear a shortening of the whole bone, which would interfere seriously with the strength and movements of the arm.
4. When a fragment has been pressed down and can not be raised, or will not stay raised.
5. When the periosteum has been so crushed and mangled that blood has settled in and around the broken parts in large quantities, or when by the absence of any sound of friction between the ends of the bone there is cause to fear the interposition of some fibrous or muscular tissue or growth.
6. When the fracture is complicated with an open sore, probably infective. Surgical operation is indicated in this case, as much to secure disinfection as to insure proper coaptation with the suture.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.

W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, MARCH 7, 1896.

SCHOOLS AND ANTI-SCHOOLS.

The system of public schools is perhaps the one institution in which the American citizen takes especial pride. He considers it the corner-stone of the Republic, and for its preservation is prepared to make any sacrifice of blood and money. The traditional palladium has come to be invested with such a sacred character, that it is felt a sacrilege to criticise it; nevertheless, it is well for us to look at the conditions of to-day and inquire whether theoretic considerations as to universal education are really any longer practical possibilities.

When communities were small and luxurious establishments comparatively few, when wage-earners readily found employment and the children of the poor became prosperous men and women by insensible gradation, when reading, writing and arithmetic were the fundamentals of education and the methods of teaching were comprehensible by the mass of the young, there were plausible reasons for universal education; but the eve of the Twentieth Century finds enormous aggregates of human beings in which the refuse of dissimilar races, inheriting generations of degradation, bigotry and superstition, is in an immense proportion, and it is not possible to satisfactorily educate the offspring of such antecedents in the numerous branches which now form parts of the curricula of even low grade schools, especially by the complicated schemes of instruction elaborated by conventions of rival school teachers. Most of these children struggle through a term or two in a slipshod fashion and then go out to labor in sweat-shops, factories, and the huge retail stores, with no other practical result than perhaps a greater knowledge of English than they

could have acquired in their own wretched homes, where only the language of their parents is habitually spoken. As abject laborers and drudges, hewers of wood and drawers of water, they have in fact little need or desire for other knowledge than that of the language of the country and its minor currency, so that the perfunctory work of instructors in the de-tested school has been wasted in the attempt to teach them what they only imperfectly acquire and soon forget. The few who care to read apply their accomplishment to demoralizing literature that were better never read, and have no interest in this world or the next beyond what the priest or rabbi impresses upon them. For the half dozen in whom natural aptitude asserts itself, among the hundreds, the awakened intellect breeds contempt for the squalor and ignorance of their parents. The girls, moth-like, are attracted to the bright lights of the brothel and variety stage, where they find fine clothes, good food and more congenial associates than with their mothers and elder female kin, whose lives are daily toil and rough usage, the lot to which marriage in their own sphere surely dooms them. Even the children of the mechanic class, if ambitious, learn to spurn the vocations of their fathers, despise all manual occupation, and aspire to knowledge which unfits them for callings wherein they might find employment suited to their station.

How far the public school is responsible for the disappearance of the apprenticeship, through which boys grew to the mastery of the trades, can not be stated, but the older masters of every mechanical handiwork complain that their crafts are no longer recruited by well-trained and skillful young men. Proficients in Grecian history, algebra and physical geography do not care to learn how to handle a saw, mix paints or wipe a joint. Nor is over-education the only reprehensible tendency of modern schooling. Over-crowding with attendant faulty ventilation, bad light, constrained posture, protracted confinement and mental strain are doing their best to deteriorate the bodies of children, besides making their brains less able to digest and assimilate the over-seasoned food with which they are crammed. Dazzled by the beautiful mysteries of uranography and astronomy, puzzled by equations of two or more unknown quantities, and worried by intricate geometric theorems, they are left in blind ignorance of the beautiful structure and mysterious functions of their own bodies, or taught an expurgated infantile physiology, which, like the omitted Odes of Horace, stimulates a vicious prurient curiosity.

It is the legitimate office and imperative duty of the medical profession to indicate the remedy for a state of affairs that compromises the future of the people. If schools as organized and conducted hazard the health of the growing child and interfere with its nor-

mal development, they are objectionable; if they are to blame for the defective eyesight, crooked forms, nervous irregularities, and menstrual disturbances of girls, they had better give place to open air gymnasia and public play-grounds; if they tend to diminish the number of the artisan class, develop contempt for illiterate parents, aversion for their humble home and dissatisfaction with their station in life, and excite yearnings for meretricious finery and display, they are doing irreparable harm, and were better wholly supplanted by the monitory Sunday school and practical industrial school; if their results are only temporary, so that simple grammatical precepts make so little lasting impression that "You can't do no better," "I aint had no order not to go," and "Me and him was not in it," drop unconsciously from the lips of real-estate agents, clerks and others (the words are quoted as uttered) after their pupilage is over, the time thus wasted were better employed in the acquirement of some honest trade. It is only necessary to listen to the masses, ex-pupils of the public schools, to realize that the tuition they have received has been thrown away upon them. The veriest Chinese cooly, rapidly making the complex characters of his language in india ink, shames the labored, clumsy mis-spelled efforts of our corresponding lower classes. The province of the physician grows apace with the development of civilization. He may be powerless to compel individuals to do as they should and leave undone what they should not do, but he ought to direct the legislator, or himself fill the rôle of legislator, and indicate what is best for the several classes of the community.

The wretched home of the pauper alien child is, however, less potent an anti-school, operating to undo what the [State seeks to accomplish, than the grog-shops with which chiefly alien rum-sellers dot the main avenues of our great cities. Where there is one school house in many blocks, all four corners of intersecting streets have their anti-schools, offering resorts and lounging places for young and old, alluring them by their glaring lights and boisterous crowds from their cheerless homes, which fretful, overworked and ailing women unconsciously make more repellant. Whether as public health officer or member of special excise boards, the physician's voice should be heard in condemnation of the corner dramshop, which the political press indirectly sustains as a source of revenue for the nominal support of public charities. Pictures of brilliant red linings of the stomach, by which the public school health primer seeks to affright the pupil, are forgotten with the taste of the first sweetened exhilarating draught, and so long as this is accessible on every thoroughfare, the results of the school house, rational and useful, or specious and futile, are of no avail. Hence the school question involves the anti-school, and the medical sanitarian will properly insist upon considering them together.

THE SPECIFIC NATURE OF THE ANTITOXIC
SUBSTANCES IN THE BLOOD OF ANIMALS
RENDERED IMMUNE AGAINST THE
BACILLUS TYPHOSUS AND THE
BACILLUS COLI COMMUNIS.

The question of the identity of the bacillus of typhoid fever and the bacillus coli communis has been discussed and studied by bacteriologists for quite a long time without reaching conclusions that have seemed perfectly satisfactory to all interested. These two microorganisms are so similar morphologically and culturally that one is often spoken of as a variation from the other, both being either identical or very closely related. It is true that the colon bacillus produces gas in glucose media, causes an acid reaction with caseation in blue litmus milk, and that its bouillon cultures give the indol reaction; whereas the typhoid bacillus does not give these reactions, but every now and then one meets with bacilli that, from the manner in which they respond to these differential tests, seem to form connecting links between the colon bacillus, which is a normal inhabitant of the intestinal canal, and the typhoid bacillus, which is found in the body in typhoid fever. The question consequently presents itself in this light: Is the typhoid bacillus merely a variety of the colon bacillus group, the result of certain peculiar conditions or environments, or is it a microorganism strictly *sui generis*?

One of the fundamental principles of acquired immunity is that the antitoxins are specific; that is to say, they protect only against the microorganism by which they are produced. The antitoxin of diphtheria operates only against diphtheria bacilli, the antitoxin of tetanus only against tetanus intoxication. Consequently bacteriologists generally have become interested in the problem as to the specific nature of the antitoxins of typhoid bacilli and of the bacilli coli communis. Experiments in this direction have been made by a few investigators, but the results have not been absolutely uniform and finally decisive. Very recently LÖFFLER and ABEL have made this question the subject of a long series of careful, painstaking experiments, and the protocols of these experiments and the conclusions to be drawn from them are published in the *Centralblatt für Bakteriologie und Parasitenkunde* for Jan. 23, 1896. The results from their investigations may be summarized as follows:

1. The injection of increasing doses of virulent typhoid bacilli or colon bacilli into dogs produces in the blood of these animals certain substances that possess a specific protective power against the kind of bacillus by which they are produced.

2. The ordinary blood serum of untreated animals possesses a protective power against the ordinary fatal doses of typhoid and colon bacilli, and also against small multiples of the fatal doses. The exact dose depends upon the quantity of serum injected beforehand.

3. The specific action of the antitoxin in the blood of animals injected with bacilli becomes evident when such quantities of bacteria are injected as are multiples of the quantity against which normal serum protects.

4. The specific antitoxic action is also evidenced when a mixture of bacteria are injected with the serum.

5. The typhoid serum protects against a somewhat larger dose of colon bacilli than normal serum and, *vice versa*, the colon serum protects against a somewhat larger dose of typhoid bacilli than normal serum. This fact would seem to indicate a family relationship between the two kinds of bacteria.

6. The specific serum does not protect against the substances contained in the bodies of dead bacteria in any higher degree than does normal, ordinary blood serum.

7. Injection of normal serum into the peritoneal cavity of guinea pigs and then, twenty-four hours later, injection of twice the fatal dose of dead bacilli, produce in two weeks immunity against 100 times the fatal quantity of living typhoid bacilli.

THE MILK SUPPLY OF CITIES.

The Report of Drs. S. C. BUSEY and GEO. M. KOBER of Washington, D. C. on morbid and infectious milk, the advance sheets of which are now before us, constitutes a strong argument on behalf of the necessity for the sanitary control of dairies and of the milk supply of cities. According to the U. S. Census of 1890 the average annual production from sixteen and a half million milch cows was 5,209 million gallons of milk, 1,024 million pounds of butter and nearly nineteen million pounds of cheese. These large quantities give an indication of the extent of milk consumption, of the danger from an impure supply and of the temptation, from the monetary point of view, to the practice of fraudulent and more or less harmful adulterations. The official or legal standard composition of milk varies somewhat in different states and cities. It is lowest in New York, New Jersey and the District of Columbia, the requirements being 3 per cent of fat and 9 per cent of solids, not fat; it is highest in Massachusetts, 3.7 per cent fat and 9.3 per cent. solids, not fat. In England the standard is lower than in this country, 3 per cent. fat and 8.5 per cent. solids, not fat; but this class does not prevent adulteration by unscrupulous dealers. A common fraud appears to be the removal of cream and the addition of just enough separated milk to make a mixture that will come within the limit of the standard. Analyses of milk sold in New York city showed an average dilution with 33 per cent. water, the fraud amounting to \$10,000 per day. The State inspector for New York found an average of 12 per cent. of water added and 20 per cent. of cream removed.

According to Dr. SPIEGELHALTER, St. Louis, Mo., loses nearly \$2,000 daily by the removal of cream. The District of Columbia secured the passage of a milk bill last year. Many instances of the abstraction of cream were discovered by the public analyst; but the prosecutions failed because the law provided a penalty only when something had been added to the milk and did not take into consideration milk which had been deprived either in whole or in part of its cream. In the city of Chicago a bureau of milk inspection was created in 1892 and the milk supply of the city has been improved materially thereby; yet in 1894 of 12,093 samples examined 4,320 were below the standard.

The operations of the analyst under a law requiring milk to be of standard quality is a protection to the pocket of the public; but the report of Drs. BUSEY and KOBER shows that the dairies should be under sanitary control to prevent the propagation of disease by infected milk. This sanitary control should include inspection by competent veterinarians that the milk of all animals suffering from disease may be excluded from the supply. The diseases specially mentioned are tuberculosis, erysipelas, anthrax, pleuro-pneumonia, foot and mouth disease, septic and other fevers, specific enteritis and other intestinal disorders, rabies, tetanus, garget and other inflammatory conditions of the teats and udder. The milk of animals under treatment by medicaments and of animals five days before and five days after parturition is also held to be unfit for human consumption. The cow stables should be separate from other stock and poultry yards; they should be spacious, well ventilated and lighted, with cemented floors, proper drainage and clean hay or straw for bedding. The animals should not be allowed to feed on pastures with stagnant water or noxious weeds, particularly euphorbiaceous and ranunculaceous plants, nor upon the swill or products from distilleries, breweries, glucose factories, etc. The cows should be groomed daily and the teats and udders washed before milking with water previously boiled; and the requirements of cleanliness should apply with equal force to the milkmen, both in their persons and clothing. All persons engaged in handling the milk should be free from disease. Milk should not be permitted to leave a farm or dairy during the existence of typhoid fever, diphtheria or scarlet fever among the employes or inmates. The report cites 138 epidemics of typhoid fever, 74 of scarlet fever and 28 of diphtheria traceable to the milk supply. Of the 240 epidemics 187 were reported by English, thirty-one by American and nine by Scandinavian observers; while eight came from German, three from Australian and one each from French and Swiss sources. It is suggested that the infrequency of milk typhoid in France and Germany is due to the fact that milk is rarely used in

its raw state on the continent of Europe. To prevent loss under the restrictions necessary during the prevalence of infectious disease on a farm the utilization of the milk may be authorized for butter production after proper sterilization under the direction of the health board. The bottles for delivery should be cleansed by steam or a boiling solution of caustic soda, with subsequent washing in sterilized water. They should be closed with patent stoppers and properly labeled for specification of contents and identification of dealers. The retailer should be registered and be required to furnish a list of customers; and the names of the latter should be arranged on the index card system at the health office so that the simultaneous occurrence of infectious disease in families supplied by the same dairy or dealer may the more readily be discovered.

The needs of Washington city gave origin to this valuable report, which will be published in the report of the Health Officer of the District of Columbia; but there are few cities in the United States to which it will not give matter for consideration.

THE BROWN-SEQUARD METHOD OF TESTICULAR EXTRACT THERAPY.

The Brown-Séquardian theory of the tonic action of testicular extract has probably passed into the category of exploded fads in the opinion of at least the majority of the medical profession. It is a matter therefore of some interest when we see it brought forward again in a couple of scientific papers that make up nearly the whole of the latest issue of *Pflueger's Archiv*, and supported to a very considerable extent by physiologic experimental proofs. DR. OSKAR ZOTH and DR. FRITZ PREGL, of the physiologic institute of Graz, publish the results of ergographic (*i.e.*, dynamographic) investigations on the action of orchic extract in bodily fatigue and capacity, in which they find that, combined with exercise, the daily injections of this substance produce a very decided tonic effect, increasing the capacity for work considerably above that which would follow the exercise alone. This effect, moreover, was enduring and lasted for a considerable period after the discontinuance of the injections, and that it might, in short, be described as "tonic, eutrophic, and dynamogenic" in its effects on the system. DR. PREGL's experiments, moreover, were directed largely to the exclusion of the influence of suggestion, to which these effects had been referred by FORD, and that of the glycerin which had served as the excipient, both of which influences he concludes from his investigations can be considered as out of the question as causes of the phenomena.

DR. ZOTH suggests as a practical test, the employment of these injections by athletes and the observation of their effects. So far this does not seem to have been seriously carried out, and the experiment is worth a trial by trainers who might in this way add

something to our physiologic knowledge. A contribution of this kind from CORBETT, MAHER or FITZSIMMONS, would not, of course, elevate their occupation to the level of physiologic experiment, but would, perhaps, enable us to extract a little utility from what has at present not a single redeeming feature.

Another important collateral point is that of the value of the ovaries and testicles to the system otherwise than as simply organs of reproduction. If the injection of heterogeneous orchic extract has a direct tonic effect, what shall be the effect of the loss of the natural secretion by removal of the organ. This suggestion has, however, been already amply discussed in times past, but each new testimony to the truth, partial though it may be, of BROWN-SEQUARD's theory revives it, and its practical applications in surgery are numerous enough to give it at all times an interest. The question as to the possible effect of the ovary corresponding to that of the male gland has been discussed by VARIOT and others, and may be considered, as still, to some extent, open to discussion.

At all events, we can not say, with our present knowledge and the additions to it that are offered by investigations such as those here alluded to, as well as those of comparatively recent date by D'ARSONVAL, and others, that the subject is scientifically defunct, or that it has no standing in practical therapeutics with other methods and forms of serotherapy. Nor can we attribute, in the light of these latest investigations, the apparent beneficial effects of this method altogether to the influence of suggestion, as is done by FORD.

UPON GENERAL INFECTION BY THE BACILLUS PYOCYANEUS IN CHILDREN.

The bacillus pyocyaneus, obtained primarily as a contamination of pus in wounds, though definitely pathogenic for certain lower animals, notably rabbits, has but rarely been found as a primary cause of disease in man. Certain cases described by WILLIAMS and CAMERON (*Journal of Pathology and Bacteriology*, V. III, No. 4) being, beyond doubt, of this nature are therefore of more than usual interest. The three cases described seem to be the only ones recorded in which bacillus pyocyaneus has been found alone. There are many instances in which it has occurred in cases of septic infection in association with other microorganisms. The bacillus was found by these investigators in young marasmic children presenting a train of symptoms of emaciation, diarrhea, fever, muscular disorders, albuminuria and hemorrhages—the first and the last being the most prominent—indicating that the bacillus is distinctly pathogenic at an early age. How the disease originated, by what channel it gained entrance into the organism, is a matter of uncertainty. The authors refer to cutaneous lesions as a possible portal of entry, but such

lesions were not noted in any of these cases. The alimentary tract may have been the point of invasion. In two cases the bacillus was discovered in the contents of the small intestine. Signs of gastro-intestinal disturbance were among the first symptoms observed.

A careful bacteriologic examination of all cases of so-called "infantile marasmus" may demonstrate the distribution of this microörganism to be much more wide-spread and much more disastrous in early life than is generally believed.

"A GENERAL PRACTITIONER," OR ALL FOR MERCY'S SAKE.

As long ago as in the issue of this JOURNAL for Oct. 13, 1894, the promising merits of IAN MACLAREN, the now popular story-teller, were recognized. We there spoke of MACLAREN'S "A General Practitioner," as "a classic of its kind," although it was far from being in classic dress at that time; it was then to be found only in a penny paper of London, called the *British Weekly*. Since that time, the features of the Highland country doctor, DR. WEELUM MACLURE, have been made known all the world round in the "Bonnie Brier Bush" stories. And his physiognomy is everywhere recognized as that of one of the sturdiest and noblest medical characters that have ever appeared in fiction. If there is anywhere in fiction a more worthy, admirable and attractive personage than DR. MACLURE of Drumtochty, we will be thankful to have him pointed out to us. As his portrait has not, so far as we know, been seen in any medical gallery, we will here give space to a sketch taken from the earliest publication by MACLAREN:

"A tall, gaunt, loosely made man, without an ounce of superfluous flesh on his body, his face burned to a dark brick color by constant exposure to the weather, red hair and beard turning gray, honest blue eyes that look you ever in the face, huge hands with wrist bones like the shank of a ham, and a voice that hurled his salutations across his two fields, he suggested the moor rather than the drawing-room. But what a clever hand it was in an operation, as delicate as a woman's, and what a kindly voice it was in the humble room where the shepherd's wife was weeping by her man's bedside. He was 'ill pitten thegither' to begin with, but many of his physical defects were the penalty of his work, and endeared him to the glen in which he lived. That ugly scar that cut into his right eyebrow and gave him such a sinister expression, was got one night. His mare Jess slipped on the ice and laid him insensible eight miles from home. His form marked the big snow-storm in the fifties, when his horse missed the road in Glen Urtach, and they both rolled together in the drift. MACLURE escaped with a broken leg and three ribs, but he never walked like other men again. He could not swing himself into the saddle without making two attempts and holding Jess's mane. Neither can you 'warstle' through the peat bogs and snow drifts for forty winters without a touch of rheumatism. But they were honorable scars, and for such risks of life men get the Victoria Cross in other fields. MACLURE got nothing but the secret affection of the glen, which knew that no one had ever done one-tenth as much for it as this ungainly, twisted, battered figure, and I have seen a Drumtochty face soften at the sight of MACLURE limping to his horse."

The thing particularly interesting to medical men about the whole matter, is the claim made by the author, IAN MACLAREN, that his hero has been drawn from life, or rather, from the lives of several. In an address delivered before the Liverpool Medical Institute, he said:

"I am called upon to answer a question that has been often and fairly asked, Was there ever a doctor so self-forgetful and utterly Christian as WILLIAM MACLURE? To which I am proud to reply: On my conscience, not one man but many in Scotland and in the south country; I will dare to prophesy, also across the sea. It has been one man's good fortune to know four country doctors, not one of whom was without his faults—WEELUM was not perfect—but who, each one of them, might have sat for my hero. Three are now resting from their labors, and the fourth, if he should see these lines, would never have identified himself. Then I desire to thank my readers, and chiefly the medical profession, for the reception given to the doctor of Drumtochty. For many years I have desired to pay some tribute to a class whose services to the community at large are known to every countryman; but after the tale had gone forth my heart failed. For it might have been despised for the little grace of letters in the style, and because of the outward roughness of the man. But neither his biographer nor his circumstances have been able to obscure MACLURE, who has himself won all honest hearts and received afresh the recognition of his more distinguished brethren. From all parts of the English-speaking world letters have come in commendation of WILLIAM MACLURE, and many were from doctors who have received new courage. It is more honor than a new writer could ever have deserved, to receive the approbation of a profession whose charity puts us all to shame."

THE ATLANTA TRIP.

There is but one official special train from Chicago to Atlanta, and tickets should be purchased via the "Big Four" route. We have heard that one physician has sent circulars urging members to go with him by another line. The members will please remember that by patronizing the JOURNAL special they will have extra accommodations. The President, Board of Trustees, the Treasurer and other officers will be on board the JOURNAL special.

NEW INSTRUMENTS.

HOT WATER RECTAL SYRINGE.

Dr. Budin, of Paris, uses in his practice the little instrument

shown in the cut, to apply hot water in the treatment of hemorrhoids. It is all hollow, the base circle $2\frac{1}{2}$ c. in diameter, and the three curved branches meeting 5 c. above it. The

water enters through a tube fastened to some receptacle above, and sprays the hemorrhoids through a series of small openings in the branches. The olive shape given to the instrument is to facilitate its entrance in the anus, where the sphincter holds it in place. If the hot water causes pain to the surrounding parts he has the patient placed in a bath, so that the water mixes at once with some at a lower temperature as it runs out of the anus.—*Revue Internat. de Méd. et de Chir.*, January 25.

THE PHONENDOSCOPE.

This instrument is claimed by its inventors, Bazzi and Bianchi, to render perceptible all the normal and morbid sounds in the body, far more distinctly than the ordinary stethoscope. It renders audible the sounds made by the fetus, by the circulation, the muscles, etc., and also locates displaced organs by the noises made by their contents. It resembles a watch in appearance, and the two ear tubes shown in the cut can be multiplied indefinitely, so that several can be listening at the same time. In ausculting a large surface, the disc *B* is simply placed upon it, and the tubes placed in operator's ears. The tube *A*, is inserted into this disc when it is desired to circumscribe the auscultation. The contour of an organ can be accurately determined by the sound made by its contents through the tube, as the operator lightly manipulates it with his fingers.—*Journal de Méd. de Paris*, January 26.

PUBLIC HEALTH.

The Sanitary Advantages of Employment of Criminals.—The *Medical Examiner* states that the New York Medical Association, through Dr. Austin Flint, chairman of the Committee on Criminology "has sent out a circular to the profession urging its influence and coöperation in the passage of a law for the employment of criminals in prisons, on the ground that idleness leads to discontent, criminal speculations and propensities, and finally, instead of correcting the prisoner, it makes him more confirmed in his hatred of organized society when he leaves prison walls than when he entered. A copy of the 'concurrent resolution' which passed the legislature last year is inclosed. It must be reënacted at this session before it comes to a popular vote, as it changes a provision of the recently adopted constitution. It should have the unanimous support of the medical profession of this State."

Request for Information Regarding Aerial Convection of Variola.—Dr. Reginald Dudfield, the well-known Medical Officer of Health for Paddington, writes to the *Public Health*, London, seeking for information on the above subject, both from home and foreign sources. The question is a highly important one and some of our American sanitarians may be led to comply with the request conveyed in the following letter: "I shall be greatly obliged to you if you will allow me to appeal to all medical officers of health for information on the subject of 'Aerial Infection' of smallpox. I am seeking for cases that have come to their knowledge within recent years, and shall be glad of any references to published facts. I shall especially welcome information from those in charge of smallpox hospitals. I have not been able to discover any literature on the subject giving any account of similar spread of infection in connection with hospitals in foreign countries. Perhaps some of your readers may be able to give me references hereon? I am, sir, yours faithfully, REGINALD DUDFIELD."

Death by Lightning. The *Medical Examiner* has collected the statistics as to deaths by lightning, as follows: "For the four years 1890-93, according to the weather bureau, the number of deaths by lightning were 784, or an average of 196 a year. According to Mr. H. F. Kretzer, of St. Louis, Mo., for the five years 1883-87, there were 1,030 deaths by lightning, or an average of 206 per year. The work of lightning stroke is five times greater in the country than in the city. There is only one record to show what proportion of persons struck are killed outright, and that indicates that, out of 212, 74 were killed. Prof. McAdie thinks, therefore, that efforts to resuscitate should not cease till after the lapse of over an hour. Lightning brings about death by suspending animation through a paralysis of the respiratory centers. Stimulate the respiration, therefore, by the usual methods of artificial respiration, with or without the introduction of ordinary air, or of oxygen, or by means of the double bellows of Dr. Gibson."

Health Reports. The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Louisiana: New Orleans, February 15 to 22, 11 cases, 8 deaths.

Michigan: Greenbush Township, Ionia, Imlay Township, Riga Township, Saginaw, February 15 to 22, smallpox reported.

SMALLPOX—FOREIGN.

Antwerp, February 1 to 8, 2 cases, 1 death.

Cardiff, February 8 to 15, 3 cases.

Madras, January 17 to 24, 1 death.

Madrid, January 28 to February 11, 12 deaths.

Odessa, February 1 to 8, 3 cases.

Prague, February 1 to 8, 14 cases.

Rheims, February 8 to 15, 1 case.

St. Petersburg, February 1 to 8, 13 cases, 5 deaths.

Swansea, February 1 to 15, 1 case, 1 death.

Tuxpan, January 6 to February 1, 1 death.

Pernambuco, January 1 to 31, 203 cases, 52 deaths.

CHOLERA—FOREIGN.

Bombay, January 21 to 28, 5 deaths.

Calcutta, January 11 to 18, 48 deaths.

St. Petersburg, February 1 to 8, 7 cases, 5 deaths.

YELLOW FEVER—FOREIGN.

Cienfuego, February 16 to 23, 1 death.

Havana, February 13 to 20, 9 cases, 2 deaths.

Sagua la Grande, February 8 to 15, 5 cases.

San Juan, P. R. December 20 to January 17, 105 cases, 24 deaths.

Pernambuco, January 1 to 31, 5 cases, 3 deaths.

NECROLOGY.

J. HARRISON FORBES, M.D., of Brooklyn, died at St. Catherine's Hospital, that city, on February 6, from chronic cystitis culminating in acute nephritis. He was a graduate of the New York University Medical Department in the class of 1857, so that he had been in the profession nearly forty years. He was married, and his age, at the time of decease, was 76 years.

DR. DAVID W. MAULL one of the best known physicians of the State, died at his home in Wilmington, Del., February 22. Dr. Maull had been in failing health for some time. He was 65 years old, a native of Georgetown, Sussex County, and a son of Dr. George W. Maull.

Dr. Maull was educated in the schools of his native town, and was graduated from the Jefferson Medical College in 1853. He then served as surgeon on a steamer plying between Liverpool and Philadelphia. When the war broke out he enlisted in Company G, Delaware Volunteers and became a captain. After serving out his time he re-enlisted in Company E, and then became a surgeon. He was in nearly all the battles of the Army of the Potomac. He was promoted to be surgeon-in-chief of the Second Division of the Second Army Corps. After the war he settled as a practicing physician in Wilmington.

where he remained until his death. For six years he was the city vaccine physician. Dr. Maull contributed frequently to the medical journals. He also wrote an interesting memoir of General Thomas A. Smyth. In 1870 Dr. Maull was married to Miss Mary K. Buck. His wife and two children survive him.

MISCELLANY.

Charitable Bequests.—Under the will of Mrs. Mary Graydon, of New York, several charitable institutions are remembered with gifts amounting to \$8,000.

Population of Rio de Janeiro.—According to the *Brazil-Medico*, the population of Rio de Janeiro is now 600,000. For the first fortnight in December there were 542 births and 680 deaths reported, with the usual overwhelming percentage of deaths from tuberculosis that prevails everywhere nowadays.

The "Medical Faculty" Society at Harvard University.—The above named society is composed of undergraduates, many of whom are aspirants for a livelihood in the legal profession and a few in the ministry, whose constitution and by-laws require of them the perpetuation of practical jokes of a sort sufficiently outrageous to merit expulsion from college. How the society came to select so great a misnomer for its title has not been explained.

Amherst College Hospital for Students.—Mr. G. D. Pratt, of Brooklyn, and of the class of 1893 at Amherst College, has given to that institution a fund sufficient for the erection of a hospital for undergraduates. The work will be begun in the coming spring. The members of the Pratt family, which is one not altogether disassociated from the production of illuminating oils, are nearly all the time engaged in devising liberal things for Amherst College.

Roentgen Photograph.—The surgeons of Vienna and Berlin believe that the Roentgen photograph is destined to render inestimable services to surgery. Case after case is reported where unsuspected formations were revealed by the photograph, indicating slight operations which restored patients to health and cured deformities. Half an hour is the shortest exposure possible, and most require an hour. The electric apparatus required is so expensive, \$100 and upward, that few surgeons can use it yet in their private practice.

Music Graphically Recorded.—A simple little apparatus described in full in the *Revue Scient.* iv, 1, registers the energy, duration and form of each finger-touch upon the keys. A rubber tube runs under the keys, connecting with a Marey drum at each end. In studying music each one can read now for himself where he fails and where he succeeds; but the apparatus is especially recommended for psychologic examinations, where the patient is being examined without his or her knowledge.—*Centralblatt f. Phys.*, Jan. 25, 1896.

Einhorn's Stomach Register.—The inventor calls it a gastrokinesograph, or gastrograph. It consists of a small platinum ball moving freely inside a hollow ball a trifle larger. The patient swallows them, and then every motion, contraction, expansion, etc., makes the inner ball move also, which brings it in contact with wires fastened inside the large ball, thus opening and closing an electric circuit. There is less movement in the fasting than in the full stomach; dilation of the stomach and cicatricial stenosis of the pylorus seem to induce more violent mechanical action, while there is very little in ulcer ventriculi.—*Centralblatt für Phys.*, Jan. 25, 1896.

Anagyrin Localized in the Grain.—The *anagryis fetula* produces an alkaloid called anagyrin, which is derived from its grain-like fruit. Guérin has been making a special study of it recently and announces that combined with iodid or iodized potassium it produces a granulated precipitate, soluble in hyposulphite of soda. Combined with perchlorid of iron, a yellow-orange coloration is produced. With iodid of bismuth

and potassium, a reddish-brown precipitate is formed; with iodid of mercury and potassium, a yellowish-white precipitate, and with picric acid, a yellowish precipitate. He queries whether it may not be identifiable with cytisin, like ulexin, sophorin and baptitoxin.

Imaginary Dyspepsia. The *Gaz. degli Osp. e delle Chir.* of January 25, describes a curious case of a robust peasant woman suddenly attacked with acute dyspepsia, wasting away from actual starvation, until she entered the hospital for treatment, almost a skeleton. Examination failed to reveal any cause for gastric disturbance until the physicians became convinced it was an imaginary trouble, and treating her accordingly: she was soon discharged cured. Her idea that she could not digest did actually prevent her food from assimilating. When she left, her daily rations were twenty eggs and a liter and a half of milk, which she digested perfectly.

City Civil Service Notice.—The City Civil Service Commission will hold an examination in the Council Chambers Saturday, March 14, 1896, at 1:30 P.M., for the position of inspector in the City Health Department. All candidates must be graduates in medicine and present evidence of recognition by the Illinois State Board of Health. Applications in proper form must be filed at the office of the City Civil Service Commission, Chicago, not later than Wednesday, March 11, at 12 o'clock.

WM. CUTHBERTSON,
M. L. GOODKIND,
R. A. EDWARDS,
S. C. PLUMMER,
JOSEPH R. HAWLEY.

Strychnin Dispensed for Phenacetin; Heavy Penalty.—The London correspondent of the *American Practitioner and News* writes of a remarkably heavy penalty administered in an English court, following a death due to an error in dispensing. He says: "A short time ago a Birmingham manufacturer died from taking strychnin supplied to him by a retail chemist for phenacetin. It was shown at the time that the retail chemist supplied only that which had been furnished to him by the wholesale chemist. At the present Birmingham Assizes an action was entered by the widow of the deceased to recover damages, both the wholesale firm and the retailer being sued. The plaintiff's case was concluded on the second day of the trial, when counsel stated that terms had been arranged. The record was withdrawn, the wholesale chemists paying plaintiff about \$14,000 and costs, the retailer paying his own costs. The representative of the wholesale chemists explained that how the mistake arose was a mystery, and the defendants desired to act honorably. The judge expressed his satisfaction with the terms stated."

Provisions for Treatment of Paupers.—Several points of considerable importance to physicians have been decided by the supreme judicial court of Maine, in the case of Goodrich vs. City of Waterville. This decision was rendered May 21, 1895, but has just been reported in the advance sheets of 33 "Atlantic Reporter," 659. The court holds that all persons acting under the employment of town or city officers must take notice at their peril of the extent of the authority of such officers. When a town or city has already provided for the medical treatment of its sick paupers by the election of a town or city physician, and he is ready and willing and competent to attend a sick pauper, so that no necessity exists for employing any other, it is undoubtedly the duty of the overseers of the poor to call him when one of the paupers under their care is sick and in need of medical treatment. In such a case the overseers have no authority to employ any other; and, if others are employed, they are chargeable with notice that they will have no right to call upon the town or city to compensate them for their services. Furthermore, it being provided by statute in Maine (Rev. St. c. 3, sec. 36) that "no member of a city government shall be interested, directly or indirectly, in any contract

entered into by such government while he is a member thereof," the court holds that, one of the plaintiffs being a member of the city council, no action can be maintained to recover for medical services rendered by his firm to a pauper of his city. It is a contract in which a member of the city government is directly interested, and for that reason is void by the statute.

Continuances for Sickness. In a prosecution for a felony, the defendant applied for a continuance on the ground of his sickness and disability. The good faith of the application was challenged by the prosecution, and on its request a committee of physicians was appointed by the court to visit the defendant and report upon his condition, which they did; and they were examined on the subject orally in open court. Afterward another committee of physicians was appointed to treat the defendant until ready for trial, and to see that nothing was given him except under their direction, and they took charge of the defendant accordingly for some days, when, the case being again called, another application for continuance was made, which, upon hearing evidence, the court overruled, finding that the defendant was able to be placed upon trial, and was in a fit and suitable condition physically to be present. On appeal, the supreme court of Kansas holds, *State vs. Rogers*, decided January 11, 1896, that there was no abuse of discretion in overruling the application for a continuance.

Comparative Frequency of Fractures as Shown by U. S. Marine-Hospital Reports (1878 to 1894 inclusive).—Five thousand four hundred and fifty-six fractures were distributed as follows:

Vault of skull.	131	Fibula (alone).	382
Base of skull.	43	Bones of foot (not specified). . .	147
Facial bones.	239	Cervix femoris.	12
Inferior maxilla.	65	Humerus.	205
Hyoid bone.	4	Bones of forearm.	728
Sternum.	11	Radius (alone).	114
Clavicle.	305	Ulna (alone).	55
Scapula.	61	Bones of hand (including) carpal, metacarpal and phalanges. . .	499
Vertebrae.	40	Bones of foot (including) tarsus, metatarsus and phalanges. . .	41
Ribs.	965	Bones of the leg, together and singly.	1,251
Pelvic bones (not specified). . .	43	Bones of forearm, together and singly.	897
Coccyx.	1	Bones of foot, specified and not specified.	188
Sacrum.	1		
Femur.	411		
Neck of femur.	29		
Patella.	113		
Both bones of leg.	539		
Tibia (alone).	330		

Of 570 fractures, occurring after 1886, the bones of forearm were specified as follows: Radius, 244; ulna, 139; both bones of forearm, 187.

Of 112 cases, recorded after 1886: Metatarsus, 47; phalanges, 39, tarsus, 26.

Deaths from fractures and complications:

Vault of skull.	44	Pelvis.	5
Base of skull.	23	Humerus.	5
Facial bones.	3	Forearm.	6
Hyoid bones.	1	Carpus.	1
Clavicle.	3	Femur.	20
Ribs.	7	Tibia.	2
Ribs and spine.	1	Leg, both bones.	19
Spine.	15	Metatarsus.	1
Scapula.	1		
		Total.	154

Acute Fatal Dilatation of the Stomach. Boas distinguishes two forms of acute gastric atony, the first caused by the overcrowding the stomach and the consequent putrefaction and formation of gases; and the second produced by some acute disturbance in the stomach musculature. Bamberger asserts that gastric atony is very apt to follow or accompany diseases like typhus, cholera, puerperal fever, chlorosis and tuberculosis. But this gradual degeneration is more a myasthenic atony than a dilatatio ventriculi. Albu writes to the *Deutsche Med. Wochensh.* of February 13, quoting the above and other authorities, and then describes the case of a young man who came to the hospital with a typical scarlet fever, from which he was recovering nicely when suddenly, on the eleventh day, with no errors in diet, he was taken with vomiting, pain and distention of the stomach, which swelled and puffed up the abdomen with it, accompanied by apathy, coma and then delirium and death. No peristaltic motion was visible, and the vomiting ceased when stomach had attained its largest dimen-

sions. Science has only recently learned to recognize the toxic nature of the paralysis which occurs in the different parts of the nervous system after various acute infective diseases. The influence of some toxic substance or substances on the nerves which communicate with the musculature of the stomach is the writer's conclusion from the case above.

Bravery of a Medical Man. The *Medical Press and Circular* for February 5 has the following account of the brave action of a Welsh physician:

"The late disastrous explosion at Tylorstown, South Wales, was the occasion of much courageous rescue work. Among other noteworthy incidents of the kind, we are pleased to chronicle the bravery of Dr. Thomas Morris, the medical officer of the collieries where the disaster occurred. As soon as the state of the gearing permitted the descent of the rescue party, the doctor went down and spent the whole day underground, where he did much service among the injured survivors. In the afternoon he was summoned to a wounded man who lay a mile and a quarter along one of the workings. To reach him the doctor had to scramble and struggle as best he could through many parts of the wrecked workings. The injured man was unconscious, and was kept alive by artificial respiration, conducted at intervals on the wearisome and dangerous journey back to the pit's mouth. The workmen of the district at a local meeting passed a resolution thanking Dr. Morris for the noble efforts he had made in the work of exploration, and in saving the life of the collier Phillips. This kind of heroism is less conspicuous but not a whit the less sterling than deeds of bravery done upon the battlefield."

Liability of Charitable Corporations for Negligence of Servants.—Under authority of the legislature of the State of Connecticut, the Waterbury Hospital was organized "for the purpose of furnishing medical and surgical care, nurses, medicines and food to patients suffering from disease or from injuries." It has no capital stock, and its members can derive no profit from the corporation. These features, the supreme court of errors of the State says, clearly indicate a "charitable corporation." To this hospital Hugh Hearn applied for treatment of a fractured kneecap. He subsequently sued it for damages for injuries alleged to have been caused by the unskillful and negligent treatment which he received at the hospital. (*Hearn vs. Waterbury Hospital*.) Judgment was rendered for the defendant, which the above court affirms. Its decision, though handed down April 5, 1895, has but just been made accessible in the advance sheets of 33 *"Atlantic Reporter,"* 595, and is of unusual interest, not only because it is the first decision of the question in that State, but because of the exceptional length at which the court discusses it. The result is made to depend on the one question of liability of such a hospital for the negligence of its servants. The court thinks the law does not justify the extension of the doctrine of respondeat superior, making the master answer, to such a case as this. It deems it enough to say that a charitable corporation of this character, whatever may be the principle that controls its liability for corporate neglect in the performance of a corporate duty, is not liable, on grounds of public policy, for injuries caused by personal wrongful neglect in the performance of his duty by a servant whom it has selected with due care; but in such case the servant is alone responsible for his own wrong.

Autodigestion of the Human Pancreas. Chiari (*Archiv für Heilkunde*, B. xvii, 1896) publishes a study of autodigestion of the pancreas and reaches the conclusion that very often there occurs a post-mortal digestion or necrosis in the pancreas; this may also occur during the agony, and even, as described by Chiari in two cases, during the full bloom of life in which the autodigestion showed itself in the form of local necrosis of the pancreas around which a reactive chronic interstitial pancreatitis developed. These areas were free from bacteria. The conditions in the pancreas would consequently be similar to those in the stomach in which we recognize a post-mortal, an intra-agonal, and are intra-vital self-digestion. Several authors have already referred to possibility of the pancreatic

tissue digesting itself. In 1879 Klebs expressed himself as believing that the cause of hemorrhages into the pancreas might be found in the corrosive action of its secretions. Gussenbauer, Salzer and Tilger all refer to the likelihood that this process may play an important part in the production of pancreatic cysts. Chiari believes that self-digestion will explain many obscure cases of pancreatic hemorrhage, and of gangrene of the pancreas, the bacteria from the intestinal tract finding a suitable soil in the necrotic pancreatic tissue.

Why does not the pancreas always digest itself? Obstruction to outflow of pancreatic juice does not cause digestion as shown by the experiments of Senn and Heidenhain in which obstruction of duct of Wirsung was artificially produced without direct destruction of the glandular structure. In all probability the cells of the pancreas must first be changed in some way before digestion can occur.

Pustula Maligna followed by Hemorrhagic Septicemia Produced by a Specific Bacillus.—We know for a fact that the anthrax bacillus often prepares a soil for an invasion by another kind of bacillus whose action is usually beneficial. But occasionally the secondary bacilli prove virulently poisonous. Babes and Pop, of Bucharest, describe minutely such a case in the *Deutsche med. Wochenschrift* of January 23. A pustula maligna on a man of 30 was followed by a fatal hemorrhagic inflammation of the jejunum and multiple hemorrhages in lungs, pleura, kidneys, etc., with a notable absence of the anatomic pathologic indications of splenic fever. Bacteriologic tests showed anthrax bacilli present in the carbuncle and nowhere else. Later they disappeared and were replaced by another bacillus which invaded the whole organism and were encountered everywhere at the autopsy. The writers believe that this second bacillus belongs to a great group of saprogenic bacilli which includes many of the better known abdominal and putrefaction-producing bacteria. The cultures showed that it resembles the bacillus coli and the typhoid bacillus, but is usually more slender, and differs from them also by the way in which it spreads out on agar agar in a thin, homogeneous transparent layer, with long finger-like projections on the borders, by its liquefaction of gelatin, by its swelling and blister-like formations, by its being sluggishly motile and also by its extensive formation of by-products. Different animals inoculated with this virulent bacillus furnished interesting experiences which are described in detail, all of them showing the same peculiar tendency to hemorrhages.

Elsner's Method of Early Bacteriologic Diagnosis of Typhoid Fever.—Elsner announces the discovery of a means to distinguish the typhoid bacillus in the evacuations and differentiate it from the bacillus coli in twenty-four to forty-eight hours. He experimented with bouillon made from fish, from reptiles, beets and all kinds of vegetables, until he found a medium that will only make cultures of the typhoid bacillus and bacillus coli, and these cultures present such characteristics that they can be differentiated with the naked eye. His medium is prepared as follows: He boils gelatin with a decoction of potato and adds a triturated solution of soda in sufficient quantity to produce the same degree of acidity as in Holtz's medium. This he filters and sterilizes. The liquid is then poured into Erlenmeyer tubes and completed by the addition of iodid of potassium, in a ratio of 1 to 100. The culture is then made and poured out on plates. In twenty-four hours there are colonies of bacilli coli, and in forty-eight, the typhoid colonies develop, easily recognized as small transparent points, finely granulated, in the midst of the luxuriant brownish growth of the bacilli coli. This medium is exceedingly susceptible to cultures, experiments showing that the typhoid colonies would develop when the liquid only contained one part culture to eight thousand million parts liquid. Other scientists who have experimented with this new medium find it all that Elsner claims.

They also call attention to the fact that the typhoid bacilli diminish in numbers as convalescence progresses, and if their numbers keep up, a relapse may be expected. — *Revue Internal de Méd. et de Chir.*, January 25.

To Ward off Malaria. Since the disastrous Madagascar expedition, the French have been studying how to fight malaria in the countries where it prevails. The conclusions of a recent treatise on the subject by Dr. Maurel, are: 1. To administer quinin in preventive doses, .75 to 1 gram, at intervals of four or five days, is considered sufficient. 2. As the germs are in the atmosphere and are breathed into the lungs, troops must be commanded to keep their mouths shut when marching, as breathing air filtered through the nose, is much less dangerous. 3. Malarial districts, marshes, etc., must be avoided and habitations located 200 to 300 meters above them where possible. No work should be permitted in the heat of the day. Houses should be surrounded with trees at least their own height, and windows should be glazed to keep out the evening dew. Exposure to this dew must be strictly avoided as far as possible. 4. Europeans must not attempt to cultivate the ground in the intertropical regions. It is death to them, but does not injure negroes or other natives, who should be secured for this purpose. If Europeans respect this law of nature, their malarial attacks are much less frequent and rarely fatal. Even in hotbeds of malaria, Europeans can conduct a campaign or carry on business enterprises if they obey the above regulations. Drainage, etc., will in time partially, if not wholly, reclaim the most malarial countries, but the Caucasian must always bear in mind that he can direct, oversee, practice a profession, fight, paint or do anything he chooses except till the soil. This treatise will soon be followed by another on preventive therapeutics. — *Bulletin of the Acad. de Méd.*, January 21.

Tuberculosis of Parrots. Straus, whose extensive researches upon tuberculosis in various animals as well as in man is well known, says that tuberculosis in the parrot presents several features which differ from those peculiar to the classical form of avian tuberculous disease.

Tuberculosis is not uncommon in parrots. Froehner found that in 154 parrots treated at the veterinary school in Berlin 56 were proven by demonstration of the bacilli to have tuberculosis. Cadiot found eleven out of thirty-five parrots to have tuberculous lesions. Cadiot made inoculations with the tuberculous material from the parrot into guinea pigs and there followed an eruption of general tuberculosis. In the parrot the disease is characterized by the frequent involvement of the skin and of the mucous orifices, whereas in fowls tuberculosis prefers the digestive tract and its adnexa. The tuberculous lesions of the parrot consist of grayish or brownish tumors, often having a horny appearance. The swellings may be multiple. The skin of the head is the seat of predilection. The internal organs are involved only occasionally, the lungs oftener than the liver and the intestines. The parrot, living in a state of captivity, not coming in contact with other birds, but being in close contact with human beings, is most likely infected with the products of human tuberculosis. It would consequently be of interest to determine the exact nature of tuberculosis in parrots, whether it is simply the result of transplantation of human tuberculosis or presents the characters of ordinary avian tuberculous disease. Straus examined two cases of parrot tuberculosis with this object in view and found that the disease presented exactly the same features as tuberculosis in man. This was shown by the result of inoculation into guinea pigs in which it produced the lesions that follow the introduction of human tuberculous products and those peculiar to the avian. Inoculations of the lesions in parrots into the peritoneal cavity of fowls were without effect. It consequently seems clear that it is through its contact with man that the parrot becomes tuberculous. When passed through a bird like the parrot human tuberculosis is not changed into avian but retains its fundamental characteristics.

Langendorff's New Method of Keeping the Hearts of Animals alive for Scientific Investigation. This method does not supersede Martin's method, but supplements it, with especial reference to the study of the cardiac muscles, their innervation, etc. The animal (dog, cat, rabbit) is killed by bleeding. The blood is defibrinated and filtered into the injecting flask, which is kept at the temperature of the body. Then the heart is cut out and a tube inserted in the rising part of the aorta which is fed from the flask of blood. The heart is then put in a warm place and blood forced in by pressure until the semilunar valves close and it is impossible to force open the left chamber. The heart stands upright on a special standard contrived for it, with a hook in the apex to hold it straight. The blood to be injected must flow at a certain pressure, equally, and for a long time, which requires some ingenuity to accomplish. But as soon as it begins to flow through the coronary arteries the heart begins to pulsate as in life. Haller's theory that it is necessary to have blood flowing through the chambers to produce pulsation, is proved erroneous by these experiments, in which they are empty of blood. The heart can be made to pulsate in this way hours after death, or until the heart muscle becomes too stiff. Langendorff noticed: 1. That poisons, like muscarin, atropin and the salts of potash produced their usual effect on the heart. 2. That, like the frog's heart, the pulsations were more rapid the warmer the temperature. 3. That the effect of tetanizing is complete: only in a very few cases did the vagus fail to respond. 4. As the action of the semilunar valves ceases, the heart makes but one sound, which coincides with the systole of the chambers. 5. The same as with the frog's heart the pulsations will cease if salt solution is made to flow through the arteries instead of blood. But a renewal of the supply of blood will start the pulsations afresh even if the heart seems almost motionless. 6. Electric shocks produce a refractory phase the same as with a frog's heart; tetanizing produces "waves" as in living animals. 7. These experiments also contradict the theories of Bezold, Cohnheim, Schulthess and Reclberg that obstruction of the coronary produces "waves" and then stops the heart altogether. Stoppage of the circulation never produces "waves," and a fresh supply of blood introduced always starts up the heart again at once.—*Centralbl. für Phys.*, Jan. 25, 1896.

Sale of Business with Agreement not to Practice Medicine. A practicing physician in Anniston, Ala., sold, for \$125, his horse, buggy, and medical practice, agreeing as a part of the contract, not to practice his profession in that city for two years, and making the further stipulation that in case of failure to comply with the agreement he would pay, as a forfeiture, the sum of \$200. In a decision rendered Dec. 17, 1895, the supreme court of Alabama, *McCurry vs. Gibson*, upholds this contract. It says that it is settled by the authorities that the purchase by one party of the property and good will of the business of another furnishes a sufficient consideration for an agreement by the latter, in enhancement of the value of the good will, not to compete with him in the conduct of the business. The rule is the same when a physician sells his property and practice to a professional brother. It was at an early day supposed that the consideration in such cases must be adequate, that is, equal in value to the restraint imposed; but this idea has been exploded. The contract in this case showed upon its face a sufficient consideration, and the court will not assume the task of ascertaining whether the party selling out made a good or a bad bargain. It contained a valid agreement for the payment of \$200, as fixed damages, for its breach. And that stipulation is no barrier in the way of granting relief by injunction, which is a negative specific performance of the contract: the purchaser having his election to sue for damages or to have the agreement performed according to its terms. Neither is it necessary to show that a physician is actually practicing before he can contract for the property and good will of another, nor to show that he had at

that time complied with the legal requirements for practicing medicine at that place. A license is not necessary to making such a contract, especially where it does not appear that an infraction of the law with regard to practicing medicine is contemplated. Furthermore, in Alabama, it would seem that it is not required that a physician have his certificate of qualification recorded in a county to which he removes after it has been issued and once properly recorded.

Doctors Should Attend the Primaries.—At a recent meeting of the Physicians' Club of Chicago, "The Management of the Health Department of Large Cities," was discussed. Dr. Truman W. Miller said: "I do not care to say very much on this subject. I have attended several meetings and have heard discussions, all tending in the same direction, the laudation of each other to the detriment of somebody else. The preceding speakers have called emphatically for *action*. I have heard that call for many years. I have seen none of it. Your Chairman was kind enough to say that I was a practical man. I believe that has been my reputation, and I do not want to lose it. You discuss this subject very freely, but you accomplish nothing. It is the old and oft-repeated story, the ins and the outs. Those that are in try to stay in; those that are out try to get in. Gentlemen, if you ever wish to do anything in this matter, why don't you go at it like men and do it. Take hold of it and do something, instead of having little gatherings of this kind, with a scattering few from different parts of the city. This is a subject that needs to be discussed in the gravest and most careful manner. Devote a little of your time to putting men in these places who are competent to fill them and who are able to do the work wisely and well, and not simply spend the most of your time in trying to get the places yourselves. I speak frankly about this matter. We who are present are too small in number to speak for the entire profession. The medical profession of this city has a voice, and if used in the proper place, we can carry anything in this city without a doubt. But, gentlemen, it is not at the Physicians' Club that we shall succeed in doing it. It is at the places where most of you never go, the primaries and the polls. You do not go there with your friends and neighbors. If you did and performed your duty as citizens, you could sweep every primary in the city. If you will talk with the majority of your friends and neighbors and tell them what you think is right, regarding the health department of a great city like this, and by whom it should be run, you can accomplish a great deal. But do you ever do it? You wait until other men are elected to these positions, then it is too late. Doctors should come out like men, state their position, and enforce it. Look at the community in which we all live. Look at the people you can control: how many votes you can poll in the primary; how many people you can take along with you to carry anything that is worthy of attention. There are other things besides health matters that require attention, but they must be considered altogether. I shall be only too glad to join all of you if you will come together and make a decided stand as to what you are willing to do and what you desire to be done. If we work jointly we can change the election at any time in spite of any program that may be laid out by anyone in this city. It can be overturned at once and carried our way easily. I deprecate discussions which have for their object the criticism of the business man now at the head of the health department as well as his assistants. The important question for us to discuss is, Who shall be their successors? Go to the primaries and vote and try to put men in these positions who can creditably and thoroughly fill them. It will redound far more to your credit to do this than to waste time in fruitless criticism of the present officers of the health department. Interview the candidates for aldermen yourselves, attend the primaries, state clearly your views in the ward clubs of your respective parties, and then you will accomplish what we all desire to see: A thoroughly reorganized health department for Chicago and a competent medical man at its head.

A Medico-Literary Career.—Dr. Talcott Williams, writing for the *Book News*, February, gives an interesting sketch of the career of Dr. Eugene Coleman Savidge, a newly risen luminary in American literature: Dr. Savidge, though hardly more than thirty years of age, has already attained an enviable position in the two distinct yet compatible fields of medicine and letters. Notwithstanding active railroad work, he traveled extensively in America, studied medicine, edited the *Expressman*, a journal published in New York: wrote "Wallingford," a novel, and contributed many descriptive articles to various newspaper syndicates. Resigning from the railroad, with unusually warm tributes from his chief, he went to Philadelphia and wrote the "Gallery of Eminent Men," and also the Pennsylvania names for Appleton's "Encyclopedia of Biography." "The Life and Times of Brewster" followed, and was a signal success; Chief Justice Paxson pronounced it "the best and most interesting book of the kind he had ever read;" the Philadelphia *Ledger* and *Record* stamped it as "a model piece of work," and the New York *Times* and *Tribune* characterized it as "inspiring." With the proceeds of his literary work he completed his medical studies in Paris. Dr. Savidge has achieved distinct success in "The American in Paris," his last book. Says the New York *World*: "'The American in Paris' barely escapes being a great novel and the American novel." It is certainly the best of the year on either side of the Atlantic, not even excepting Zola's 'Lourdes,' or Crawford's 'Casa Braccio.' As a historical novel of our own time, nothing like it for boldness and audacity has ever been printed. Dr. Savidge is one of the most successful of New York's younger gynecologists. He is an accomplished linguist, having taken his degrees in letters and sciences, as also his first doctorate, from the University of France. He was externe at the Charity Hospital, Paris, and subsequently resident gynecologist to Roosevelt Hospital and the Sloane Maternity Hospital of New York, and is now one of visiting gynecologists to Roosevelt Hospital (out department), and has just been elected attending gynecologist to St. Mark's Hospital, New York." Dr. Savidge's earlier journalistic work comprised studies of American localities and peoples, including the Mormons, the Creoles, the Indians, the negroes, miners and frontiersmen, and the vintage and irrigation interests of Southern California—studies which were combined with the quest of business ends for the railroad. His biographical work reaches nearly one hundred biographies, and was undertaken with the specific design of meeting and studying successful American men.

Practical Notes.

Salolized Vaseline.—Salol dissolved in vaselin does not irritate the skin nor inflame diseased tissues, while yet it retains all its healing and antiseptic properties. Colombini recommends the use of it especially on ulcers. —*Nouv. Remèdes*, February 8.

Asafetida in Gynecology.—Warman recommends this drug in the *D. Frauenarzt*, August, 1895, as invaluable in soothing irritation in the uterus, counteracting a tendency to abortion and relieving the frequent constipation and nervousness of pregnant women. —*Nouveaux Remèdes*, February 8.

Total Thermo-cautery of the Uterus.—A Hungarian medical journal describes an operation where the uterus was entirely removed, without the use of scissors or knife or the loss of any blood. A cancerous infection of the uterus rendered these precautions necessary to prevent secondary infection. The ligatures were seized with the hot instruments but were not detached for forty-eight hours. —*Centralbl. für Chir.* January 25.

Pancreatic Cyst and Twisted Kidney.—A pancreatic cyst recently operated upon in Dresden discharged 3500 c.c. of a greenish brown fluid strongly impregnated with cholesterin. In growing it had compressed the kidney $\frac{1}{3}$ to $\frac{1}{4}$ its normal size, and twisted it half around. Complete recovery followed. The opening was made from the right twelfth rib, curving around to near the spina ant. sup. The cyst lay in the intraperitoneal region and was not tapped for several days after opening had been made, to promote adhesions. —*Centralbl. für Chir.*, January 25.

Malarial Eruption.—A woman of 40 was suddenly attacked with a peculiar eruption on the nose, which discharged a serous fluid every morning with a burning sensation, and grew better

toward afternoon. She had been living in a malarious region and had suffered from intermittent pneumonia which only yielded to large doses of quinin. Guided by this, quinin was ordered for the eruption, which had been treated in vain with almost every other known remedy. In forty-eight hours the congestions had ceased and in four days the entire eruption had vanished. —*Ther. Wochenschrift* of January 26.

Pressure Necessary to Absorption.—Hamburger of Utrecht has been making an exhaustive study of the processes of absorption in the tissues with specially prepared apparatus, experimenting on dogs and also with artificially prepared membranes. He announces that there is no absorption if there is no pressure, and that absorption in the intestines is directly dependent upon the pressure. This pressure is produced by respiration, the peristaltic action of the intestines and by the weight of the bowels as they press against each other. —*Centralbl. für Phys.*, January 25.

Guaiaic in Oil as a Local Anesthetic in Optical Operations.—One gram of the guaiaic crystals in 10 grams of sterilized oil, is the proportion recommended by Belencontre, quoted in the *Gazette Médicale de Liège*, February 6. He uses a gram syringe supplied with a platinum needle. This he inserts into the tissue, especially if the lid is to be operated on, carrying it as deep and parallel to the path of the knife. While withdrawing the needle he pushes the piston so as to distribute the oil smoothly and regularly while using the smallest possible amount. Three drops of the oil will suffice in most cases, and Belencontre has never used over fifteen. In severe inflammation, however, the pain of the injection is almost equal to that of the operation. Guaiaic is useful, however, in certain cases, as it produces no general nor local accidents, and can be used on children or where there is cardiac trouble when cocain is counter-indicated.

Malaria Treated with Chlorhydrate of Phenocol.—The *Méd. Obzo-riénie*, 1895, No. 9, reports three cases of malaria, upon which quinin produced no effect, successfully treated with the chlorhydrate of phenocol. In first case fever disappeared after third powder (0.6 gram each) and complete recovery followed the twenty-sixth. Second case, intense neuralgia of the left trigeminal from 8 A.M. till 6 P.M. relieved by two powders and completely cured with twenty-four powders, same dose as above, three powders a day. Third case, a daily hectic fever with such exhaustion that incipient tuberculosis was suspected. No benefit from quinin, arsenic or methylen blue. Fever ended with fourth powder, same dose as above, and complete recovery coincided with twenty-fifth powder, equal in all to fifteen grams chlorhydrate of phenocol.

Creosote in Tuberculosis.—At a recent meeting of the Soc. Méd. des Hopitaux the use of creosote in tuberculosis was discussed, and some members claimed great advantages from its use, while others asserted that the improvement came from the better care and food received by the patient in the hospital, and not from the treatment. All agreed that it did benefit the scrofulous form, and that its use was counterindicated wherever there was fever, dyspepsia, or a tendency to congestions, hemoptysis, or tachycardia. Burlureaux warmly endorsed the use of creosoted oil in all other cases, and in large doses, although he reported at the same time a pseudo-meningitic accident following injections amounting to 9.30 grams in one patient. —*Gaz. Méd. de Liège*, February 6.

Trephining a Suborbital Abscess.—A delicate and interesting operation is Michel's new method of operating upon a suborbital abscess where the frontal sinus is suppurating. Jurass treats it with a naso-frontal catheter, Schoeffer perforates the bone above, and Panas trephines the orbit. But Michel trephines the frontal wall of the sinus. He applies a trephining crown 5 mm. in size, at a tangent to the two sides of the angle formed by the vertical median line and the line of the two cavities. This opens a larger space and has the least disfigure-

ing results. The pus cavity is drained through the naso-frontal passage, according to Guillemin, or by Rollet's method of using the suborbital fistula. — *Province Médicale*, January 11.

Nephrotomy for Complications of Cancer of the Uterus. A writer in the *Centralblatt für Chirurgie*, January 26, questions the advisability of prolonging the life and sufferings of persons afflicted with inoperable cancer of the uterus, when the compression causes occlusion of the ureter, by operating for the latter complication. Jayle and Labbé describe three cases of this kind treated by simple nephrotomy and keeping the kidney fistula open. Patients lived afterward 19, 73 and 106 days. Their ages were from 32 to 43 years. The first died from suppuration of the kidneys; the second succumbed to cachexia. Le Dentu records a similar operation, but patient died in thirteen days. Picqué treated a patient in this way, who survived fifteen weeks. — *Ann. de Gyn.*, September, 1895.

Lupus and Syphilis Differentiated. Lupus usually develops on the face and hands but occasionally it is found on the body. One case described in the *Gazette Médicale de Liège*, Feb. 6, 1896, had two large patches each side of the spinal column, which were treated by scraping with Volkmann's curette and with Vidal's for the smaller humps, after a general and local anesthetic had been administered, and then carefully thermocauterized and dressed with iodoform and sublimated gauze. The surface healed with healthy granulations and recovery ensued. The chronic character of lupus is a guide in differentiating it from syphilis. It is not always easy to differentiate ulcer of the tongue. It can be traumatic, cancerous, tuberculous or syphilitic. The history of the case is a guide; the cancerous does not appear before 40; the tuberculous is torpid and only appears in latest stages of disease. Although there may be no other evidences of syphilis, yet it is safe to treat it as such if the above points exclude the other causes. Daily touching with a 10 per cent. solution of chromic acid (Dühring) is an efficient supplement to other treatment.

New Method of Puncturing and Opening the Pericardium.—In cutting into the pericardium care must be taken not to injure the internal breast and the heart itself. Delorme and Mignon, who have been making a study of this subject, offer the following suggestions: Tests made with sixty cadavers to determine the connection between the left edge of the pleura and the left edge of the sternum, convinced the operators that the former passes under the latter as far down as the fifth intercostal space. Below this it spreads away from it. Consequently they recommend that the opening should be made in the fifth or sixth intercostal space, and even then it is only by the greatest care that the operator does not open into the pleura, which would inoculate it with pus from the pericardium, and lead to serious trouble. The recommended method is:

1. Puncture. Insert the trocar lengthwise of the sternum opposite the fourth or fifth intercostal space. Then carry the needle flat against the posterior surface of the sternum about the depth of a centimeter. Then raise it upright and push it down and back. This punctures the pericardium alone.

2. To open the pericardium. They cut the cartilages of the fifth and sixth ribs along the sternum, then detach the pleura with the fingers, when the pericardium will be exposed to view, which can be seized with pincers and pulled out enough to puncture and open with a grooved director. These new methods obviate all the inconveniences of the old-fashioned methods.

Deodorization of Iodoform. The *Journal de Médecine* of January 19, republishes the following from the *Presse Médicale* prefacing it with the query: Why not use di iodoform? This has all the properties of simple iodoform without any odor, as Hallopeau demonstrated before the Société de Thérapie, in 1891. Jaksch observed that all the antiseptics with a specific odor possessed the property of disguising the odor of iodoform, while their own became scarcely perceptible. Thymol, naph-

thalin, tar and creolin can be used in this way, preferably the latter, in the proportion of 1 to 2 per cent. This produces a brownish powder with a mild aromatic odor. Oppler suggests pulverized coffee in a proportion of $\frac{1}{3}$ to $\frac{1}{4}$. Ten per cent. conmarin or vanillin disguises the odor of iodoform, and also acid of cinnamon in equal quantity to the iodoform. Laura Goodman observed that after a menthol pencil had been left an hour or two in a bottle of iodoform the odor had disappeared. There is a bituminous iodoform made by a secret process; and brownish mica-like scales with a metallic luster, are produced by blending tar with the iodoform to the point of deodorization. Kay made a 10 per cent. paste of tar that had no odor except that of the tar; 5 per cent. produces a powder in which the iodoform is not recognized. Negel's pills are made thus: 3 grams iodoform, 15 grams tar and 0.60 grams extract of opium for 120 pills, administered eight a day. Cantrelli mixes equal parts of iodoform, essence of menthol and essence of lavender.

Tuberculous Infection in Hospitals.—The meeting of the Académie de Médecine of January 27 was devoted to a discussion of the contagiousness of tuberculosis and the many deaths resulting from infection in hospitals. Several members consider it as contagious as diphtheria, measles or smallpox, and say it should be isolated and disinfected with the greatest care. Terrier asserted that the mortality among the internes, nurses and servants of the hospital he is connected with traceable to infection from phthisic patients, is something frightful, as he has watched its development year after year. All agreed that the present methods of treating persons affected with tuberculosis are criminally lax in regard to the general health of the community, and radical reformation is imperatively necessary.

Congenital Luxation of the Thigh and its Treatment.—It is a comparatively easy matter to diagnose this trouble, but more difficult to discover its etiology. We usually find that it is due to a lack of proportion between the head of the femur and the socket. The former is usually properly proportioned, but the socket is often too small, and also the neck. The muscles are also sometimes involved, which can be determined by noting the effect of electricity upon them. In trying to manipulate the parts into place, the resistance we encounter in working down the upper end of the femur, is due less to the pelvotrochanterian muscles than to the iliac and psoas, and also to a thick fibrous band parallel to the Bertin ligament, starting from the lower part of the capsule. Treatment should be very slow and gradual, commencing as promptly as possible after diagnosis is established. If the head can be successfully placed in the socket, a plaster cast should be applied for four months, changing it occasionally. If this fails, extension is the next treatment to be applied, continued for several weeks, when manipulation should be recommenced. If the femoral head is in place, but does not fit, surgical intervention becomes necessary to enlarge the socket. If the neck is crooked it must be reduced and kept in position until osteotomy can be performed. If the head of the femur is still held in such a way that it can not slide down into the socket, the obstacle must be cut, and the head and socket altered to fit each other. In malformations or deformities where the head of the neck are wanting, surgical intervention is strictly counterindicated. In these cases all that is possible is to teach the patient to walk, and by means of a correcting corset modify the lumbar deformity and prevent the femur from riding up, as far as this is a possibility. *Journal de Médecine*, Paris.

Leucocytes and Albumin in the Urine as Aids to Diagnosis.—Reincke and Goldberg have been experimenting to determine the number of lymph corpuscles in the urine. The former used the Thoma Zeiss apparatus after thoroughly mixing the urine with a 1 per cent. salt solution. The variations between extremes noted were from 3.73 to 26.74 per cent. The improve-

ment of a cystitis can be distinguished in this way. If there is more than 1 per cent. albumin to 100,000 leucocytes in a cubic millimeter, there is reason to suspect an accompanying nephritis. Goldberg asserts that more than 1 per cent. albumin to 50,000 pus cells indicate true renal albuminuria. He has also numbered the red blood corpuscles in hematuria and calculated the amount of blood lost. He concludes that if there are less than 1000 3000 red blood corpuscles in a cubic centimeter of urine, then the presence of albumin is proof of renal albuminuria. He also adds that if there is more than 1 per cent. albumin to 30,000 blood corpuscles in a cubic centimeter of filtered urine, then a renal albuminuria coexists with the albumin derived from the blood.—*Berl. klin. Wochens.*

Washington Notes.

WEEKLY REPORT OF THE HEALTH DEPARTMENT.—The report of the Health Officer for the week ended February 22 is as follows: Number of deaths (stillbirths not included), 118; death rate per 1,000 per annum, 22.27; death rate per 1,000 per annum, corresponding week last year, 25.76.

MEDICAL SOCIETY.—At the meeting of the society held on the 26th ultimo, Dr. Wm. Forwood, U. S. A., reported two cases of diseased liver operated upon by himself. In the first the gall bladder contained 419, and in the second 705, stones. Dr. Robbins read a paper on "Syphilis of the Vital Organs." Dr. Metzgeroll read a paper entitled "Two Hundred and Fifty Cases of Syphilis Faultily Treated by Specialists." Dr. MacKall reported a case of foreign body lodged above the soft palate.

DEATH OF DR. SMITH TOWNSHEND.—Dr. Smith Townshend, for fourteen years Health Officer of the District of Columbia, died suddenly February 25, and was buried on the 27th with Masonic honors. He was one of the most honored and respected members of the profession.

RETIREMENT OF MEDICAL DIRECTOR WALES.—Dr. Philip Skinner Wales, ex-Surgeon-General of the United States Navy, and now a medical director serving on the naval retiring board, was retired from active service on the 27th ultimo.

WASHINGTON BOARD OF TRADE.—At the special meeting of the Board of Trade held on the 25th ultimo, under the direction of its Committee on Public Health, Dr. Samuel C. Busey, its chairman, reported the following preamble and resolution, which was unanimously adopted by the Board:

WHEREAS, the city of Washington, being the capital of the United States, should be placed and kept in the best sanitary condition; and

WHEREAS, such condition can only be secured by having every habitation or habitable house connected with an ample supply of pure drinking water, and with a system of foul water and sewage disposal which will promptly remove such fluids beyond the city limits in such a manner as to absolutely prevent soil pollution; therefore, be it

Resolved, 1. That the general system of water supply from the Potomac River should be extended so as to be available for the supply of every habitable building now in the city or which may be erected within the city limits, and that this provision should be extended as far as possible to the immediately adjacent suburban districts.

2. That the general water supply should be purified by sedimentation and filtration (the first being necessary at certain times and the second at all times) before it is admitted to the mains.

3. That the system of sewerage which has been adopted should be extended *pari passu* with the system of general water supply until every habitable house can be readily connected with it.

4. With the completion and purification of the conduit system of water supply all springs, pumps and wells should be closed by such means and methods as will prove so effective that no human being can obtain drinking water from either of these sources.

5. As rapidly as possible, *pari passu* with the extension of the conduit system of water supply and system of sewerage, the owners of every habitable and inhabited house should be compelled to make satisfactory connections with such systems of water supply and sewerage, and all privy boxes,

cesspools and other methods of disposal of human excreta be effectively abolished.

6. Without adequate supply of pure water for all domestic purposes and sewer connections of habitable and inhabited houses, pollution of soil, foods and drinks and the diseases due to such pollution can not be prevented; and

WHEREAS, the enormous and constantly increasing area of marsh along the eastern border of the city is a constant menace to the health of the residents of the eastern section of the city, and especially so to the inmates of the almshouse and hospital, St. Elizabeth's Asylum and army and navy forces, officials and employees at the Marine Barracks and Navy Yard; therefore, be it

Resolved, That the reclamation of these marshes is imperatively demanded and should be accomplished without unnecessary delay.

The medical men on the committee are Drs. S. C. Busey, Geo. L. Magruder, W. W. Johnston, W. P. C. Hazen and W. S. Thompson.

Louisville Notes.

ACADEMY OF MEDICINE. At a recent meeting of this society, a symposium of papers, was presented on rheumatism. The following were the titles: "Etiology and Pathology," Dr. Carl Weidner; "Complications," Drs. Frank C. Wilson and Crittenden Joyes; "Treatment, non-medicinal," Dr. Curran Pope; "General Treatment," Dr. T. H. Baker. At the last meeting Dr. Albert Muench read an interesting report of cases. At the next meeting Mr. E. H. Mark, Superintendent of the Louisville Public Schools, and formerly Professor of Physics and Chemistry in the Louisville High School, will give a practical lecture and demonstration of the Roentgen rays, exhibiting some photographs taken in this way. The discussion will be opened by Dr. H. M. Goodman, who has done some work in this line.

DR. W. H. WHITE, Health officer, has been the recipient of many commendatory letters and resolutions from the various medical societies, and petitions, signed by medical men and laymen, are to be presented to the Mayor, requesting that Dr. White be retained in his present position.

THE REPORT OF THE HEALTH OFFICER for the past month is as follows: There was a total of 259 deaths; pneumonia caused 32, consumption 30; organic heart disease 17; cerebral meningitis 13; and there were 18 stillbirths. There were 226 deaths in the corresponding month last year; annual death rate per 1,000, 16; vaccinated, 400; diphtheria, placarded 27, of which there were 5 deaths; scarlet fever, placarded 40, with no deaths. Diseased cattle killed 128, and 277 diseased cattle condemned and sent out of the city. For the week past there were 90 deaths, pneumonia causing 13.

DR. NELL.—Dr. E. M. Nell, State Senator from Adair County, has been decided upon, by the Sinking Fund Commissioners as the warden for the Frankfort penitentiary.

STATE BOARD OF HEALTH.—This body, with a full meeting, held its session recently in this city. Several important points came up for discussion, the chief topic being the suppression of the cerebro-spinal fever in the southern portion of the State. The State Board Bacteriologist was sent to the infected county, with full power to act for the board in stamping out the epidemic.

NORTON INFIRMARY. The following report has been published, showing the charitable work done by the John N. Norton Memorial Infirmary of this city. During the year 1893 there were forty-two patients who occupied endowed beds 140 weeks and six days; seven patients occupied endowed cots, sixty-nine weeks, two days. In 1894, thirty-six patients occupied endowed beds, seventy-six weeks; six patients occupied cots fifteen weeks, three days. In 1895 twenty-seven patients occupied endowed beds one hundred and six weeks and four days; three patients occupied cots nine weeks and six days. This report was made to correct a rumor, accidental or malicious, which stated that no charity patients were received at the Norton Infirmary and that pay patients occupied endowed beds continuously.

Cincinnati Notes.

THE MORTALITY REPORT for the week ended Friday, February 21, gives: Membranous croup 1, diphtheria 1, influenza 2, measles 3, scarlet fever 1, typhoid fever 2, other zymotic diseases 3; cancer 5, phthisis pulmonalis 14, other constitutional diseases 6; apoplexy 5, bronchitis 10, convulsions 4, gastritis and gastro-enteritis 3, heart disease 5, meningitis 5, peritonitis 2, pneumonia 12, other local diseases 21; deaths from developmental diseases 14, deaths from violence 1, deaths under 1 year 26, deaths from 1 to 5 years 18; deaths from all causes 120. Annual rate per 1,000, 17.82; deaths during preceding week 148; deaths during corresponding week, 1895, 165; deaths during corresponding week, 1894, 102; deaths during corresponding week, 1893, 129.

DR. F. W. HARMON has been to Columbus before the Legislature to urge that additional appropriation be made for Longview Asylum in order to avoid the necessity of Hamilton County meeting the deficiency. His report for last year shows: Total expenses, \$145,000; number of patients, 1,023; food, light and clothing per capita, \$114. The per capita expense was \$3 lower than the average of the other Ohio institutions.

THE LAST LOT OF DRUGGISTS who were arrested by the State Food and Dairy Commissioner decided to fight their cases before juries instead of pleading guilty as heretofore, and as a result five out of nine were found not guilty.

DR. G. D. LIND, of the National University, delivered a lecture on "The Oyster and Its Relations" before the Cincinnati Society of Natural History last Tuesday evening.

DRS. SCHMIDT, RANKIN, KEARNS, WINTERMEYER AND WALLINGFORD, the district physicians of Covington, have requested the City Council to raise their salaries from \$12.50 to \$30 per month, and as an inducement offer to furnish all necessary medicines in tablet form, which they claim would result in a saving to the city of about \$150 per year.

THE NEW CATHODE RAYS were tried at the Presbyterian Hospital last week by several of the staff to locate if possible a bullet which was supposed to have lodged in the interosseous tissue of the arm of a young boy who was accidentally shot and in which the probe failed to reveal the location of the bullet. The results were unsatisfactory, the failure being partly attributed to the batteries.

AN UNUSUAL CASE of aneurysm located in the cervical vertebra was admitted to the Cincinnati Hospital this week. The patient, a young man, was admitted for treatment of a bad cough which, upon examination, proved to be the first stage of phthisis. After being treated for several days he felt much better and was walking around in the ward; one of the nurses noticed him lie down, and passing by the bed a few moments later saw he was dead. An autopsy was ordered and an aneurysm was found pressing on the spinal cord. With the exception of a slight tubercular invasion of the lungs he was in good physical condition. This is the first case of the kind ever admitted to the hospital.

THE BOARD OF MANAGERS of the Presbyterian Hospital have in contemplation the addition of an emergency surgical ward to the institution to meet the increasing demand for beds.

THE CINCINNATI TRAINING SCHOOL FOR NURSES, which formerly had the contract with the Cincinnati Hospital to supply its nurses has decided to close the portion of the institution devoted to the training of nurses for want of financial support. It will still be open, however, to a limited number of private patients.

A NUMBER of Cincinnati men are aiding in having the bill now before the Legislature passed, fixing the penalty for abortion at twenty years imprisonment instead of seven as at present. The recent Pearl Bryan case has had much to do in arousing this sentiment.

THE BOARD OF MEDICAL EXAMINERS made the report of their annual examination to the Mayor this week and it shows 204

men in perfect physical condition, 141 in need of active exercise for at least one hour each day, 50 who are only in fair condition and 16 who are totally unfit for service.

THE MEDICAL COLLEGE OF OHIO has at last formally combined with the University of Cincinnati.

AT A MEETING of the Alumni of the Cincinnati College of Pharmacy held February 24 for the purpose of having the present pure food and dairy laws amended, the following committee was appointed to draft an amendment to the laws and present it to the Legislature during its present session: Otto Rauff, Frank Freericks, Alfred De Lang, Theo. Wetterstroem and Andrew Diebold.

THE ANNUAL ELECTION of officers of the Academy of Medicine resulted as follows: President, Jos. Eichberg; First Vice-President, Robt. W. Stewart; Second Vice-President, Amelia J. Pryor; Recording Secretary, W. E. Schenck; Corresponding Secretary, A. G. Drury; Treasurer, Geo. E. Jones; Financial Secretary, S. E. Allen; Librarian, Arch. I. Carson; Trustees, John A. Murphy, N. P. Danbridge and J. T. Whittaker.

THE PUBLIC SERVICES.

Marine-Hospital Changes. Official list of changes of station, and duties of Medical Officers of the U. S. Marine-Hospital Service, for the nineteen days ended February 19, 1896.

Surgeon R. D. Murray, when relieved at Tortugas Quarantine, to proceed to Mobile, Ala., and assume command of Service, Feb. 19, 1896.

P. A. Surgeon C. T. Peckham, to proceed from San Francisco Quarantine to Port Townsend, Washington, and assume command of Service, Feb. 6, 1896.

P. A. Surgeon P. C. Kallach, when relieved at Cincinnati, Ohio, to proceed to Charleston, S. C., and assume command of Service, Feb. 6, 1896.

P. A. Surgeon L. L. Williams, when relieved at Charleston, S. C., to report at Bureau, and then to proceed to Tortugas Quarantine and assume command of station, Feb. 6, 1896.

P. A. Surgeon G. T. Vaughan, granted leave of absence for seven days, Feb. 17, 1896.

P. A. Surgeon J. O. Cobb, when relieved at Port Townsend, Washington, to proceed to Cincinnati, Ohio, and assume command of Service, Feb. 6, 1896.

P. A. Surgeon H. D. Geddings, when relieved at South Atlantic Quarantine, to report at Bureau for duty, Feb. 6, 1896.

P. A. Surgeon M. J. Rosenau, to assume command of the San Francisco Quarantine Station, Feb. 6, 1896.

Asst. Surgeon J. A. Nydegger, to proceed from Washington, D. C., to Reedy Island Quarantine for special temporary duty, Feb. 17, 1896. To report at Bureau preparatory to assuming command of South Atlantic Quarantine, Feb. 19, 1896.

RESIGNATION.

Asst. Surgeon Edgar Strayer, resignation accepted, to take effect Feb. 14, 1896.

Change of Address.

Barbat, J. Henry, from 1612 Folsom Street to 1412 Folsom Street, San Francisco, Cal.; Baird, T. M., from Hot Springs, to Forest City, Ark. Manley, T. H., from 302 W. 53rd Street to 115 W. 49th Street, New York. Nye, Geo. L., from Wythville, Va., to Hurricane, W. Va. Van Cleve, A. H., from Eddy, N. M., to Sheldon Blk., El Paso, Texas.

VOL. XXVI.

CHICAGO, ILL., MARCH 14, 1896.

No. 11.

ADDRESS.

AN ADDRESS.

Delivered before the Gynecological Society of Boston, Jan. 9, 1896.

BY JESSE F. FRISBIE, M.D.

NEWTON, MASS.

Ladies and Gentlemen:—As president, it becomes my privilege and pleasure to welcome the members of the Gynecological Society of Boston, and the assembled guests, to the celebration of the twenty-seventh anniversary of its foundation. Most heartily do I congratulate the members of the society on this auspicious occasion, and in their name do I give glad welcome to our guests.

On the evening of Jan. 22, 1869, eight medical gentlemen met at Hotel Pelham, in this city, and organized the first distinctive society for the scientific study and investigation of the diseases peculiar to females, and christened it the Gynecological Society of Boston. I say the first society of its kind for, as far as I know, it was the first gynecologic society formed in this country or Europe. At the time it was organized there was not in the medical schools a recognized department of gynecology. Whatever work was done, whatever instruction was given in this direction, was largely by obstetricians. Obstetrics and diseases of women were classed together and taught by the same professors. The following is the simple preamble: "The undersigned, desirous of advancing the study and treatment of diseases of women, hereby associate themselves together with that intent, and adopt for their government the appended constitution and by-laws." This was signed by George H. Bixby, Samuel L. Dutton, H. M. Field, Winslow Lewis, John C. Sharp, Horatio R. Storer, Levi F. Warner, William G. Wheeler.

The constitution and by-laws adopted were the simplest and conformed to the Code of Ethics: "This society recognizes the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION as binding upon its members," thus beginning its career with the expressed acceptance of the highest medical professional laws of this country.

The following gentlemen were elected officers: President, Dr. Winslow Lewis; Secretary, Dr. H. R. Storer; Treasurer, Dr. George H. Bixby; Committee on Membership, Dr. W. G. Wheeler, Dr. L. F. Warner, Dr. S. L. Dutton; Committee on Foreign Literature, Dr. J. C. Sharp, Dr. H. M. Field. And thus the Gynecological Society of Boston was organized and at once proceeded to the work for which these medical men had come together.

And now I deem it judicious and proper—a well-deserved tribute—that a few biographical words should be said here with reference to these gentlemen who have done so much for the advancement of gynecologic science.

Dr. Winslow Lewis, a graduate of Harvard and a student in Paris and London, was a trained surgeon and anatomist, a pupil of the late Dr. John C. Warren, connected by position on the consulting staffs with the Massachusetts General, the City and Carney Hospitals. He was the founder and for many years president of the Boylston Medical School, city physician of Boston, and in other respects a prominent professional man. He died in 1875.

Dr. George H. Bixby, South American by birth, educated in New England, followed by six years' professional study and practice in Europe, the latter part especially devoted to diseases of women. He was a man of fine literary and professional attainments.

Dr. Horatio R. Storer was one of the earliest and oldest students and instructors in gynecology. He was, in fact, the originator and real founder of the society. From his graduation he endeavored to bring into prominence the idea of special study and special work for the treatment of the diseases of women. He spent years of study in Europe and for a time was a special student with Sir James Simpson, of Edinburgh, and in conjunction with Sir Walter O. Priestly, edited his works. He was lecturer upon medical jurisprudence and obstetrics in the Birkshire Medical College, assistant instructor in Harvard Medical School, the first physician in America to give a complete collegiate course upon diseases of women. His connection with medical societies in this country and Europe, hospitals and State commissions are far too numerous to mention. Special honors have been conferred upon him from nearly all parts of the civilized world.

Dr. Levi F. Warner was a true-hearted, Christian physician; able, competent, skillful and always a genial companion, an honor to the profession and high manhood, respected and beloved. His honors were many and when, six years ago, he passed from the field of labor and entered into his eternal rest the world lost a great man full of honors and years, and we mourn one of our brightest and most steadfast friends. The world is better because he lived.

Dr. William G. Wheeler, a fellow student with Dr. Warner, whose kindly, genial spirit, coupled with his high professional abilities, have won for him the respect, esteem and almost veneration of all who know him. Honors have been his and it is cause for congratulation that he still abides with us.

Dr. Henry M. Field, professor in Dartmouth Medical College, one of the ablest therapeutists and most scholarly men in the medical profession—broken down through over-work—is now spending his declining years in the genial, sun-blessed climate of Southern California.

Of Dr. Samuel L. Dutton and Dr. John C. Sharp, the other two medical men among the original founders, I can only make brief mention. Their connection with this society was not long continued, and appa-

rently other professional duties prevented them from taking very active part in its work. Dr. Sharp died Sept. 22, 1890.

These were the founders of the Gynecological Society of Boston: strong, full-brained, skillful, scientific pioneers in this department of medicine and surgery, whose successes have added lasting glory and honor to the medical profession. As soon as the success of this society was an assured fact, as soon as there was demonstrated the great advantage, the need, yes, and the demand for separate and scientific instruction in this department, other gynecologic societies were organized, both local and national, in this country and Europe, and the medical colleges all over the civilized world hastened to establish professorships of gynecology. But the honor, the palm for the organization of the first society belongs to Boston and the few earnest, zealous, far-seeing and able men who founded this one. During these years—from 1869 to 1896—we have added many hundreds to our number of active, corresponding and honorary members. In this long list of names will be found nearly all the first gynecologists of two continents, men who considered it an honor to hold such membership and the society was honored by the acceptance.

The great interest which these gentlemen—representative medical men in Europe and America—continue to have in this society is manifest in their appreciative and congratulatory replies to the invitations sent for this evening. In order that this society might exert a wider influence on the general practitioner, be of greater aid and advantage, especially to those medical men who have not had opportunities for special studies in gynecologic investigation and practice, it was decided to publish its proceedings under its own authority, and Dr. Lewis, Dr. Storer, Dr. Bixby were elected editors of a monthly periodical called *The Journal of the Gynecological Society of Boston*. As a medium for the general dissemination of information pertaining to diseases of women it was a success from the beginning.

Since the organization of this society other medical men have become active members whose names bear a world-wide reputation, whose skill and remarkable successes are known and acknowledged on two continents, whose published works are standards with the foremost professional men everywhere. The founders can congratulate themselves on the fact, following its organization, influenced by its scope and work other societies were organized and gynecology bounded to the front and became a distinct and important specialty in college instruction, hospital and private practice. Well may this society take pride in its past achievements, in the grand work it has done and in the brilliant record made by its members.

With the honors and successes that have come to us during the years that are gone, we may look forward with bright anticipations to still greater triumphs in the future, to greater advances in gynecologic science, to greater aid in the comfort and cure of those suffering from disease, and posterity will gladly and freely give tribute to the fathers of this society in words of old: "Well done thou good and faithful servants."

Some of us show by the silvering hair the rapid passing years and the nearing of the time when we shall have accomplished our work.

While we labor on we may console ourselves with the thought so beautifully expressed by our dearly

beloved poet, Oliver Wendell Holmes: "Where the snowflakes fall the thickest, there nothing can freeze."

The following gentlemen have been presidents of the society: Dr. Winslow Lewis, Dr. William G. Wheeler, Dr. Henry M. Field, Dr. W. S. Brown, Dr. J. C. Irish, Dr. J. F. Frisbie, Dr. Horatio R. Storer, Dr. Henry O. Marey, Dr. H. C. White, Dr. A. P. Clarke.

ORIGINAL ARTICLES.

SOME REMARKS ON THE HISTORY OF THE GREATER EPIDEMICS OF THE PAST. AND THE MANNER OF TRANSMISSION.

Read before the Milwaukee Medical Society.

BY U. O. B. WINGATE, M.D.

PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM, AND HYGIENE, IN THE WISCONSIN COLLEGE OF PHYSICIANS AND SURGEONS, MILWAUKEE, WIS.; SECRETARY OF THE WISCONSIN STATE BOARD OF HEALTH.

It is only possible, during the few moments allotted to me at this time to refer, in the briefest possible manner, to some features of certain epidemics in the past. I shall only consider the four diseases which stand at the head of epidemics, namely, the plague, asiatic cholera, yellow fever and smallpox.

I.—THE BUBONIC PLAGUE.

This is a disease of great antiquity. The first extensive epidemic of which history has given us any definite account occurred in the sixth century, is described as "the plague of Justinian," and is said to have persisted during nearly the whole of that emperor's long reign. It probably originated in Lower Egypt in the year 542 A.D. It swept with increasing fury over Asia Minor; it also visited Constantinople with the result that for some days people died, so it is related, at the rate of 10,000 daily. For seventy years this disease raged in all parts of the then known world, and its victims were numbered by millions. In the fourteenth century it appeared under the name of the "black death" and is said to have destroyed 13,000,000 people in China, 24,000,000 in other Oriental countries, and not less than 25,000,000 people in Europe. The same disease is classed under the head of "the great plague of London" which occurred in 1665, when the total number of deaths is placed at 100,000. The same plague occurred at Marseilles and Toulon in 1720. Its last appearance in Europe was reported to be at Dalmatia and Turkey in 1840-41. The bubonic pest, however, has never ceased to exist in China, showing itself more or less frequently, and spreading from there, from time to time, to Persia, Arabia and Asiatic Russia. It is probable that for the past fifteen years it has continually existed in the southern part of China, and the recent outbreak there shows that its virulence is no less than existed formerly. According to the official reports for the six months from February to July, 1894, inclusive, in Canton, which has a population of about 1,000,000 there were 180,000 deaths. The official reports from the city of Hong-Kong up to August, 1894, showed that 2,504 deaths occurred from this disease out of a population of 200,000. It is, however, believed that as every Chinese man or woman, when seized with it, got over to the main land, if he or she possibly could, the actual number of deaths out of that population was probably much higher.

The death rate is simply enormous. Yersin places

it as high as 95 per cent. even in hospitals. In this recent outbreak the disease occurred among the Chinese principally, more especially among women and children, and among those who were the least able to resist the invasion of any disease. It was also observed that it raged worse among families living on the first floor of houses next to the ground, and that those living on the water, in many instances escaped, which leads us to believe that the condition of the soil has something to do with the spread of the disease.

From the investigations made by Kitasato and Yersin, there is no longer any doubt that the bacillus has been isolated by them and, thus far, they have been unable to observe that the bacillus has any spores. It is claimed that the bacillus enters the human body by three channels—through the respiratory and digestive tracts, and through an external wound. It seems to be a disease of poverty, and flourishes best in overcrowded localities where there is a lack of proper ventilation, personal cleanliness, and proper and sufficient diet. It is a typical infectious disease; a filth disease caused by a bacillus. There is no doubt that it has been and can be transmitted through merchandise, such as rags, and other material, that may be shipped from one place to another. Just how long the bacillus may live under certain conditions does not seem yet to have been demonstrated, but it is believed that it will live for a long period under favorable conditions. We do know, however, that it can be easily destroyed by the degree of temperature employed in disinfecting by live steam. It is probably transmitted by food, drink and air. Like cholera, it has followed the channels of commerce. In the recent outbreak it found its way from Yunnan along the southern border of Kwang-se to Pakhoi, from whence it traveled northward through the Kwang-tung province to Canton. From the latter city it was readily conveyed to Hong-Kong by persons removing while actually suffering from the disease, or during the period of incubation. It only requires about eight hours of time, by steamer, to pass between these two cities, and in the late epidemic it was quite common to have several deaths occur on the passage between these two points. According to Mr. Rocher, pigs, goats, rats and other animals, die in great numbers before man is affected, and it has been noted that a high mortality exists among these animals two or three weeks before cases of plague are noted in the human family. Just what the relationship may be in regard to this matter is a question not yet fully worked out or understood. Yersin has called attention to the results of his autopsies of animals, which showed that many dead flies were found. On examination of their bodies, he found them to contain the plague bacillus, and an inoculation of guinea pigs from such flies caused death within forty-eight hours with specific lesions of the disease. There is not much question that this disease may be carried to any part of the civilized world, and an outbreak in any locality should be watched very carefully by sanitary authorities.

II.—ASIATIC CHOLERA.

The history of epidemics of this disease, prior to the seventeenth and eighteenth centuries, is so imperfect that we can not depend very much upon it. Mention is made of it in the Sanscrit and Chinese writings; it is also spoken of by Hippocrates, Celsus, Galen and others, but we do not find a clear description of it, as existing epidemically, prior to the seventeenth century. Since then it has occurred as an

epidemic in so many localities that it would be impossible to name them all. As long ago as 1768-71, Sonnerat described an epidemic in the neighborhood of Pondicherry which destroyed 60,000 lives. In what was then known as French India in 1780-81 it also prevailed, and we also have reports of epidemics occurring in Madras from the years 1774-82. The first really famous epidemic dates from Jessora in 1817, although it has been proved that other cholera epidemics existed in India prior to this. In 1817 in Jessora, a city some forty hours ride northeast from Calcutta, there existed a patient who had been seized in the night with violent vomiting and diarrhea. A local Indian physician called on an English physician, Dr. Robert Tytler, to see this patient. He found him moribund, and thought at first that it was a case of poisoning, but when he learned that some seventeen other cases had been attacked at the same time and had quickly died, he came to different conclusions. This was a case of genuine Asiatic cholera, and so rapidly did the epidemic spread that within two months, in the city of Jessora, more than 10,000 of the inhabitants had died. During this same year the disease prevailed throughout the whole of English India, reached Calcutta in September, and caused a heavy mortality. An army encamped on the banks of the Sind lost within a short time 764 officers and European soldiers and about 8,000 Sepoys. In the first year the number of cholera victims is given as 600,000. It is possible that this number is somewhat exaggerated, as statistics under such circumstances are unreliable, and were especially so at that early age. Cholera spread over all of Bengal in 1818, and it is reported that in Benares 15,000 persons died in two months. Epidemics spread northwardly, then westwardly, then southwardly along the coast of Coromandel, and out of 18,000 men composing General Hastings' army, stationed between Bombay and Calcutta, 9,000, or 50 per cent., died in a short time. In 1820, Bengal was again severely attacked and the epidemic penetrated to Cochin China, also to Canton. In 1821 the disease passed across the mouth of the Indus and spread itself along the coast of the Persian Gulf, whence it extended into the interior of the land. It soon appeared in Bagdad and other places. It spread also towards the East, sowing everywhere the greatest destruction, especially in Borneo and Java; the latter place is said to have lost 100,000 inhabitants. In 1823, Burmah and the Empire of China, the latter especially, were severely attacked with cholera, and about this time it showed itself for the first time on Russian soil. It spread in a westerly direction and invaded the Empire of Russia. In 1823 it penetrated the very borders of Europe. In the three following years cholera made but little progress in the two threatened divisions of the earth, Europe and Africa, and toward the close of the year 1826 the hope was cherished, says Lebert, that the epidemic was near its end, but as early as the beginning of 1827 it appeared with renewed intensity in Calcutta, and here is mentioned, for the first time, that many animals also showed the influence of the disease. In 1830 its advance toward the northeast was more positive than ever before. It soon again extended on the coast of the Caspian Sea; Orenburg, which had been already reached in the last months of 1829, was again attacked, and it is related one-tenth of the whole population was seized with cholera.

There is something peculiar in the mode of trans-

mission of this disease, inasmuch as in times past it seems to have encircled the world, when it has once started, before the pandemic has ceased. While it has been said to be a water-borne disease, there are some facts which hardly coincide with this theory, for we find it has traveled over mountains and through every part of the known world, apparently independent of water courses. Early in 1831 it appeared in Mecca and raged with great violence; later it appeared in Alexandria and Cairo; the latter place is said to have lost 30,000 people by it in the first months. In Egypt the disease penetrated up the Nile to the higher regions of this country. Constantinople was also attacked within this year, and Smyrna was seized and suffered very severely from it. It occurred in the same year in various parts of Russia, and on August 30 entered Berlin, where it caused 2,500 deaths among 200,000 inhabitants. In the northern part of Germany, at this time, it was observed to affect chickens, pigeons, and in many rivers fish perished in great numbers. In October it reached England and soon spread over the islands of Great Britain. The following March it reached Paris where it raged with extraordinary intensity, destroying one forty-third of the whole population. About the middle of 1832 it crossed the Atlantic Ocean and appeared in North America at Quebec and Montreal, traveling quickly from there to New York, Philadelphia and Baltimore, and as far south as New Orleans. In 1833 it invaded the Mexican States and was very severe in Vera Cruz and Mexico. Since that time the history is familiar to nearly every one. Its home is well known to be in India, where it is constantly present and from which place, when once started, it spreads to all parts of the world before it stops. It reached this country again in 1848, appearing first at New Orleans, and again in 1853-54, extending over a considerable portion of the United States. The next great epidemic in Europe persisted from 1865 to 1874, about ten years. Europe then enjoyed a complete immunity for a period of ten years, or up to 1884. In 1883 the scourge made its appearance in Egypt, where in three or four months it occasioned a mortality of from 30,000 to 50,000 of the inhabitants. In the autumn of 1887 it made its appearance in the port of New York, but was controlled by prompt and efficient measures of isolation at the quarantine station. It again appeared at the same port in 1892, where it received like treatment. The epidemic of cholera in Europe in 1884-5, is said to have cost France 15,000 inhabitants, Spain 180,000, Austro-Hungary 4,000, Italy 50,000, Malta 500, making a total, approximately, of 250,000 inhabitants of Europe.

We know that the specific germ of cholera, as well as that of the plague, has been isolated, and the value of the discovery of the germs of these two diseases can not be over-estimated, for it enables us to take definite precautions to prevent an introduction of these diseases and to control them if introduced. But there is much to be learned concerning the habits and conditions favorable to the propagation of the germ of cholera. We believe we can control it if we can persuade the people to be liberal in their appropriations of money, which is necessary in order to take the requisite precautions. Then again, it is of the greatest importance to be enabled to control the people should an outbreak occur.

In concluding this portion of my subject, I wish to refer to the very large increase of diarrheal diseases

that has prevailed during the past year, and especially in our own State. The idea has been suggested that the great prevalence of diarrheal diseases is indicative of approaching cholera. Is it possible that such conditions, with others, may favor or invite this disease, and may such conditions not be a part of the general causation, while the germ completes the cause?

III.—YELLOW FEVER.

Haenisch says "the Antilles were probably the cradle of yellow fever." According to Hirsch, the range of the distribution of this disease over the earth's surface takes one of the lowest places among acute infectious diseases. He says further: "If we disregard its isolated appearances at different points on the western shores of Europe and its quite recent establishment as a prevalent form of sickness on the Atlantic and Pacific coasts of South America, there remain only two among the great regions of the globe to form the seat of yellow fever; on the one hand, the shores of the Gulf of Mexico, including the West Indies and part of the Atlantic coast of the United States, and on the other hand, a part of the west coast of Africa."

The earliest history of yellow fever is enveloped in obscurity. It seems to have originated either on certain islands of the West Indies, or on vessels sailing from those points to certain points on the Atlantic and Pacific coasts. The area over which it has spread, in times past, is certainly circumscribed. That the germ, if one exists, has not been demonstrated has been clearly shown by Sternberg. There is no doubt but what it is the natural offspring of regions and places characterized by the presence of putrefying organic matter under a high temperature. The persistence of yellow fever aboard ship necessarily involves the question as to its direct cause, but whatever difference of opinion may exist as to the nature of the virus of yellow fever, there can be no question as to the conditions of its existence. Decomposition of organic matter under certain climatic conditions is an essential requisite. It was formerly believed that yellow fever could only occur during certain months of the year, from April to November. It is now, however, known that it may occur during any month of the year within the area called the "yellow fever zone."

The first trustworthy account of an epidemic of yellow fever dates from the year 1635, when it prevailed on the Island of Gaudeloupe. The adjoining islands, Dominica, Martinique and Barbadoes, were invaded a number of times in the fifty years following. Since then it has occurred on the Mexican coast and the West India islands, and on the west coast of Africa. During and since the eighteenth century, yellow fever has also frequently extended up the eastern coast of North America, the highest points reached being Halifax and Quebec. It appeared in the United States in Boston in 1693; in Philadelphia in 1699; in New York in 1702; in New Haven, Conn., in 1742; in Norfolk in 1747; and first made its appearance in New Orleans, where the greater epidemics have existed, in 1796. It has never gained a permanent foothold in the United States, having always been brought from its source in the West India islands or in that locality. It is impossible to give a detailed account of all the greater epidemics from this disease. The places in the United States in which they have occurred are numerous, including Boston, New York,

New Orleans, Philadelphia, Charleston, Mobile, Pensacola, Norfolk and Baltimore. The more important epidemics occurred as follows: In 1793 in Philadelphia with 4,040 deaths, said to have equaled 10 per cent. of the population; in 1797 in Philadelphia with 1,300 deaths; in 1798 in Philadelphia, and other places (including New York), with 5,700 deaths. In 1853 the States of Florida, Alabama, Louisiana, Mississippi, Arkansas and Texas were invaded. The deaths in New Orleans, during this epidemic, are reported to have been 7,970. In 1867 it invaded Texas and Louisiana; deaths in New Orleans 3,093; in Galveston, Texas, 1,150. In 1873 the States of Florida, Alabama, Mississippi, Louisiana and Texas suffered severely, and in 1878 the most extended epidemic in the United States occurred, according to Sternberg, invading 133 towns, chiefly in Louisiana, Tennessee, Alabama and Mississippi, where there were 74,000 persons attacked, with 15,934 deaths.

It has been frequently transported to European points from its source, but has not spread extensively at those points. The fatality has varied very much in different epidemics. It is more fatal to persons who are unacclimatized than to others. Among unacclimatized adults the fatality ranges from 20 to 60 or even 80 per cent. No race is entirely exempt, but there is no doubt that negroes are decidedly less susceptible than the white race. They are less liable both to attack and to death in the event of attack. Both the attacks and deaths are more numerous among males than females. This is, no doubt, largely owing to the greater exposure of males, and to their habits, especially indulgence in alcohol.

In regard to the manner of transmission or mode of dissemination there is strong ground for the belief that it is a microbic disease, although not yet demonstrated. It can not survive cold weather, and the first one or two frosts destroys its vitality. Under certain conditions, however, it can be carried in merchandise, vessels, and especially where there is a lack of cleanliness. It is believed to be easily conveyed in old vessels that are undergoing decay. Just how this disease enters the human body is not yet known. It is certainly infectious, and the poison is claimed to be as specific as atropia or hydrocyanic acid. It can be transported from place to place in the ordinary vehicles of travel and traffic, and in the bodies or baggage of men and women. It seems to take root, however, in the locality, in the soil as it were, and to be contracted from the environment of the patient rather than from the patient himself; the locality seems to remain infected after the patient has been removed, for weeks and even months. There is a very important circumstance connected with the transmission of this disease which, I believe, should receive very careful attention from all members of the medical profession. It is a condition which exists as a warning in other diseases, as has been referred to under the head of cholera. It was first mentioned, so far as I know, in the Surgeon-General's report of the Navy Department for 1873-74, by Dr. Joseph Wilson, Medical Director of the United States Navy, under the head of "An Interesting Epidemic." He says: "There is a variety of yellow fever poisoning which seems not to be generally understood; at any rate, not generally insisted on. I allude to the numerous cases of light febrile disease which precede the development of the fully formed fatal cases of yellow fever, usually noticed in the first cases of an epidemic. Every writer on epidemic

cholera tells us of the numerous cases of diarrhea preceding the epidemic, but no one describes these numerous cases of slight febrile disease, which are the harbingers of the yellow fever epidemic." He then goes on to show that for some time before an outbreak of yellow fever they had a large number of these febrile conditions—some diagnosed as mild typhoid, some as simple fever, etc., followed by an epidemic of yellow fever. An interesting feature connected with epidemics of this disease, as well as others, is the commercial relation, and the difficulty that sanitarians have in impressing upon the people the importance, not only from the standpoint of life saving, but from a commercial standpoint, of controlling these outbreaks. This has been well illustrated by Dr. Samuel Chopin, of Louisiana, in describing the epidemic of yellow fever that occurred in this country in 1878. It appears that an estimate of the total loss to our country from this epidemic was made by Mr. A. B. Farquhar in a letter to Surgeon-General Woodworth, in which he places the cost at \$175,000,000. In New Orleans alone there were estimated 25,000 cases with 4,500 deaths, and the cost to that city, based upon a moderate estimate, was \$12,072,500. It is also shown that the city of New Orleans, by its commercial interests with the tropical ports, from which this disease was brought, amount to about \$1,500,000 per year, while the loss in one year by the presence of yellow fever is estimated at over \$12,000,000. Dr. Chopin, referring to the quarantine system, which is impossible to make perfect on account of the commercial interests, very wisely says: "No conditional quarantine can ever be made effective, because first, of the laxity with which laws are unfortunately executed in this country, and secondly, because of the cupidity of the commercial men having large interests at stake, who will always move heaven and earth to evade successfully all quarantine laws and regulations." Until people can be educated up to the point of recognizing the importance of these sanitary measures, we can never expect to be able to control epidemics and they will occur from time to time, for it seems to be a law of nature that people must learn by experience alone.

IV.—SMALLPOX.

It hardly seems necessary for me to refer to this subject, because I take it for granted that all present have learned the lesson of experience that I have just quoted. This is another disease, the essence of which is unknown to us, as you all know. We do have, fortunately, a means of prevention, which is not provided for positively in the diseases that I have just mentioned, that of vaccination. It would be impossible, in a few words, to even scan the history of smallpox. The earliest records of its existence are to be found in Hindoostan and China very many years before the Christian era. It has invaded all parts of the world from the earliest history, and at times the havoc caused by its ravages has been something appalling. One of the earliest writers was the Arabian, Ahron, who practiced in Alexandria in the time of Emperor Heraclius, 610 A. D., but for what is known of these writings, and others, we are probably indebted to Rhazes, physician to the hospital at Bagdad, who died about 923 or 930 A. D. He was the first to distinguish smallpox from measles. Epidemics from this disease are too numerous to mention. The more severe, perhaps, occurred in Iceland, the records of which are to be found in those of the Danish gov-

ernment: the worst epidemic of all occurred in 1707; among a population of somewhat over 50,000 it carried off 18,000. In Ireland where the lamp of learning burned all through the Dark Ages, we find that this disease raged to a great extent, and a very interesting chapter might be written concerning this if time allowed. Emerging from the Dark Ages, Vidus Vidius, 1550, incidentally refers to it as attacking all persons in the course of their lives, and Mercurialis, born in 1530, holds that almost every person must have it once. Many others at this time used similar language, and it seemed to be the general impression that every person born into the world was liable to, and most probably would at some time, have smallpox. Sir Gilbert Blane is credited with the statement that "it had destroyed a hundred for every one that had perished by the plague." George Bell, of Edinburgh, in 1802, wrote that smallpox was one of the most severe and dangerous diseases to which mankind is subject.

The full power of the disease, however, can only be seen as we learn its ravages in the New World, among unprotected populations. This began in 1507 in the West Indies, where it was so disastrous that whole tribes were exterminated; in Mexico, it is related, it even surpassed the cruelties of conquests, suddenly smiting down 3,500,000 of the population and leaving none to bury them. In Brazil, in 1563, it extirpated whole races of men. At about the same period, in a single province in Quito, it is related, it destroyed upward of 100,000 Indians. In Russia, according to the calculation of Dr. Alexander Creighton, physician to the Emperor in 1812, every seventh child died annually of the smallpox; and Colon set down the deaths in France as from 60,000 to 72,000 annually. This was before vaccination. The periodicity which existed in the pre-Jennerian times is interesting as showing that an epidemic of the disease caused an immunity among those attacked who were fortunate enough to live, for a certain period of time, and there is a relationship between this thought and vaccination as practiced at the present day. This periodicity differed in different localities. The immunity seemed to be exhausted sooner in some places than in others, and may this not be true in regard to vaccination? Smallpox first made its appearance in the United States in Boston in 1649, and from then to 1792, about one year in twelve, it was epidemic, while in Vienna from 1742 to 1759 it was epidemic about every fourth year. The enormous mortality from the different epidemics in this country are too familiar to you all for me to quote, and the mode of transmission is also well known. The great prophylactic power of vaccination in smallpox has been so thoroughly demonstrated in our present outbreak, that it does not seem possible that the opponents of vaccination have a single thread to hang on. For a time being, after the disease exists, with the large amount of vaccination that has been done, smallpox will decline until the immunity is lost by time and the future generation comes up unprotected, then we will have a repetition of the disease. To prevent a prevalence of smallpox is a work difficult to perform, for as I stated before, the great masses of the people will only learn by experience. We are, however, very much better off than our forefathers in respect to knowledge pertaining to the greater epidemics. We now know some of the potent factors which cause certain diseases, that are, or may be classed as epidemic. While

the people are slow to realize the invaluable scientific discoveries that have been made concerning epidemic diseases within the past two or three decades, the more intelligent portion is beginning to understand more and more their value, and the medical profession may well feel encouraged with the progress made.

THOUGHTS ON TYPHOID FEVER; ITS ETIOLOGY, PATHOLOGY, ABORTION AND TREATMENT.

BY W. L. SCHENCK, A.M., M.D.

NEWCASTLE, COLO.

Prior to the dark ages we find little to indicate that typhoid fever was diagnosed as a distinct form of disease. When the mind of man awoke from the sleep of centuries a new impulse was given to all departments of science, and through the investigations of Spigelius, Sydenham, Huxham, Trousseau, Stoll, Petit, Peyer, Andral, Louis, Chomel, Bretonni and a host of others, we have our knowledge of typhoid or enteric fever, as a specific zymotic disease. Until within a very recent period the consensus of opinion has been that it could not be aborted, but must run a course, and whether only communicated from pre-existing cases or occurring spontaneously, are still mooted questions. Virchow says, wherever we find a cell there must have been a cell—it is a concise statement of an almost universal belief, applicable to all forms of life since the monad, the microscopic atom of protoplasm that Infinite Wisdom unnumbered ages ago placed on earth, endowed with evolutionary force, developed on and on and up through creeping things and bird and beast, to man. Without the intervention of the ages the varied cells of our bodies have been proliferated and differentiated from a microscopic mass of protoplasm, an embryonic cell, into the cells that constitute our bodies, each cell having a life of its own, and subject to the universal law, "each after its kind."

Whether the author of the earliest record of creation, made by man, sought to convey the impression that the Creator "formed man of the dust of the ground," with all his organs and their myriad cells in place, and "breathed into his nostrils the breath of life," or that when there had been evolved from the progressive monad a sufficient number of cells in the gray matter of the brain through which to correlate impressions borne to them through the senses, he

breathed into him a spiritual life and he became a living soul; in him we find differentiation completed. No new form of life, within or about us, has since appeared on earth: all the seemingly new forms, whether occurring as monstrosities or diseased cells, are only pathologic diversions. Stich in discussing the etiology of typhoid fever advanced the belief that every one carried in the intestines material susceptible of putrid intoxication, requiring only favoring conditions for the production of sepsis and typhoid fever. Peter came to a similar conclusion, believing this material was not simply foreign matter within the alimentary canal, but waste products of the organism, capable under lowered vital action of auto-intoxication. Both believed in the spontaneity of the disease, but that it originated in septic matter in the intestine. Later authorities have demonstrated the bacillus typhosus or the typho-abdominalis bacillus, the Eberth-Graffy bacillus, and Koch, Eberth, Graffy, Chautamese, and a host of investigators following in their pathway, believe typhoid fever, and perhaps all disease, the result of microscopic entities foreign to the organism, and hence its occurrence *de novo* impossible.

However life's varied forms may have been differentiated, we know that from the granule of protoplasm within the embryonic cell have been differentiated cells that differ as widely in function and form and chemic constitution as the micrococci, or even the higher forms of life, and that the toxins of their ptomaines are as varied and as virulent as a foregone conclusion. When retained within the organism may we not rationally conclude they are as capable of producing varied forms of disease as the ptomaines and toxins of the so-called pathogenic germs? Those who defend the germ theory of disease beg the whole question when they assume a lowered vitality, with the retained ptomaines of tissue cells, as a necessary precedent to germicidal activity. When natural zymosis is normal pathogenic germs are not present, or if present harmless. It is only when the devitalized cell ptomaines are permitted to accumulate within the tissues that they appear in vast numbers, and their character is determined by the chemic elements of the cell ptomaines on which they feed. While the bacteriologist tells us the ptomaines of bacilli, bacteria and micrococci contain the toxins that produce disease, what of the leucomaine and the toxin of the dead tissue cells that have failed of return to harmless elements, through defective vital action? We may breathe the purest air, drink the purest water, eat the most wholesome food, with every environment perfect, but the changes incident to all vital action involve the death of cells, and in every dead cell lies a hidden poison. If not returned to harmless elements and eliminated from the body they are ptomaines, leucomaines and may become toxins, the poisons varying in character with the chemic constituents of the cells from which they spring. If, however, as in health, metabolic and katabolic changes are normal, through natural zymosis they are returned to oxidizable, harmless forms and borne from the body through its excretories, without the generation of disease. As disturbed vital action is capable of producing all the toxins attributed to pathogenic germs, never present in force without such disturbed action, and as germicides can never be given of sufficient strength to destroy these germs without first destroying the body in which they reside, while antiseptics and disinfectants may prevent or arrest the processes that make cell ptomaines toxins,

why go "around Robin Hood's barn" for causation? If caused by toxins from the etoma of dead tissue cells retained in the body, which we may rationally expect will produce like disease wherever implanted, we have a rational theory of disease and can readily understand how it may be both spontaneous and contagious, why antiseptics and disinfectants of less than germicidal force may prevent or arrest its action, and why it does not harm those in robust health, and if there is any virtue in serotherapy and antitoxins herein lies the key. The toxins of the ptomaines, not of vegetable germs, but of dead cells of special types, undergoing a specific form of sepsis, can probably be modified by treatment so that they will produce a modified form of the specific disease they represent, and protect against future attacks as vaccine protects against variola. However the poison of typhoid fever is generated, its wide diffusion, its preference for the older and more advanced civilizations, and for early manhood, when the dangers of infancy have passed and active life with its duties and pleasures is at hand, its grave character and often fatal issue makes its consideration and the possibility of its abortion, or arrest, of great importance to the profession and to humanity. It is universally recognized as a filth disease, usually water-borne, caused by a specific poison communicated through the alimentary canal by contaminating excrementitious matter from that canal. Authorities differ as to the precise nature of the poison, but all agree that it may be rendered inert outside the body, and if without why not within? If a pathogenic germ whose vitality can not be destroyed within, without destroying the vitality of the body in which it is found, we can readily understand why not. The fact that it can be destroyed would indicate that the germ is not its cause.

Water is the medium through which the poison is usually conveyed to the alimentary canal. If caused by germs they must have been borne to the privy pit, or other source of contamination, from preëxisting cases. While the disease may often be traced to other cases every physician of large experience has had cases that, search where he would, defied all effort to trace their pedigree. They had no line of descent. By way of illustration take an extract from the memorandum of an endemic, confined to a single home, to which I shall refer again. Oct. 3, 1857, was called to see N. M., aged 10 years. She is one of a large, intelligent, cleanly and well-to-do family, living near the top of the northern slope of the divide of the two Miami Rivers, three miles south of Franklin, Ohio. She had not been from home, and no strangers had visited the house. No case of typhoid fever existed within a circuit of many miles, and no case had ever before occurred on the farm. A few days later two other members of the family were stricken with the disease. All the cases were typical typhoid fever and ran long and doubtful courses. An investigation showed that the water used by the family bubbled up clear and sparkling, in an open, well-walled cellar, and after perambulating a milk-house danced away, in a bright stream, down the hillside. The privy vault was found an hundred yards from the house, but higher up the hill. It had been there for a generation, the farm having been opened in the early settlement of the country, and the whole family were born in the house. As no other possible source of the disease could be discovered the presumption was that some of the accumulating contents of the vault had under-

gone a specific change, and found their way to the underground stream that fed the spring. In a well-developed case of typhoid fever diagnosis is not difficult. The tenderness in the right iliac fossa, consequent upon inflammation and ulceration of the solitary and agminated glands of the ileum, with a gurgling sound upon pressure, the rose-colored eruption, the fever without any distinct remission, the morning and evening temperature varying only a degree or two, the listless expression and tendency to stupor, the hemorrhages, especially epistaxis, and as the disease progresses the dusky complexion, the dry tongue with its brown coat, the accumulating sordes, the tympanitic bowels, with the constant tendency to complications, are sufficiently characteristic. It is in the earlier stages that diagnosis is difficult in a disease whose onset is so varied, and yet an early diagnosis is of the greatest importance. Though the invasion is usually so gradual that the patient does not know for a time whether he is sick or well, and in "walking" cases keeps about until suddenly taken down with perforation, it is not always thus. Sometimes the attack comes on suddenly with a chill, at others, as an acute catarrh. In other cases during the inchoative stage there is a diarrheal action, much like that produced by physic. A special susceptibility to the action of cathartics is always present. There is generally languor, listlessness, headache, and a tendency to epistaxis, likewise a general hebetude and an inclination to sleep is apparent; not infrequently there is insomnia and restlessness. An early and accurate diagnosis is important, for if we do not see or recognize the disease until there is ulceration of Peyer's patches we can not abort an ulcer, though we may yet modify or shorten the course of the disease. Whenever typhoid fever is endemic, especially when it is going through a family, as it often does, any suspicious cases should be subjected to preventive treatment. It may be laid down as a rule in any markedly contagious disease, as variola, if we err, it should be in the interest of society. So in the early stage of typhoid fever, if err we must, it should be in the interest of the patient. Wherever a case of typhoid fever is found every precaution should be used to prevent a second case. Whatever the specific poison it is generally communicated from and through the alimentary canal, water being the usual medium of communication. In all centers of population the privy pits that honey-comb the soil contaminate the city wells, whose water is the prolific source of the disease. If such water must be used for potable purposes it should always be boiled. All discharges from typhoid fever patients should be received in a vessel containing a saturated solution of crude sulphate of iron, the privy contents being saturated with the same. In every suspicious case occurring in the family where a case exists, or in the immediate neighborhood, the decks should be cleared for action and the patient put under treatment. Professor Chambers, of St. Mary's Hospital, London, a most reliable observer and attractive writer, in his lectures delivered 1861-2 says: "At an early stage, even after the virus has begun to act upon the system, the fever may be stayed by emptying the stomach. . . . Those who have watched my practice will have seen the fever cut short and convalescence entered upon immediately." Referring again to my notes of the cases in the family of M., October, 1857, I find, in addition to the three well-developed cases, three other members of the family had the pro-

dromic symptoms of the disease. To each was given a mild catharto-emetic, until free emesis. This was followed by tinct. ferri chlor. in drachm doses every six hours, rest and a mild diet. In a few days all symptoms of the disease had disappeared. We can not prove a negative, or that what does not happen would have happened. But when in a swamp region we have the premonitory symptoms of periodic fever who doubts that the disease may be aborted with full doses of sulph. quinin, or other antiperiodic, or the premonitory symptoms prevented by donning dry flannel underclothing when the chill of night comes on, and sleeping between woolen blankets? Since the above date the same experience has been so often repeated that its abortive action can not be questioned.

Dr. Woodbridge, of Youngstown, Ohio, says in the JOURNAL, April 14, 1894, that with a "eucalyptol-guaiacol mixture" he can "abort every case and save every life." While we know that many cases of typhoid fever may be aborted, we do not claim that every case can be aborted and every life saved. If not called until there is lesion in the glands of the ileum, and where there is not only tissue death in these glands, but the whole system is saturated with a poison that lowers vitality and vital resistance, we have the fully developed disease, and there can be no abortion. It must have its course. Into the parched mouth there comes no secretion from the salivary glands to digest amylaceous foods, which if digested could not enter the capillaries through the dry and thickened mucus overlying them, and the tongue and fauces typify the stomach, where no pepsin will be found to digest nitrogenous foods, while along the whole alimentary tract there is an atonic irritability that resents all ordinary attempts to provide material for repair. The glands of the outer coating of the body are as dead or dormant as those along the alimentary canal, the sebaceous cease to yield the unguents that keep the skin soft and pliable, and the sudorific, whose excretion helps to regulate both the temperature and the circulation, ceasing to act, the surface is excessively dry and hot. The hemoglobin, escaping from the poisoned cells, is found in the urine and feces, while decompositions have rendered the blood suddenly alkaline, and in all the structures of the body katabolism is in excess of metabolism; the whole organism is being destroyed by an unintermitting fire, not the heat produced by physiologic activity, but pathologic heat, caused by dead tissues returning through chemie decomposition to original elements, heat like that occasionally observed after death. All the great emunctories are sleeping at their posts, because the poisoned brain can not generate the force necessary to their functional activity, though their action is sadly needed for the removal of waste products. Let us supplement the arrested action of the sebaceous glands with frequent inunctions of cocoa butter, medicated, if you wish, with antiseptics; moisten the dry, harsh skin by frequent sponging with water or water and acetic acid, of such temperature as is most agreeable to the patient, and thus stimulate activity in the sebaceous and sudorific glands, and invite the circulation to the capillaries of the periphery. Do not seek to overcome the excessive heat by depressing the nerve centers with such sedatives as the coal-tar products. Vitality is already nearly *nil*. The heat is not disease, but only a danger signal, though beyond a certain undetermined degree it may destroy life. Here it is a necessary sign of excessive destruction

and decomposition. While you administer comfort and avoid danger by keeping it within due bounds, do not attempt to control it with depressants. Having given due attention to the surface of the body look a little farther. The functions of the digestive tract are arrested. There is loss of appetite, and if food is taken, it produces nausea or vomiting, flatulence and diarrhea, and yet the excessive disintegration of the tissues demands food for repair. Not only are the tissues in which are the stored force of the organism being rapidly destroyed, but as well the nitrogenous tissues, and material for their replacement must be supplied. Solid foods can not be digested, and if not ejected cause a putrefactive diarrhea and aggravate the glandular lesions. The beef extracts on the druggists' shelves are usually frauds. Eggs, however prepared, are liable to decompose and generate sulphuretted hydrogen and other injurious gases. There is no salivary secretion to digest amylaceous foods. Milk, almost always accessible and supplied by nature to the feeblest digestive organs of all mammals, contains not only all the elements of nutrition, but given hot, to stimulate the alimentary tract, and by sips, to prevent the formation of solid curds, is not only generally acceptable to the patient but the little waste it produces leaves the small intestines practically at rest, exercising upon them a soothing influence. So marked are its benefits that good authorities have advocated a "milk treatment." As a diet in typhoid fever milk, properly administered, is the *sine qua non*. I remember very well one typhoid patient, a previously plump and healthy girl of 16 summers, who lived for four weeks on milk, and to all questions of diet gave the unvarying reply, "Milk is good enough for me," and convalesced with scarcely the loss of a pound in weight. Milk should be given as above, in such quantities as can be digested and appropriated, every two hours, giving, if possible, at least three quarts in twenty-four hours. To supplement the oft-times absent lactic acid of the stomach, it should be preceded by a few drops of the ever reliable antiseptic, dilute hydrocyanic acid, which may be diluted, sweetened and flavored to suit the taste. If you would shorten typhoid fever and secure perfect convalescence, the first great necessity is a diet that will secure repair, and the second is like unto it, the prevention of all effort, mental or physical, that tends to exhaustion. After these essential directions we look a little farther and we find the typhoid poison is being carried to all the tissues of the body. There is a lowered vitality, lessened power of resistance and greatly increased interstitial destruction. The red corpuscles are diminished in number, many of them being "melanosed," shriveled, serrated and marked with black spots, while their hemoglobin is being discharged into the serum, coloring it and giving to the skin its dusky hue. The various cells of the body nourished by this poisoned blood suffer, the effect being especially marked in the nervous system, at first by a general aching, sometimes by neuralgic explosions, by chilliness and an increasing and deepening torpor, a general interruption of the generation and dissemination of vital force, especially marked in the cells of the cortex by failure to note and correlate impressions, and by a low muttering delirium.

As far as the absorbents and exosmosis are capable of action they carry the excessive waste to the already gravely poisoned circulation. The dead cells not fully returned to original elements are cellular ptomaines and through decomposition cause a super-

alkalinity of the vital current. The torpid condition of the great eliminators, kidneys, liver and skin, permit this alkalinity to continue and increase. Yet this grave condition is not beyond our reach, and we must not stand idly by until nature removes it or life succumbs. By the free use of hydrochloric acid and hydrochlorate of iron we can supply the deficiency of salts, neutralize the alkaline blood, arrest nutritive decomposition and render the excretions aseptic. It may be given as a grateful lemonade or mineral water, and given *ad libitum*. When it can not be absorbed we have ever at hand the modern invention, the hypodermic syringe, with which we may both nourish and medicate. The use of mineral acids in "putrid" fevers is older than the days of Boerhave, Van Sweiten and Sydenham, and they can not be driven from the field by the high-sounding products of modern pharmacists. Have alcohols any power to shorten the fever, or to help us to a safe haven? Good men answer the question differently. We think they have, but not as ordinarily given, for stimulation or nutrition, or because we are at our "wits' end," and do not know what else to prescribe. In all cases of typhoid fever destructive is in excess of constructive metamorphosis; alcohol may hold destructive metamorphosis while we build up with nutrients. When there is great nervous depression, and exhaustion is increased by its felt sense, when the tongue is tremulous and the hands shake with the slightest movement, when the pulse is sharp, weak and unequal, when there is low, muttering delirium, you may with an alcoholic anesthetic give relief. The best form is sour catawba, if the stomach is irritable, sparkling catawba. The salts in the wine stimulate the kidneys while it gently soothes the nervous system. The stronger alcohols increase the injury, already sufficiently grave, of the typhoid poison. The catawba, if pure, may be taken *ad libitum*. Galen's free commendation of alcohols in every form and in every case, has done much harm. Be sure you understand the therapeutic action of alcohols and prescribe them with intelligent purpose. Everyone who has tried it will agree with Dr. Geo. B. Wood, who says in his "Practice of Medicine," vol. I, p. 329, "I will repeat that the oil of turpentine may be used, with good hope of benefit, in any case of enteric fever in the advanced stage with a dry tongue." It should be made into a pleasant emulsion. Where there is local stasis, hastening, as it is prone to do, to a low grade of inflammation, molecular action should be aroused by hot fomentations and cups, wet or dry, as the case indicates. In all stages of the disease the patient should drink freely of muriatic acid lemonade, or a mineral water made of muriated tincture of iron, and the whole family where the disease exists should make free use of the same drink. Quite recently I have had, by accident, two instructive cases, the patients not understanding or heeding directions. October 1, called to see Dominic Roletta. Found he had had continuous fever for a week. Tongue dry, dark and heavily coated, tenderness and gurgling in the ileo-cecal region, diarrhea, pulse 95 and temperature 101 F. Among other things prescribed tinct. ferri chloridi 3iij, thirty drops every six hours. October 2 the patient had taken during the night all the tincture of iron. The tongue was moist and clean and the patient free from fever, which did not return. November 9, saw Mrs. Zangalina, aged 20, a primipara of two weeks. Found her in a filthy bed in a small, mud-covered Italian hovel,

with every surrounding unsanitary, temperature 105 degrees, pulse 150, skin mottled, abdomen tender, etc. Among other prescriptions was two ounces of dilute muriatic acid and chlorinated tincture of iron, equal parts, with directions to add enough to a glass of water to make a pleasant drink. It was all taken before my visit next morning, and *post hoc* or *propter hoc*, there was an arrest of all grave symptoms and a speedy return to health. If administered in sufficiently full doses we have in hydrochloric acid and the chlorinated tincture of iron abortifacients and curatives as positive in their action upon several of the zymotic diseases than the sulphate of quinia in remittents.

TYPHOID FEVER TREATED BY THE WOODBRIDGE METHOD.

Report of Eighteen Cases of Typhoid Fever treated by the Woodbridge Method at the Worcester, Mass., City Hospital without a death.

BY WESLEY DAVIS, M.D.

WORCESTER, MASS.

During my service from Oct. 1, 1895 to Jan. 1, 1896, there were admitted eighteen cases of typhoid fever all of which were treated by the Woodbridge method, only that the tablets were given in double doses, two every half hour in place of one every fifteen minutes. Of these cases four had intestinal hemorrhage, none commencing later than the fourth day of treatment; we had very little tympanites; no sordes, tongue rarely found dry and then only for a short time, practically no delirium. Three cases had relapse, one a slight recrudescence of four or five days, the other two had an elevation of 2 or 3 degrees and it was ten to fourteen days before the temperature reached normal again; no cause could be discovered. Two or three were nauseated by the treatment and it was suspended for a few hours and subnitrate of bismuth given, when the treatment was resumed and persisted in, not even hemorrhage being considered a contra-indication.

Several had stomatitis to such an extent that the tablets were suspended and guaiacol carb. given in from 3 to 5 gr. doses alternately with the capsules, and the bowels were kept open with 1-20 gr. of podophyllin given with each dose of medicine *i.e.*, every hour and a half or small doses of magnesia sulph. or both as seemed necessary.

One case came in with a septic hand which ultimately required amputation, but fortunately for the diagnosis he had an intestinal hemorrhage of half a pint the second day after admission. Another after several hemorrhages had a chill and temperature of 106 degrees on two consecutive days, after which no local complication being discoverable it yielded to quinin; another had a sharp attack of local peritonitis, probably nature's method of preventing perforation. There was one case of parotitis, also one of double pleurisy with slight effusion developing after ten days when the temperature was nearly normal. We had the reputation of having *mild* typhoid fever at the City Hospital during the fall. When we consider that it is mainly a charitable institution and that the city as a whole presented the usual death rate from the fever, I am compelled to think that the treatment was in a measure, at least, responsible for the mild form assumed and *no deaths*. With the same number of cases during the corresponding period of 1894 we had four deaths under the regular treatment. No typhoid case was refused admission if we could make room for it, as we were anxious to give the treatment a

thorough trial. In strict justice I wish to say that one case in a state of delirium such that it could not be longer cared for at home, was sent to the hospital after my visit one day and died before my arrival the next day, being in the hospital fifteen hours. I have not included this case but refer to it that there may not seem to be a discrepancy when the hospital report shows one death from typhoid fever during the period. The house officer says this was the only case this season where he has seen the characteristic sordes upon the teeth. The regular treatment by sponge baths, usually cold, when the temperature rose to 102.5 or 103 degrees was faithfully pursued and turpentine stupes, opiates, quinin, strychnia and stimulants when indicated were not omitted. The diet in all cases was liquid at first. Milk, lime water and milk, beef tea, beef juice and broths of various kinds in regular quantities and at stated intervals. Stale bread or toast made from it was given, whenever desired by the patient regardless of temperature, if the tongue was moist and tolerably clean; if this was eaten with a relish and did no harm it was allowed more freely and soon followed by custards, dropped egg, egg on toast, etc. *if desired*, and in a few days tender boiled chicken, baked potatoes and the like. During the treatment the stools smell quite strongly of the medicine, which would appear to show that they can get to the site of disease in the small intestines. This antiseptic treatment seems to prevent decomposition and the formation of gas whatever diet may be given and the convalescence is more rapid in consequence of the extra amount of nourishment tolerated and assimilated.

I learn from the board of health, where all cases of fever are required to be reported, that during the three months there were 69 cases reported, from which, if we deduct the 18 at the hospital, we have 51 cases cared for by the various methods and means that a city of a hundred thousand inhabitants affords, with a mortality of 12, a death rate of 23½ per cent. outside the hospital.

I wish to add that I have treated by this method seven cases in private practice without a death, and some have seemed to show that it can be aborted.

FIBROID TUMORS OF THE UTERUS. MEDICAL TREATMENT—GENERAL CONSIDERATIONS.

BY FRANKLIN H. MARTIN, M.D.

PROFESSOR OF GYNECOLOGY POST-GRADUATE MEDICAL SCHOOL OF CHICAGO; SURGEON TO WOMAN'S HOSPITAL.

In the consideration of the histology, growth, anatomy, varieties and symptomatology of fibroids of the uterus one is irresistibly drawn to the conclusion that each one of these growths is a law unto itself. Such is certainly the case when we come to the consideration of treatment.

A fibroid tumor is a benign growth. The principal symptoms arising from it are due to the effect of its presence upon organs associated with it or in close proximity to it rather than from any inherent qualities. From its slowness, in the majority of instances, to produce serious symptoms, and the rarity of a fatal termination as a direct result of it, patients are with difficulty aroused, early in the history of the disease, to adopt radical measures for relief. Hence innumerable symptomatic remedies have arisen, each for a brief time having enjoyed the reputation of specifics, only to sink into their true positions as soon as the light of

experience had shown upon them. The simple enumeration of a list of these remedies would fill a long chapter.

The remedies for fibroid of the uterus which merit attention must be considered under three principal heads:

1. Medical treatment.
2. Electrical treatment.
3. Surgical treatment.

To indicate when each of the above methods of treatment could be employed with the greatest advantage to the exclusion of the other, how or when two or more could be combined to greatest advantage would be a task which would necessitate the careful analysis of a large number of fibroid cases, together with all the peculiarities of the growths with their surroundings, the temperament and the physical condition of each particular patient possessing the tumor. The most that can be attempted is to describe the various remedies; the exact physiologic or mechanical effects of each; the manner of administering drugs; the chemic, mechanical and physical effects of electricity, with a comprehensive description of the details of application; the many operative procedures including the rationale of each with a minute technical description of those which merit attention; and finally to show wherever each remedy is especially adapted to counteract some specific condition or symptom of a fibroid uterus.

I will therefore consider each grand division of treatment in detail trusting to the diagnostician to apply the remedies as the indications in each particular case may dictate.

MEDICAL TREATMENT.

The medical treatment of fibroids of the uterus has played an important part in the symptomatic relief and the prolongation of life of those afflicted with this dread condition. For convenience its therapeutics may be divided into general tonics, alteratives, sedatives, astringents and special uterine tonics.

General Tonics.—Rapid growth of a fibroid tumor and a condition of general good health in a patient seldom exist together. So true is this, that I have learned to assure patients laboring under this disease that their tumors will not increase in size rapidly if they can by some means keep themselves in a condition of natural tonicity. While undoubtedly the cause, frequently, of the general lack of tone is the rapidly growing tumor, I believe its growth may be retarded by adopting means to counteract its effect upon the patient. While the tumor with its accompanying pain and loss of blood, and rapid growth must impair general health, that impaired tone of necessity leaves the patient with still less resistance to withstand the onward march of the disease. In other words the results of the rapid growth of the tumor does in turn become one of its aids to still more rapid destruction. Therefore fibroid-tumor patients should be abundantly nourished. The loss of blood should be met by an abundant supply of wholesome substantial food. Bitter tonics such as quassia, calumbo, nuxvomica and cinchona should be administered to increase the appetite. Iron should be administered in a form to be readily assimilated in order to improve the blood. The patient should be urged to drink milk and cream between the regular meals. Prepared foods both of the nitrogenous and farinaceous order should be employed to reinforce the ordinary diet.

Predigested foods may be found of service if the digestive organs fail to stand the strain of over feeding.

As nerve tonics the compound syrup of the hypophosphites with small doses of quinin, strichnia and iron are often of great service. Strychnia in gradually increased doses until the patient takes 1-10 of a grain four times a day, I consider of great value as a tonic in these cases. The dose should begin at 1-40 or 1-60 and be increased gradually, being careful to avoid unpleasant constitutional symptoms. This tones the bowels, acts as a vaso-constrictor tonic everywhere, and I believe acts as a direct tonic to the muscular structure of the uterus itself, while it undoubtedly acts as a vaso-constrictor to the uterus and tumor. As a direct bowel stimulant and laxative aloin with strychnia and hyoscyamus has few equals. Cascara sagrada may take the place of the above as an alternative laxative. General stimulating baths often prove beneficial tonics to fibroid patients. Sea salt baths, warm or cold with judicious rubbing to establish reaction, are often recommended. Chlorid of sodium baths may be employed in lieu of the sea salt baths.

Hot water as a local tonic, employed as a vaginal douche, frequently relieves excessive congestion of the uterus. To accomplish this object the water must exceed a temperature of 115 F., the patient should use at least two gallons at a time and should employ it while in the recumbent position on the back. Chlorid of sodium as an antiseptic and tonic may be dissolved in the water—3 to the pint. Or to get the advantage of an astringent the same amount of powdered alum will prove of advantage. The water must be hot. Tepid water will favor hemorrhage.

Change of air from the sea shore to the mountains (not too high an altitude) or from the mountains to the sea shore often improves health and retards the growth of these mysterious tumors. An ocean or a European trip will often bring a remarkable change for the better in these unfortunate cases. Even a slight move which only involves a change of routine, or surrounding the patient with a pleasant change of companions will draw them away from themselves and occasionally give them just the impulse which they require to regain the lost tone.

Alteratives.—Arsenic, muriate of ammonia, mercury and iodine have an important role in the therapeutics of uterine fibroids.

Arsenic in the form of the acid or in Fowler's solution given in 1-20 dose of the former and in 5 drop doses of the latter immediately following each meal will often act as a powerful alterative tonic in these cases. While no specific action on the growth of the tumor has been demonstrated, its general effects are frequently so satisfactory in maintaining a general condition of tone that it is strange it has not run the gauntlet of a specific.

Muriate of ammonia, which has none of the tonic properties of arsenic and while inferior in alterative properties, has enjoyed a brief trial as a specific for fibroids. Its principle action, it seems to me, lies in the direction of a hepatic stimulant. By favoring a free portal circulation its action in relieving uterine and pelvic congestion must be obvious. I frequently employ it in 5 to 10 grain doses to be taken in one-half glass of water on rising in the morning. It acts in this way as a very gentle stimulant to the bowels and may be used as a substitute for saline mineral water. As a specific for fibroids, however, one must not place upon it much reliance.

Mercury in the form of blue mass or calomel, is the most valuable alterative, laxative and tonic we have in all pelvic difficulties. Its efficiency and superiority as a laxative lies in the fact that it is our best hepatic stimulant. It unloads the portal circulation, relieves pelvic congestions and favors the rapid removal of waste products from the pelvic organs. It too, possibly from the same reason, increases the patient's desire for food, aids healthy digestion, favors normal assimilation and gives an impetus to the general circulation. My valuable friend and teacher, the late Prof. W. H. Byford, taught me the value of this remedy as a tonic, when properly administered, in gynecologic practice. As a laxative the blue mass should be given in 1 to 2 grain doses every evening for several days, then to be omitted for a like number of days. Following the night dose the next morning should be administered a mild saline laxative, either a seidlitz powder, or from a drachm to two drachms of granulated citrate of magnesia in one-half glass of water. As an alterative tonic it may be given in half the above doses extending over a period of twelve days. Calomel is a convenient form for administering mercury as a tonic and alterative. Triturated with sugar of milk, doses of 1-30 of a grain twice or three times a day may be given for a period of twelve days. An interval of twelve days should then elapse before re-continuing the drug. The bowels should be kept free with saline laxative while the mercurials are in use, and care should be exercised to avoid the unpleasant consequences of administering hydrochloric acid coincident with the drug.

Iodin in the form of tincture applied to the cervix of a fibroid uterus or employed as an application to the mucous membrane has been much employed as a routine treatment for fibroids. As an alterative its effects on a fibroid tumor must be slight, but as a stimulant and antiseptic application to the endometrium of an endometritic uterus it certainly will do good. The injection of iodine into the uterine tumors will scarcely be tolerated as a rational or at least as a desirable treatment at the present day.

Sedatives.—The bromids, the coal tar antipyretics, chloral, cannabis indica, hyoscyamus and opium are sedatives which succeed in relieving the suffering of many fibroid patients and which, when judiciously employed succeed occasionally in tiding them over desperate attacks which would prove fatal without their assistance. In chronic conditions like this one we are considering, no physician should mistake the temporary effects of these sedatives for effects of a curative agent. Symptomatic relief only can we hope from them while we are selecting and marshaling our final conquering remedies.

The bromids are probably as safe and as enduring as any mild sedative, where irritability and general nervousness characterize the patient's suffering instead of actual localized pain. Bromid of potassium, ammonia and sodium mixed in solution given in doses containing 10 grains of each, the doses given at intervals of four to six hours, until nervousness is allayed and sleep obtained, is a favorite method of mine of administering this drug. Frequently the above combination given us a dose at bedtime will accomplish good.

Antifebrin, phenacetin and antipyrin I have found of value in relieving severe menstrual pain accompanying fibroids. By giving them in their appropriate doses at intervals of two to four hours during the pain-

ful period of the menstruation frequently complete relief is obtained.

Chloral is a favorite hospital remedy of mine. I employ it for the uterine pain which accompanies menstruation exclusively—not as a steady remedy. The favorite method of administering it is to instruct the nurse to give 20 to 30 grains in three ounces of water as a small rectal enema not oftener than once in four hours for severe pain or sleeplessness. It does not affect the stomach when given in this manner, and the method of administering the remedy serves to make it unpopular to the patient. In fact, an effort is made to keep the patient in ignorance of the contents of the enema.

Cannabis indica as a remedy for pain in menstrual difficulties is one which I have never learned to appreciate. The remedy is so uncertain and variable in its actions that I usually resort to something upon which I have greater reliance. If a pure article can be obtained a pleasant combination of cannabis indica in extract combined with ergot and valerinate of quinine for the pain of fibroid menorrhagia may be employed with advantage. The extract of cannabis indica in from $\frac{1}{4}$ to $\frac{3}{4}$ of a grain, the ergotin in from $\frac{1}{2}$ to 1 grain, and the valerinate of quinine in 2 grain doses, makes a powerful uterine tonic, the cannabis indica and the valerinate modifying the pain which otherwise would be aggravated by the necessary effects of ergot and quinine.

Hyoscyamus, belladonna and stramonium are valuable sedative remedies to employ as alternatives in the long medical treatment which one is often obliged to conduct before these patients decide to have radical means adopted. While one sedative, hypnotic or anti-irritant remedy after another is being employed these remedies will often give surprising aid as a temporary substitute for remedies which for prudential reasons we feel should be discontinued. The active principle hyoscyamin or atropin may be given in solution in appropriate doses. Or may be given in the small granules which are so accurately compounded by the large manufacturers of pills. I frequently combine these drugs with the valerinate, the two making very effectual sedatives or anti-nervous remedies.

Gelsemium, valerian, and asafetida are very valuable drugs, which can be employed with success in the treatment of fibroids. Extract of gelsemium, combined with valerinate of quinine, zinc and iron, acts as a very reliable aid as a mild anti-neuralgic, while in asafetida we have a remedy which the physician could ill afford to lose. Good full doses of asafetida, 4 to 8 grains, four times a day has carried many a nervous, sleepless, hysterical woman successfully through what otherwise would have been a painful menstrual period.

Opium is a dangerous remedy to employ for the pain of fibroids. The remedy is so prompt and efficient with the majority of patients that it is an easy matter for a dangerous habit to be contracted, inasmuch as the difficulty is a chronic and constantly reverting one. If in desperate cases it is considered wise to employ the drug temporarily, it should be presented by the physician and given, if possible, without the patient becoming aware of the contents of the dose. A condition serious enough, however, to demand the use of opium should also demand some permanent radical means of cure.

Astringents.—Local astringents include such drugs as may be employed with curative benefit by applica-

tion to the mucous membrane of the uterus or by application to the neck of the womb through the vagina. Local astringents may be employed, too, for the temporary effect they may have on the secretions of the uterus or for the direct curative effect they may exert when applied to the mucous membrane of the fibroid womb. When the astringents are applied to modify temporarily the secretions of the uterus, for instance the excessive blood flow, it is best applied on tampons. Alum is cheap and one of the safest and most efficient astringents to use in this way. Wicking, or strips of gauze, or cotton tampons may be prepared and kept for emergencies, by dipping them into a 20 per cent. solution of alum in hot water and then evaporating the water of solution by exposure to the air. This leaves the alum thickly deposited in the interstices of the material. It is only necessary then to apply the tampon directly to the bleeding cavity, allowing the fluids of the cavity to dissolve the alum, or it can be placed in warm water immediately before applying. Excessive bleeding from the uterus which fails to yield to other remedies will seldom fail to be controlled by well placed uterine tampons well saturated with alum. Wicking or strips of gauze without knots is the best material to employ. The patient should be placed in Sims' position, the neck of the uterus grasped with a strong tenaculum, so as to expose the canal, then by means of a bulbous-pointed uterine sound, the material should be systematically packed to the bottom of the uterus. Only where the hemorrhage is alarming is this procedure necessary. In ordinary bleeding a well-placed vaginal tampon alone is necessary. For vaginal tampons, Byford recommends compressed sponges saturated with alum. They are made by taking a fine sponge, large enough to fill the vagina, passing a strong string through the center to aid in its removal, and then after dipping it in the solution of alum, well winding it with twine from one end to the other, compressing it into as small a space as possible. The twine should so compress the sponge as to make it assume an elongated form. It should then be laid aside and permitted to dry. Several of these should be kept on hand by the patient, she having been previously instructed how to employ them. After compression and drying it will be of small size, and such shape that it can be easily introduced into the vagina, while the moisture of the parts will soon cause it to expand into an efficient tampon.

Astringents when applied to the mucous membrane of the uterus, are applied ordinarily for the curative effect they may exert on the inflamed endometrium. For this purpose the tincture of the chlorid of iron is a popular astringent. I have employed with benefit a 10 per cent. solution of chlorid of zinc in glycerin and water. Varying strength solutions of nitrate of silver have been employed. This is objectionable, however, because of the indelible stain produced by it. There is such a large variety of well-known astringents which may be employed for this purpose that it seems like needless waste of time to enumerate them.

The application to the mucous membrane should be made, after the cervix has been exposed, by means of a flexible applicator wrapped with cotton. The canal should first be wiped free as possible of all secretion by means of the applicator and cotton and when that is accomplished the mucous membrane should be thoroughly painted with the astringent by passing the applicator, well wound with absorbent

cotton, and saturated with the drug, to the bottom of the uterus.

General Astringents.—Of the astringents which reach the uterus and modify uterine hemorrhage when given internally I know of none which compares with *hydrastis canadensis*. It contracts the blood vessels and modifies the hemorrhage. It is so efficient that one is led to believe that it has a direct contractile effect upon the muscular walls of the uterus and tumor. While it acts as an astringent with special predilection for the uterus it also is efficient as a bitter tonic. The fluid extract may be given in doses of a third to one-half a drachm three or four times a day. I frequently combine the solid extract with ergot in grain doses of each in form of capsules, one three or four times a day. This drug actually seems to possess a curative effect not only in diminishing the amount of the blood discharge but also in decreasing the size of the tumor. When employed to modify hemorrhage it should be given in good maximum doses of one-half to three-fourths drachm of the fluid extract three or four times a day during menstruation. If it is to be employed as a direct curative agent it can be more conveniently and elegantly administered in capsule form as already indicated either alone or combined with other uterine tonics.

Tincture of *cannabis indica* in from four to ten drop doses given during the approach and continuance of menstruation not only modifies irritation but also acts as an astringent and hemastatic.

Special uterine tonics.—Ergot has occupied such a conspicuous and important role in the treatment of fibroids of the uterus that I deem it advisable to devote a special article to its consideration.

The foregoing article can be briefly summarized as follows:

1. The medical therapeutics of fibroids of the uterus are divided into general tonics, alteratives, sedatives, astringents and special uterine tonics.

2. General tonics: Judicious and systematic feeding; bitter tonics including quassia, calumba, nuxvomica and cinchona; iron; prepared foods of all kinds. Nerve tonics: The hypophosphites; strichnia and manganese. Bowel tonics: Aloin and cascara sagrada. General stimulants: Hot salt baths; sea salt baths, warm or cool; massage. Local tonics: Hot vaginal douches. Climate: Change of residence, travel and ocean voyage.

3. Alteratives: Arsenic; muriate of ammonia; mercury; iodine.

4. Sedatives: The bromids; the coal tar antipyretics; chloral; asafetida; valerian; gelsemium; hyoscyamus; opium.

5. Astringents: Local, alum; chlorid of zinc; preparation of iron. General astringents: Hydrastis; *cannabis indica*.

6. Special uterine tonic: Ergot.

Treatment of Syphilis.—The Société de Dermatologie has been considering the question of mercurial injections in syphilis, devoting two meetings to it. The conclusions seem to be that its use should not be limited to severe cases, but that it is beneficial in all, and the best means of administering mercury, on account of its reliability, rapidity, and the intensity of its action. Le Pileur has treated 600 cases with injections of gray oil, which he especially recommends. Hallopeau and others prefer to this injections of calomel.—*Progrès Médical*, February 8.

THE PROPER INDICATIONS FOR REPAIR OF PATHOLOGIC LACERATIONS OF THE CERVIX UTERI, AND THE PROPER OPERATIONS TO MEET THEM.

Read at the meeting of the Mississippi Valley Medical Association, at Detroit, Sept. 5, 1895.

BY ALBERT GOLDSPOHN, B.S., M.D.

PROFESSOR OF GYNECOLOGY, CHICAGO POST-GRADUATE MEDICAL SCHOOL; ATTENDING GYNECOLOGIC SURGEON AT THE GERMAN, THE POST-GRADUATE AND THE DEACONESS HOSPITALS OF CHICAGO.

The recognition of a distinct pathologic bearing of many parturient lacerations of the cervix uteri, and the devising of one of the operative procedures for repairing the injury, by Dr. T. A. Emmet, is probably one of the foremost improvements in minor gynecology in the last twenty-five years. And although the Emmet operation is essentially incompetent to meet all the indications in all properly selected and prepared operative cases of this nature; still its name might be fairer had its importance not been overestimated in the beginning; had it not in a large proportion of instances been ignorantly or carelessly pressed into service, where or when no operation whatever on the portio vaginalis was indicated; or if it had always been properly executed. But the Emmet operation is not the only one that has suffered such abuse. Most other procedures upon the cervix or its canal can make equal claims for redress and limitation to proper indications.

In this connection it is pertinent to note that to one who comes frequently in contact with general practitioners as in consultations or in post-graduate classes in gynecology, it becomes very evident that their views of pathology in the female pelvis are based altogether too much upon things they find in the gynecologic vestibule—the vagina—as seen through the speculum or felt with a finger or two, with one hand only. While these intelligent gentlemen, successful general practitioners, ambitious to be up with the times, are well aware of the fact that the most important portion of the generative organs is located higher up, they seem possessed of the idea that whatever exists up there, aside from marked tumefactions and displacements, must have had its origin below somewhere in the vaginal portion of the uterus or its canal; that something must first be repaired or straightened out there before any disorders above can get better; that when the former has been done, the latter will follow of their own accord “in time” and with “proper care;” that repairing the sheepfold at the place where the wolf entered will make good all the ravages that he committed within, is the delusion to which they are still led on by the original positive statements of the promoters of trachelorrhaphy in their text-books, who said that subinvolution, metritis, retroversion of uterus and tender ovaries would practically be done away with by removal of the “cicatricial plug” and overcoming the ectropion. Gynecologists generally know now from experience usually well paid for, that this is not so. They know that organic disorders of pelvic organs located above the vagino-abdominal diaphragm that have arisen as ulterior effects of cervix laceration, become separate entities and require treatment suited to themselves nearly the same as if no lacerated cervix figured in the case; and they know, moreover, that when such a policy of treatment is carried out the patient very frequently recovers enduring health with-

out any cervix operation. While such knowledge is in possession of able specialists who are familiar with the opinions and experiences of most of the world's authorities and greater operators, it has not penetrated through the general rank and file of honorable and efficient general practitioners, who naturally have not the time to thresh the great international stack of medical journals, society reports, etc., but are limited to the opinions of a few authorities briefly expressed in the text-books. The text-books are the principal guide to general practitioners in matters apart from general medicine, and oftentimes in the whole domain of medicine and surgery. I am constrained to attribute much of the defects and inconsistencies in gynecology as it is practiced by general practitioners and some self-styled specialists to the text-books; and chiefly to those of our own glorious country.

Thus while Emmet in the 3d edition (last) of his “Principles and Practice of Gynecology,” admits that he would not do trachelorrhaphy in a number of conditions where he had previously operated, he inconsistently retains a most unfortunate and unguarded statement from the previous editions. He opens the chapter on this subject by saying: “The importance of this injury can not be exaggerated;” (!) since at least one-half of all the ailments among those who have borne “children are to be attributed to laceration of the cervix.”

To say that one-half of all the gynecologic ailments, even of parous women are due to this cause, would be an exaggerated statement which the experience of the last twenty-five years has abundantly disproven. And to say that half of all the ailments—general, medical and surgical included—are due to this is so much greater an error. For the feminine body, minus its generative organs, does have ailments also, quite as well as that of the male minus its sexual organs. And if we, for the sake of generosity in argument will assume that half of all the ailments of parous women come from their reproductive organs, and the other half from all the rest of their bodies combined; then the logical conclusion would be that laceration of the cervix uteri causes all the gynecologic ailments in parous women, if Dr. Emmet's dictum were correct.

Thus, we have a praiseworthy subject crippled at its introduction by an unfortunate exaggeration of its importance by its own author; and is it surprising then if thousands of practitioners and scores of improvised specialists, who justly bow to the fruitful views, valuable suggestions in treatment and authority of Dr. T. A. Emmet on nearly every other gynecologic subject, have looked to the cervix uteri and no further, for the source of nearly all gynecologic disorders, and have operated for imaginary sources of irritation more frequently than for real ones? They can not all know that six years later (1890) in an excellent paper at Toronto, Canada¹, he trimmed the indications for his operation down to “relief of certain reflex symptoms accompanied by more or less impaired nutrition, and to guard against the occurrence or epithelioma,” after ample previous treatment; and that, to escape the need of trachelorrhaphy, he advised a potent course of treatment of the parts during the puerperal state consisting of hot water vaginal douches, weak sublimate intra-uterine irrigations, Churchill's tincture to the cervix and vaginal vault, three to four weeks recumbency, ending in efficient tamponade of vagina when

¹ Canadian Practitioner, vol. xv., p. 313.

indurations above or descent of the uterus exist.

And while the other more recent text-books have taken a fairly reasonable view of trachelorrhaphy, they state merely the "Emmet pathology and treatment of this subject" and fail,—

1. To proclaim and to reiterate, with emphasis, the important principle or rule of action, that a complete diagnosis of the woman and of her pelvis must be made before any operation whatever on the gynecologic uterus is permissible; that by skillful and well disciplined bimanual palpation, almost wholly, in anesthesia when required, the position, mobility, size, shape, consistence and tenderness of the entire uterus, the location, mobility, size and tenderness at least of usually both ovaries, and any material departure from health in the tubes, ligaments and pelvic peritonium must first be secured before the question of indication for cervix operation of any kind can be decided.

2. The text-books fail to impress upon their readers as irrevocable common law, that aside from some reflex neuroses, all organic pathologic conditions above the vagina that follow by infection and otherwise, in the retinue of cervix laceration, become separate objects for treatment, independent of the cervix, and should receive such treatment previous to the repair on the cervix, or in the same narcosis with that operation.

The substance of such rules and principles prefaced to each of the principle minor operations in the text-books, would soon eliminate the frequent instances where pathologic conditions of a minor grade, receive an impetus in the wrong direction which lands them where major operations only can avail; when a correct understanding of the whole case and supporting of nature's processes would have secured more nearly a normal woman by minor means.

As to the Emmet operation, time forbids that I should quote the numerous derogatory statements in the literature by thorough gynecologists as to its poor, bad and positively harmful results. Such are known to all men in extensive general and special practice. And, alas! among the laity they have too often been stumbling blocks that have induced women who needed other very important operations, to while away their day of grace.

There are many who eulogize trachelorrhaphy. But their number is constantly decreasing and they are usually young aspirants who, with broader knowledge and more experience, will become more reserved in their statements. The critics of this operation usually ascribe its negative results to its being done defectively or out of place. But I hope to show by touching upon the several views of the pathology, and a brief review of the morbid processes in childbirth that the operation is itself unable to cover the whole ground.

A view that is entertained by many, chiefly Europeans, and expressed by Wm. R. Pryor,² is, no doubt, correct in many cases; viz., the cervix that tears is usually one that was hypertrophied or hardened previous to pregnancy; that it was then in a state of fibrosis or connective tissue hyperplasia, viz., a diseased cervix, and therefore tore; that the erosion is caused by the outflow of purulent discharge from the associated endometritis, so that if any operation at all is indicated it is curettement and amputation of the cervix; that sewing such lips together is worse than nothing.

2. The view of Schroeder is, no doubt, also often nearest the truth: that lacerations of the cervix being so frequent that they may almost be looked upon as physiologic, in themselves tend to heal spontaneously unless something gets into them and prevents coaptation of the torn surfaces. And this obstacle is presented by the previously diseased catarrhal mucous membrane lining the canal. And as the canal is flat and has acute angles laterally it prevents the healing of those tears mostly that occur on the sides. And therefore extirpation of this diseased lining of the canal with its degenerated mucous glands is indicated, with reunion of the severed lips when necessary.

3. The view of Emmet assumes the deeper muscular and fibrous tissues of torn cervixes to have been healthy previous to pregnancy and labor, and regards the laceration as the original evil, causing disease of columnar mucous membrane by its exposure. He assumes that involution in the cervix is arrested, because its lymph and vascular channels are laterally obstructed by cicatricial formations in the angles of the tears. This does not seem rational when, as he assumes, these channels are in action in the interior—the greater portion of the cervical lips.

When lacerations occur in cervixes whose mucous lining and other tissues were perfectly healthy before pregnancy, the Emmet order of events is correct. But while each of these three views presents a part of the whole truth, we need to ascribe more importance to the element of infection, inflammatory action and its residua.

According to the investigations of Doederlein,³ Burguburu,⁴ Williams⁵ and Burkhardt,⁶ the vagina of every pregnant woman contains saprophytic germs and in nearly half of all cases, pathogenic germs are present in it. In recumbency the vagina of the puerperal female is almost never empty but is simply overflowing most of the time. This basin presents admirable conditions for bacterial culture and the fluid contained in it is never strictly aseptic, although it contains pathogenic germs in only about 40 per cent. and the dangerous streptococci in 4 per cent. of cases unmodified by douches, examinations, etc. It will arouse a variable degree of inflammation in the lacerated cervix that is either immersed or periodically dipped in this fluid, even when it can or does not induce puerperal fever. Such inflammation will not be limited superficially to the torn surfaces but it will engage the columnar mucous membrane and muscular and connective tissue substance of the bodies of the severed lips.

Involution is arrested by the inflammation which converts it from the state of subinvolution into that of fibrosis or connective tissue hyperplasia. Thus, if the cervix was not hard and diseased previous to pregnancy, it becomes so now. The hard tissue encountered by the needle in the Emmet operation is formed. It is studded with diseased submucous glands and is more of an irritating focus than are the much smaller cicatricial plugs removed by the Emmet procedure. And the enlarged Nabothian follicles that are distributed beneath the mucous membrane deeply in the diseased bodies of the cervical lips must be regarded, not merely as hypertrophied glands, but as a graver feature tending toward malignancy, in view of facts learned by extended histologic

⁶ Archiv f. Gynecologie, Bd. 45, Hft. 1.

studies of the earliest malignant infiltrations here. Therefore, extirpation of all tissues containing such cystic follicles is needed, and not merely puncturing them and then hiding them, as is done in the Emmet régime.

Now in order to do away with the customary guess-work with which physicians have usually plied the question, whether a given case required operation or not; and on the principle that the laceration itself, *per se*, is innocent, that its evil results alone are pathologic and may need removal in cases where they have supervened.—I analyze these results under the following four points, which must be objectively demonstrated by touch, and can be guessed at only by sight. They are:

1. *Cervical Diastasis at the Vaginal Attachment*, produced only by very deep lacerations that extend above the vaginal insertion. Then traction of the anterior and posterior vaginal walls may draw the torn flaps of the cervix apart and will usually tilt the fundus backward. All tears that do not extend beyond the portio vaginalis uteri, and whose torn surfaces are covered by normal vaginal mucous membrane and that are bounded by normal elastic and flexible cervical tissues throughout the entire cervix, are not pathologic, no matter what be their depth.

2. *The Cicatricial Plug or Wedge* at the bottom or angle of each tear.

3. *The Columnar Mucous Membrane* lining the outer portion of the cervical canal and covering the inner side and tips of the everted cervical lips, which is diseased by hypertrophy and adenoid degeneration, and is commonly called "an erosion."

4. *The Indurated Body of each Lip*, meaning the entire stratum of hardened cervical tissues in each lip, which underlies the membrane last mentioned, and embraces most of the Nabothian follicles.

Two or more of these four features must be present in any given case before we can say that the cervix may possibly be a source of irritation, or is pathologic. But to say that it is such, that it is what makes the woman sick, is another question altogether; and before we can answer it we must make a general diagnosis of the entire woman and a detailed one of her pelvis, not merely of the vaginal vestibule. We need to be aware of every anatomic and functional derangement that may be present in any of the other principal organs or systems of the body, before we can possibly judge fairly how much of the patient's sickness is due to these, and how much to her pelvic conditions. And then, coming to the pelvis, we must not let our eyes and a speculum deceive us and be overawed by cosmetic infringements in the vagina. But when the intestines have been properly emptied of feces and gas and the bladder is empty, we must by simple digital palpation, and by vagino-abdominal (bimanual) or by recto-vagino-abdominal (trimanual) palpation search for the four pathologic features about the torn cervix; determine the position, mobility, size, shape, consistence and tenderness of the entire uterus; ascertain the location, mobility, size, tenderness and contour (as to cystic follicles) of usually both ovaries; and find out any material departure from health in the tubes, ligaments and pelvic peritoneum. Nor dare we overlook anything about the rectum, perineum or bladder. Not until we have thus surveyed the entire pelvis and have carefully weighed the pathologic bearing of every abnormal feature in it, can we possibly judge as to the harmfulness or inno-

cence of lesions about the cervix, be they ever so marked.

Distinct extra-uterine swellings, aside from mere thickenings and retraction of ligaments, when they continue longer than six or eight weeks after a labor, miscarriage, or other occasion for inflection, are not cellulitis, as expressed by Emmet, but disease of appendages, and adjoining peritoneum, or the results of such disease; or they are neoplasms; and they will contra-indicate all cervix repair as long as they give pain locally, or are markedly tender on pressure, or are aggravated by the passage of a galvanic current of moderate amperage through them; unless in the judgment of a competent gynecologist they are amenable to minor means, and it is thought that their chances would be improved by eliminating a suspicious endometritis by a thorough curettement, packing, etc. Then the cervix operation may be done also incidently.

When, as is so frequently the case, a lacerated cervix is accompanied by a retroversion or flexion of the uterus, and is adherent or not normally movable, especially when one or both ovaries are also descended, operating on the cervix is contra-indicated until all adhesions and other hindrances to normal anteversion have been overcome by the usual means, supplemented by skillful pelvic massage. If this proves to be unavailing in competent hands, then curettement and intra-abdominal work will be needed, not to remove anything unless it is hopelessly diseased, but to liberate the organs and to secure them in their proper positions; and not merely a little whittling enterprise on the cervix: that would but aggravate the principal disorders. But in 95 per cent. of all such cases pelvic massage will achieve this liberation of the organs and will restore them to their proper realms, with nothing but their own weight to hinder them from remaining there.

When this preliminary victory has been gained, and not until then, the following series of operations is in order, which I do usually in one narcosis:

1. Curettement and packing, to take care of the co-existing endometritis and to make a surgically clean field.

2. Operation for lacerated cervix.

3. To hold the uterus in anterversion, shortening of the round ligaments is most serviceable and satisfactory in the great majority of well prepared cases. But ventro-fixation will have to be chosen for some, and vagino-fixation for others.

4. Posterior kolporrhaphy and perineorrhaphy are often required to meet all indications.

Endometritis is the regular accompaniment of all pathologic lacerations of the cervix; and any secondary operation for cervix repair, without a preceding careful, and intelligent curettement or without a narcosis, is botchwork.

PROPHYLACTIC TREATMENT.

Large tears that occur in hospitals and elsewhere, when a competent nurse and appointments for aseptic detail are at hand, should be sewed up primarily within a few hours after labor; as has been done and advised by Pallen, A. P. Dudley,⁷ Garrigues,⁸ C. Kollock,⁹ C. C. Barrows,¹⁰ H. T. Byford,¹¹ and many others. But whether they be sewed up or not, sur-

¹¹ H. T. Byford, Tr. Ill. State Med. Society, 1894, p. 495.

gical cleanliness of the parts should be maintained by suitable douches. The evil results of a tear are alone pathologic; and these may be largely prevented by eliminating the element of infection and inflammation, by interfering with the developments of both pathogenic and saprophytic or fermentation germs. This declaration is testified to by: 1. Dr. T. A. Emmet, who says that in cases where the stitches are taken out on account of infection a few days after trachelorrhaphy has been done, and the cervix is not re-united, but the freshened surfaces are allowed to glaze over with a vaginal mucous membrane under efficient hot water douches and other guards against infection, the benefit to the patient's health is about the same as if it had all primarily united.

2. This declaration is testified to by the fact, which can frequently be observed, that lacerations in the cervix that have been protected from constant or frequent contact with fermenting or positively septic lochia by antiseptic, or aseptic vaginal, or vaginal and intra-uterine douches, skillfully administered, will afterward be found healed over with shining vaginal mucous membrane and not associated with the pathologic features which I have detailed. Therefore the vagina should be redeemed from being an undisturbed culture bed for germs.

CHOICE OF OPERATION.

In the rare instances where only gaping of the cervix at or above the vaginal attachment exists, or the cicatricial plug alone, or both of these together, *i. e.*, Nos. 1 and 2 of my pathologic features, with no diseased columnar mucous membrane and no indurations or cystic follicles in the body of the lips, the Emmet operation will fill the indications. This will be more likely in cases of early trachelorrhaphy, as it is named by J. J. Mulheron,¹² who advised sewing up tears in childbed about two weeks after labor.

But in some of these early cases even, and in nearly all cases that really need operation later on, the principal indication for removal is presented by points 3 and 4 of my description; viz., the diseased columnar mucous membrane covering the longer median portion of each lip, and the entire mass of indurated cervical tissues composing the body of each lip and containing most of the dangerous submucous cystic follicles.

These principal sources of irritation and of malignant developments the Emmet operation can not cope with, without doing more harm than good by impairing uterine drainage. In at least four-fifths of all secondary cases the entire indications are best fulfilled by a suitable adaptation of the operation devised by the lamented Schroeder of Berlin, for excision of catarrhal mucous membrane from the cervical canal. It was published by him in this country in 1882. It is as follows:

1. Exsection of the cicatricial wedge at the bottom of each tear by two suitable incisions which meet near the internal os, forming acute angle with each other. When there is only a unilateral tear and diseased cervical tissue and membrane are to be removed, then one simple temporary incision of equal depth is made in the cervix at a point opposite the tear. By holding the two cervical flaps thus made apart by bullet forceps, the entire cervical canal becomes accessible.

2. A cross-cut is then made on one lip extending in length to about one-eighth or one-fourth of an inch

from the lateral boundaries of the cervix, and of sufficient depth to pass through the mucous membrane and all indurated cervical tissue beneath it. This cut is made as high up in the cervical canal as is needed to remove all diseased parts and still admit of the subsequent suturing. From this incision downward to the end of the lip, the entire mucous membrane and with it all the adjacent hard cervical tissue, with all the diseased follicles in it, is removed in one piece, so that a hollowed-out flap of the soft and flexible outer vaginal portion of the portio vaginalis is left. This is then flexed inward upon itself, and its end sutured by four to six catgut sutures to the projecting shoulder above (and created by) the transverse incision.

3. The other lip is next treated in the same manner.

4. Finally, three or four silkworm-gut sutures are introduced on each side similarly to the Emmet sutures.

Thus a short and broad cervix or portio vaginalis is made, whose external portion is lined by squamous epithelium that will never degenerate as the less resistant columnar mucous membrane does, from numerous local causes, and stenosis of the cervical canal is never invited, as it often is by the Emmet operation.

A CONSIDERATION OF THE VALUE OF THE ALEXANDER OPERATION COMPARED WITH THAT BY ANTERIOR FIXATION OF THE UTERUS.

Read before the Gynecological Society of Boston, Feb. 13, 1896.

BY AUGUSTUS P. CLARKE, A.M., M.D.

CAMBRIDGE, MASS.

Alexander's operation seems from the most recent experiences to be indicated only in those cases of backward displacement that are not complicated with adhesions and pelvic contraction. When the displacement is due to morbid processes connected with the Fallopian tubes and ovaries the Alexander operation would be for the most part contraindicated. The operation can only be resorted to with advantage in cases of mere relaxation of tissue. In cases of adhesions it is plain that the contracted parts would draw upon the bladder. In uncomplicated cases the operation would insure the uterine fundus, being held over the bladder more in accordance with its normal relation than can be secured by a resort to the other surgical procedures. Speaking from my own experiences and observations I should say that the indications for Alexander's operation are extremely limited. The operation, though a delicate one, is often quite formidable and, unless its application is narrowed down to the cases in which it must be employed, the measure for relief will prove a failure. Most of the apparent cures following the Alexander operation result not so much from its adoption as from the measures employed to relieve many concomitant lesions. Metritis, endometritis, salpingitis and ovaritis are conditions that often accompany retro-position. Curettage and other surgical expedients employed for the relief of these affections are often most helpful in overcoming displacement. Some operators employ for some weeks after the operation as a precautionary treatment different forms of pessaries. Careful and judicious application of iodoform gauze tampons is sometimes preferable to the use of the regular pessaries. The employment of such means and the keeping of the patient in bed or at rest contribute no doubt to the relief experienced. The special features of treatment such as rest and the

¹² Canadian Practitioner, vol. xv, p. 346.

securing of greater nutrition may often assist materially in lessening the retro-position. Some have reported cases in which the Alexander operation has been employed for overcoming prolapse. The results of such cases must be regarded as negative, for the reason that the proper function of the round ligaments is rather to prevent a backward than a downward displacement.

Mr. Bland Sutton tells us that except in the human female the round ligaments are found only in the chimpanzee and the higher apes. The function of these ligaments in those animals is also to prevent retro-displacement. In downward displacement or prolapse other surgical procedures, such as anterior colporrhaphy, and, in intractable cases, vaginal hysterectomy are the means resorted to for a cure. In cases when inflammation and laceration are the causes, curettage of the uterine cavity, trachelorrhaphy and perineorrhaphy may have to be employed. In cases of backward displacement in which there are adhesions abdominal section or celiotomy (hysterorrhaphy) may advantageously be employed. This is especially indicated when the retro-position continues after other lesions have been attended to. Certainly hysterorrhaphy is more dangerous than the Alexander operation. In hysterorrhaphy or anterior fixation it is surprising to observe what a small band of union will keep the uterus properly anteposed after it has been restored. It is the intra-abdominal pressure that is exerted from behind as well as from before or from above that sustains the uterus in its normal position over the bladder. When, however, the uterus has undergone a backward displacement the intra-abdominal pressure is merely downward upon the organ. Pressure high up, or drawing from below tends to overcome the supports rendered by the round as well as by the utero-sacral ligaments, and so gives rise to the retro-position. The shrinking or the contraction that generally takes place in the round ligaments may serve to restore the displaced uterus. In some cases the round ligaments are very frail and may be found to have undergone fatty degeneration and atrophy. Anterior fixation through an abdominal section may, after the appendages have been removed, be effected by suturing the pedicles to the peritoneum and sub-peritoneal fascia on each side of the incision; in such cases a single suture passed through the uterine wall may suffice. There will, therefore, be less traction or sense of discomfort complained of by the patient before she has become accustomed to the presence of the uterus in its restored position. The fixation in this manner for the most part in any case gives rise to unnatural sensations. The Alexander operation, when successfully performed, is a more scientific procedure, though there is danger of establishing a too firm fixation in this direction. Ventro-fixation may interfere very seriously with the progress of pregnancy, and should rarely be resorted to in virgins or in women who have not reached the menopause, unless the adnexa have been removed by reason of disease or morbid changes. Vaginal fixation is sometimes employed as a means of relief for retro-position. The extended incision rendered necessary to effect a separation of the bladder from the vagina may lead to troublesome vesical symptoms. Some operators advise that the inner surface of the ligaments on either side be scraped and their raw surfaces be folded together and sutured. The sacro-uterine ligaments may be folded through an abdominal or a vaginal

incision. The history of the results of such surgical expedients has not been as satisfactory as that of the relief obtained from the Alexander operation and hysterorrhaphy. It should be again observed that the Alexander operation as well as hysterorrhaphy when resorted to in women who have not reached the menopause may so firmly fix the uterus as to interfere seriously with the development of a normal pregnancy.

The patient should be made aware of the full consequences of either operation and be made to recognize the possibility of not being able afterward to carry a child to the completion of pregnancy. In certain cases of retro-position when the patient is to remain unmarried, or has passed the menopause, these measures of relief may be excellent expedients.

LOCOMOTOR ATAXY ASSOCIATED WITH SYPHILITIC CEREBRO-SPINAL MENINGITIS.

Read at the meeting of the Chicago Academy of Medicine, held
February 14, 1896.

BY SYDNEY KUH, M.D.

CHICAGO.

Late Assistant to Professor Erb, of Heidelberg; Professor of Nervous Diseases, Post-Graduate Medical School; Attending Neurologist, St. Elizabeth and Michael Reese Hospitals, Michael Reese Hospital Dispensary and U. H. C. West Side Dispensary; Consulting Neurologist, Home for Aged Jews and Home for Jewish Orphans.

For some years we have known that syphilitic disease of the spinal cord may simulate the symptoms of locomotor ataxy. More recently we have learned that tabes dorsalis may occur simultaneously with true syphilitic lesions of the spinal cord or its membranes. In 1890 when examining the central nervous system of a patient who died while suffering from locomotor ataxy for changes in the cortex of the brain, such as had been described by Jédrassik but a short time previously, I was surprised to find changes in the membranes of the brain and spinal cord, such as had not before been seen. The history of that remarkable case and the result of the microscopic examination were as follows:

The patient, a well-known actor, 36 years of age, had had an ulcer glandis penis when 20 years of age. He had a course of inunctions and never suffered from secondary symptoms. His occupation exposed him to frequent sudden changes in temperature and necessitated a good deal of intense mental exertion. There was no neuropathic disposition in his family; he had never used tobacco or alcohol to excess, and had never suffered any trauma. In 1887 he had a sudden attack of vertigo. Very shortly afterward he was examined by Professor Erb, of Heidelberg, who found the following symptoms: Impotence, wide and unequal pupils which did not react to light, slight swaying when eyes were closed, absence of knee jerk, slight diminution of sensibility, particularly to pain in the toes of both feet. After forty inunctions and continued electric treatment there was some improvement. During the following year the patient suddenly became worse. There was ataxy, more marked swaying oculis clausis, greater impairment of sensibility and paresthesia in lower extremities and in the ulnar nerve, lancinating pains. In September of that year Charcot's joint developed in the right knee and the beginning of a similar condition in the left knee became noticeable. In March of the following year he died quite suddenly. Up to the last day his mind had remained perfectly intact.

At the post-mortem examination the bones of the skull were found to be very much thickened. The heart was enlarged. There was degeneration in the posterior columns of the spinal cord, but the record contains nothing about changes in the membranes. The spinal cord and brain, the pneumogastric nerve, cerebral and spinal arteries and part of the cauda equina were hardened in Mueller's fluid and stained with Weigert's hematoxylin, borax carmin, alum carmin and Delafield's hematoxylin. In order to render the results as reliable as possible normal material was hardened and stained by exactly the same methods.

The changes found were briefly as follows: Typical tabetic changes in the spinal cord, most pronounced in the lumbar region. On a level with the upper portion of the decussation of the pyramids some of the axis cylinders in the columns of Goll and Burdach were swollen, others atrophied; the medullary sheaths were broken up into globular fragments, while the neuroglia was totally unaltered, or in other words, purely parenchymatous degeneration had taken place. Besides this we found peri-, end-, and mes-arteritis in the vessels of the membranes of both the spinal cord and the brain, and a leptomeningitis which extended from the cauda equina to the cerebrum, involving the convexity of the brain to a greater extent than its base. The cause of the sudden death was probably a series of minute fresh hemorrhages in the immediate neighborhood of the nucleus of the pneumogastric nerve. In the dentate nucleus of the cerebellum the nerve cells were undergoing a process of degeneration, a condition which according to recent investigations by Jellinek (Ueber d. Verhalten d. Kleinhirns bei Tabes dorsalis. *Deutsche Zeitschrift f. Nervenheilkunde*, 1895, VI, Bd. 3 and 4, p. 231) appears to be a common occurrence in tabes. That the meningitis was of a syphilitic nature was proven by the existence of a typical gumma in the pia mater of the anterior portion of the cervical region. In the pneumogastric nerves the blood vessels were increased in number, their walls contained an abnormal number of nuclei, were thickened, infiltrated with round cells here and there. Similar accumulations were seen between the nerve fibers and some of the latter were distinctly diseased, the changes being similar to those described in the region of the decussation of the pyramids.

Since the publication of this case a number of similar observations have been placed on record by others.

Thus Dr. Jegorow,¹ at a meeting of the Society of Neuropathologists and Alienists of Moskau held on Jan. 18, 1891, reported a case in which the symptoms of tabes (absence of deep reflexes, Argyll-Robertson pupils, sensory disturbances) were associated with inferior paraplegia and atrophies and the post-mortem revealed the changes characteristic of locomotor ataxy, meningitis in sacral region, syphilitic disease of the blood vessels and a number of fissures in the spinal cord. In the same year Dr. G. Marinesco² reports four cases of locomotor ataxy in at least two of which tabes was combined with tertiary syphilitic lesions in the central nervous system.

In 1892 Dr. M. Dinkler,³ of Heidelberg, read a paper entitled: "A Case of Syphilitic Tabes," in which he gives the history of a patient, 42 years of age, in whom the first symptoms of tabes developed nine years after the primary lesion. Clinically the case was typical: Impotence, lancinating pains, girdle sensation, Argyll-Robertson pupils, miosis, analgesia, right knee-jerk less marked than the left. The patient succumbed to a cerebral hemorrhage. Besides the tabetic degeneration there were found milary aneurysm of the cerebral arteries, syphilitic leptomeningitis with small gummata and multiple hemorrhages.

In Minor's⁴ case a woman, 26 years of age, developed the symptoms of a myelo-meningitis of the dorsal region five years after the probable infection. To these symptoms were added those of locomotor ataxy, such as absence of deep reflexes, Argyll-Robertson pupils, myosis, lancinating pains. After treatment with mercury the paraplegia disappeared, while the symptoms of tabes remained unchanged. Here, too, cerebral lesions were the cause of death, and the post-mortem showed not only that the diagnosis of locomotor ataxy had been correct but that in addition to this a diffuse syphilitic leptomeningitis with gummatus periarteritis in the spinal cord had existed.

⁴ Heml- und Paraplegie bei Tabes. Zeitschrift f. klin. Medicin, xix, 5 and 6.

A seventh case, that published by Dr. M. Nonne,⁵ was somewhat more complicated. His patient, a man 44 years old, had a chance in 1870. Seventeen years later ataxy, Romberg's symptom, myosis, Argyll-Robertson pupil, absence of deep reflexes and atrophy of optic nerves were found. In 1890 subacute paraplegia developed in the upper extremities. Death one month later from apoplexy. Again the changes characteristic of tabes were found in the spinal cord and added to these gliomatosis beginning in the upper cervical region and extending down to the level of the tenth dorsal nerve, a fresh focus of necrotic softening in the cervical region, chronic cerebral leptomeningitis, end- and mes-arteritis of the basilar artery.

Finally, an additional observation of this kind has been published by Dr. B. Sachs⁶ about two years ago. Here we again find the symptoms so often enumerated: Ataxy, lancinating pains, absence of deep reflexes, Argyll-Robertson pupils, miosis, Romberg's symptom, and in addition to these gastric crises and slowness of sensory conduction. Anatomically the typical sclerosis of the posterior columns, syphilitic leptomeningitis and typical specific arteritis existed.

A ninth case published by Dr. C. A. Ewald⁷ is mentioned in some of the papers on this subject, but the microscopic examination showed that it was a pseudo-tabes syphilitica and not a true case of locomotor ataxy. These lesions are very probably not at all uncommon in cases of locomotor ataxy and have presumably not been described more frequently on account of the technical difficulties associated with making satisfactory microscopic sections of the central nervous system when the membranes have not been previously removed. The discovery of true syphilitic changes in the central nervous system proper or its membranes may well be mentioned as an additional factor in the support of Fournier's theory, that locomotor ataxy is very often, if not always, the consequence of a specific infection.

Since this paper was written I have looked over some older specimens prepared in the laboratory of the late Professor Meynert, of Vienna, and have found among them two cases with changes in the spinal membranes identical with those described in this paper, excepting that I could not discover any gumma.

DISCUSSION.

DR. HUGH T. PATRICK—The combination of ordinary syphilis of the nervous system with tabes we must consider an established fact, and there is no reason why it should not be so. A large proportion of all cases of tabes undoubtedly occur in syphilitics, and there is nothing to prevent the ordinary syphilitic lesions from being superimposed upon or combined with locomotor ataxia. In direct relation to what Dr. Kuh has said in his most instructive paper, there are two points I would mention briefly, and the first is the relation of suspension to sudden death of the patient. It has been known for a long time that tabetics occasionally die suddenly with symptoms of cerebral apoplexy, yet nothing can be found post-mortem to account for death. I believe I was the first in this city to suspend an ataxic for locomotor ataxia, and this patient died after suspension. He had, as Dr. Kuh's case did, all the symptoms of cerebral apoplexy, coming on about four hours after suspension. Macroscopically nothing was found in the brain or medulla oblongata, but whether there had been a punctate hemorrhage in the pneumogastric nucleus, I will not attempt to say. Nothing was found with the naked eye whatever. Whether suspension had any influence in producing sudden death, I do not know. The same thing has occurred in cases of locomotor ataxia before the days of suspension, and the connection may be considered problematic.

In speaking of the combination of syphilitic meningitis with locomotor ataxia, we should remember the very interesting work of Redlich, who concludes that locomotor ataxia is nearly always, if not always, the result of a chronic lepto-meningitis due to syphilis. Redlich's work is most interesting and careful. He is rather conservative in drawing his conclusions, and states the arguments both for and against his theory. What he finds is briefly this: That in the normal cord the posterior nerve roots are constricted by the pia mater at their entrance into the cord. There is a distinct constriction of the nerve root where it passes through the pia mater normally. At this point the medullary sheath is normal in many fibers, thinned in others, and in some fibers disappears. Furthermore, in the normal subject the small calibred fibers are arranged at this

⁵ Ein Fall typischer Tabes und centraler Gliese bei einem Syphilitischen. Arch. f. Psychiatrie, etc., xxiv, 2, p. 526.

⁶ Syphilis und Tabes dorsalis. New York Med. Journal, January 6, p. 1.

⁷ Ein unter d. klinischen Bilde, d. Tabes verlaufender Fall von syphilit. Rückenmarkser kraenkung. Berlin klin. Wochenschrift 1893, xxx, No. 12, p. 284.

point of passage through the pia mater at the periphery of the trunk of the posterior roots. It is these fine fibers that go to make up the marginal zone of Lissauer, which is ordinarily the first attacked in incipient tabes. Furthermore, he finds that there are two or three regions of the cord where this constriction of the posterior roots occurs in the most marked degree, viz., the cervical enlargement, and the lower dorsal and upper lumbar regions. These are the regions first affected in locomotor ataxia. At the point where the pia mater normally constricts the posterior nerve root there is ordinarily a vessel more or less circulatory embracing to a greater or less degree the nerve root. Now, if there is any chronic change produced by syphilis which is more constant than another it is arteriosclerosis, a thickening of the vessels generally throughout the system, or localized more here or more there. Redlich concludes that at this point of normal constriction a very slight meningitis will induce a very marked change in the nerve root and in the next place, an affection of this vessel at this place will also produce relatively marked changes in the nerve fibers without very extreme changes taking place in the vessel. There is localization which coincides with the ordinary beginning place of the lesions of locomotor ataxia. Again, it has been shown very conclusively that the lesions in the cord in locomotor ataxia are practically and substantially those of ascending degeneration, which may be produced experimentally or by pathologic processes destroying the posterior roots. I would simply state this, that in considering the so-called complication of syphilitic meningitis with locomotor ataxia, we ought to consider at the same time whether the locomotor ataxia is not really the sequence of the syphilitic meningitis instead of the latter being a fortuitous complication of the former. While that is not conclusive, I think it is to be considered, for the peripheral origin of locomotor ataxia has very strong arguments to support it.

Dr. J. G. KIERNAN said there was one phase of the subject which deserved a little more attention than has been paid to it, namely, whether the luetic lesions were not often the result of lues developing secondarily to the tabes rather than a primary condition. Miner, of Moscow, asserted that the cognate disease, parietic dementia, never occurred except in the victim of inherited or acquired syphilis and asked for cases in which syphilis had occurred in parietic dementals after the development of the parietic dementia. Rippler and a number of others had previously cited cases. Dr. Kiernan had seen eleven such cases, in which the parietic dement in consequence of the disease had contracted lues which ran its course *pari passu* with the parietic dementia. What is true of parietic dementia is very apt to be true of the cognate condition, locomotor ataxia. Fournier places these two conditions, parietic dementia and locomotor ataxia, among the parasymphiloses.

With regard to the cases cited, Dr. Kiernan recalled cases of parietic dementia in which there were tabetic symptoms, and in which cerebral gummata were found. There were also luetic changes in the spinal cord as well as meningeal gumma. Probably they were cases in which, if the lues coëxisted with the locomotor ataxia, it produced the ordinary pathologic changes of the latter disease, and later the gummata.

With reference to one of the points raised by Dr. Patrick, Dr. Kiernan remembers making autopsies in cases of ataxic mental trouble which had led to ataxics dying in an insane hospital, in which a complete examination of the spinal cord, meninges and brain was made and the findings were absolutely nil. There was nothing truly pathologic found either microscopically or macroscopically. Colloid spheres had been found and artefact of that character produced by alcohol. But these artefacts excluded, no other lesions were present. The question here certainly could not be raised whether the meningeal condition was not the primary one and the other changes secondary.

Dr. HAROLD N. MOYER. I am impressed with the progress of this discussion, from the fact that my neurologic friends do not understand all there is to be known about the pathologic anatomy of the nervous system. Indeed, I think it is still in a most chaotic state. We have to unlearn the subject almost as rapidly as it is acquired, and we are getting down, as Dr. Kuh has admirably done in his article, to a thorough, careful study of a few cases, though taking in the whole range of the nervous system; in this way we shall have an accumulation of observations which will perhaps place the pathologic anatomy of nervous diseases on a more substantial basis. When one stops to think of the extent and variety of function and the possibility of change in this extended nervous system, it is no wonder that the pathology of other organs of the body should be far better elucidated. I rise to commend Dr. Kuh's paper, not to discuss it or to differ with him. On a former occasion he drew

extended clinical deductions from pathologic observations with which I did not wholly agree, but I concur heartily in what he has said to-night, and I wish simply to commend this masterly observation in neuro-pathologic anatomy.

Dr. KUH (closing the discussion).—The discussion has opened up an immense field, but I shall not detain you by dealing with all of the points which have been touched upon. I wish to reply briefly to one or two questions which have been raised. First, as to the Redlich theory of the constriction of the posterior nerve roots. It is a very seductive theory. There is only one fault to find about it. There are any number of cases of locomotor ataxia on record examined during the first stage of the disease in which there is not the slightest trace of any changes in the meninges, and I can show Dr. Patrick some specimens which will corroborate this statement. This being true, it does away with Redlich's theory entirely. Beside, I need but call Dr. Patrick's attention to the fact that a very large number of cases of locomotor ataxia begin with cerebral symptoms; how they can be due to constriction of the posterior roots in the lumbar region is something I fail to see.

Dr. Kiernan's theory, that the syphilis in my case might possibly be the consequence of tabes, is very improbable. We can all understand how a patient suffering from parietic dementia is liable to expose himself to the danger of contracting syphilis on account of loss of control over himself, his tendency to indulge in excesses, from lack of judgment in selecting proper victims, etc., but the same thing does not hold good in locomotor ataxia. I mentioned in my paper that one of the first symptoms was impotence, which is more frequent than satyriasis. Besides, we know positively that in this case syphilis did exist; that the patient had contracted a chancre when 20 years old. I have not claimed that the meningitis in this case was the cause of the locomotor ataxia; in fact, my impression is that the meningitis was of much more recent date than the changes in the posterior columns, and it was not by any means more marked around the posterior half of the spinal cord than the anterior. The only gumma found was in the anterior portion of the cord.

Another point which may be of interest is this: We know that a number of cases of locomotor ataxia are improved very materially by anti-syphilitic treatment. Dinkler's statistics show that improvement took place in 75 per cent. of his cases. If specific meningitis is as common a complication of locomotor ataxia as I am inclined to believe, then we have in its existence the explanation for the effects of anti-syphilitic treatment. We all agree that neither mercury nor iodid of potassium can restore the destroyed fibers in the posterior part of the spinal cord; but we can understand how other symptoms might be added and existing symptoms aggravated by meningitis, and that when the latter is improved there results an improvement in the condition of the patient.

SPECIFIC TREATMENT OF NECROSIS OF THE ALVEOLI AND MAXILLÆ WITH AROMATIC SULPHURIC ACID.

Read in the Section on Dental and Oral Surgery, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY W. A. MILLS, D.D.S.

BALTIMORE, MD.

I desire to bring before your attention the non-operative treatment of necrosis of the alveoli and maxillæ with aromatic sulphuric acid. I shall cite only two cases in office practice, entering as little as possible into any minute detail of their history or etiology.

Case 1.—A lady of nervo-bilious temperament, aged 30, called to consult me about a fistulous opening situated at the right side of the superior central incisor which was discharging freely a dark-colored pus. On examination, I found the superior right central and lateral incisors and cuspid teeth dead. Patient informed me they had been so for seven years or more, and had never been treated. I diagnosed the case as necrosis superinduced by chronic abscesses. I prescribed the following:

R Acid sulphuric aromatic ʒ ij. 60
Aqua fʒ x. 300
Misce.

To be injected by the patient into the fistulous opening five or six times daily.¹ The patient was also instructed to visit the office every other day for examination.

¹ Bicarbonate of soda and water, used as alkali mouth wash after every injection.

At the expiration of two weeks all discharge had ceased, the soft tissues had fallen into the cavity, made by the chemic action of the aromatic sulphuric acid upon the necrosed tissue. An incision was made extending from the fistulous opening to the right first bicuspid. The cavity was then packed with absorbent cotton saturated with the following:

R Acid carbolic
Tinct. iodin. āā 5 ss. 2|
Aqua. f3 xij. 360|
Misce.

Patient was then dismissed to return the next day, when cotton pledget was removed. The soft tissues having been pushed aside, I was able to see to what extent the bony structures had been diseased. I found the line of necrosis had involved the right facial surface of the superior maxilla from the left central to the right bicuspid teeth and upward from the alveolar ridge to the anterior nasal spine, a part of which with bony structure around the apices of the dead teeth had been destroyed; only sufficient alveolar septum remained to hold them in position.² I opened the nerve canals of the dead teeth and cleaned, disinfected and filled them at once. The filling material was forced through the apical foramina, from the posterior surface, and dressed in the usual manner. The patient was then dismissed with instructions to syringe out the cavity twice a day with the carbolic acid and iodine wash, as long as syringe could be used; afterward the medicament was to be used as a mouth wash. In five weeks new bone-tissue had filled the void, when no suspicion of the parts having been diseased remained, the outline being quite perfect, and all the tissues in a normal condition.

Case 2.—Mr. T., a lawyer, aged 40, of sanguino-bilious temperament, presented the following conditions: A fistulous opening situated to the right of the left inferior cuspid tooth, another to the left of the right inferior cuspid: both openings discharging pus copiously. This condition had continued for over a year, and Mr. T. failing to get any relief from many medications, he consulted a surgeon, who diagnosed his case as necrosis, caused, the surgeon said, by the toxic effect of mercury or syphilis. To either being the cause Mr. T. protested most vehemently. Mr. T. was informed that he would have to be operated upon. The first thing the surgeon suggested was to have all the incisor teeth extracted in the hope that nature would have a better chance to throw off the sequestrum. Mr. T. did not object to having the operation performed, but he did object most strenuously against having his teeth extracted, as he possessed a beautiful set, being perfect in form and arrangement. He consulted me to find out if I could in some way manage to save his teeth. I suggested the sulphuric acid treatment, which I thought would not only save his teeth, but save him from having to undergo any operation. After consulting with the surgeon it was agreed that I should take charge of the case, with the understanding that I was to consult with the surgeon as the case progressed, and not, under any circumstances, change treatment without his knowledge. The treatment in this case was the same as in case of number one. After the first day's treatment Mr. T. came to the office early in the morning with a very distressed countenance, and said he believed I had aggravated the case, because the flow of pus had been so great during the night that he could scarcely sleep. I assured him it was a good sign and that the remedy was doing its work well. The first week the teeth became movable and tender to the touch. A vulcanite splint plate was made to hold the teeth in place and to protect them from shock during the process of mastication. At the expiration of two weeks all discharge had ceased. Then an incision was made from the left fistulous opening to the right, the cavity packed with absorbent cotton saturated with the carbolic acid and iodine mixture (as in first case) and left to remain until next day. When pledget of cotton was removed the following con-

ditions were presented: Line of necrosis found to have involved the facial surface of the inferior maxilla, from cuspid to cuspid, slightly exposing the nerves at the apices of two central incisors. The septa were nearly destroyed, the teeth were only held in position by their attachment to the external or posterior plate of the alveolar process and gum tissue. Same instructions for injection and mouth wash were given as in former case. In six weeks Mr. T. was pronounced cured—teeth all living and firm, and the continuity of maxilla outline fully restored.

I not only received the congratulation of the surgeon upon the successful treatment of the case, but the most grateful thanks of Mr. T. I take no credit for the successful treatment of these cases, but will give all honor and praise to Dr. Gross, of Philadelphia, who, I believe, was the first to suggest the sulphuric acid treatment for necrosis. Some one may ask the question: How does the sulphuric acid act? In reply I will say, that the bony structures of the human organism contains 33 per cent. organic matter, 4 per cent. water and 63 per cent. mineral matter, 60 per cent. of which is carbonate of lime. The action of the sulphuric acid is to seize chemically upon the carbonate of lime, break it down or dissolve it, throwing off carbon dioxide gas; and subsequently the animal tissues, etc., break up through a process of fatty degeneration and flow out in form of pus, etc. The acid in the strength prescribed has no effect upon healthy tissues, except to stimulate them. The advantage of this treatment in the oral cavity over that of operative is: The periosteum is in no way injured, thereby not causing a loss of the continuity of outline of any structures, nor the loss of teeth through the necessary extraction in removal of the sequestra.

Miss G., the first case described, told me not many weeks ago she had not fully appreciated what I had done for her until after she had made a visit to Germany, some three years ago. She informed me of a cousin living in Germany who had a similar case with her own, age the same, conditions about the same, but the treatment and final result quite different. In her cousin's case the teeth involved had been extracted by a surgeon prior to the removal, by operation, of the sequestrum. During the operation the periosteum had been injured, causing a loss of a great part of the maxilla; in consequence her face was disfigured for life. Moreover, she had never been able to have the continuity of outline restored by any artificial means. Now, suppose the two cases I have cited had been treated by operation, in like manner, what would have been the consequences?

In conclusion, I would call the attention of the surgeon, no matter how prone he may be to operate in the oral cavity, not to do so before he has failed in the sulphuric acid treatment, or use more conservative surgery than is usually practiced in similar cases.

THE PROGRESS OF MODERN METHODS IN DENTAL PRACTICE.

Read in the Section on Dental and Oral Surgery at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY ALTON HOWARD THOMPSON, D.D.S.

TOPEKA, KANSAS.

The marvelous success of modern dental practice is founded upon two main elements, viz., *mechanical skill* and *medicinal precision*. In regard to the first named element, mechanical skill, the profession has been noted for that for many years. The best practitioners of fifty years ago were famed for artistic taste

² A similar case is noted by Dr. Black in *American System of Dentistry*, vol. 1, p. 950.

and metallurgic technique, for they produced beautiful work, and which in its way has never been surpassed. So far as mere jewelry work is concerned, there has been but little real advance, but there has been tremendous progress made in the extension of the applications of gold plate work to the purposes of prosthetic restoration. We need only refer to the exquisite gold crown and bridge work, so much in use now, to be reminded of the greatly increased usefulness of this wonderful metal. The rapid development of this work has been the most conspicuous feature of advance of the last decade. It has served to render useful teeth that were in former years condemned to the forceps, and has almost banished partial plates with all their discomforts and injuries, so that this invention has indeed been a great blessing to humanity. Being essentially a new idea; the discovery and perfection of crown and bridge work, has been a great advance, for it was the birth of a great principle in practice; and the promulgations of great principles are the milestones which mark the path of human progress. But crown and bridge work has really been the only thing in which there has been great and positive advance in the last ten years in mechanical work and prosthesis. In plate work there has been little or no great improvement, except in a few minor matters as regards materials or methods; it remains much the same as it was ten or even twenty years ago. The same may be said of operating; there has been little advance, for materials and methods have remained the same and there have been no great discoveries. Some materials, as the cements, have been improved and new appliances have been added to our armamentarium, but no revolutionizing inventions have been forthcoming. We might except porcelain fillings and inlays, but this method is yet very crude and needs to be improved greatly before it can rank as a great addition to our resources.

There has been some improvement in porcelain crown work, but nothing worthy of being called a great advance. While undoubtedly capable of great possibilities, there is urgent need of improvement both of materials and methods. Porcelain is a great material for our uses, but it requires simplification of methods of working before it can have the extended application that it deserves. The prosthesis of the future must be dependent on porcelain or some similar material that will admit of better imitation of the color and texture of the natural teeth, than the metals, that we may keep pace with the artistic demands of the age.

As regards the second element of the successful practice of dentistry in our day, we can safely assert that the greatest general advance in the last decade has been made in the field of medicine, as applied to the treatment of diseases of the teeth and their environments. The greatest positive advance has been in the one feature of the extended application of the principle of antiseptics. The increase of the knowledge of germ life, the growth of the science of bacteriology, and their effect upon the theory and treatment of disease is nothing short of marvelous. We live in the age of antiseptics. Antiseptic medicine and surgery has saved thousands of lives that would have been lost under the old methods. Dentistry has shared in the benefits of the new therapeutics to a wonderful degree. The enlarged usefulness of the profession to humanity in the increased saving of teeth, can not be over-estimated. This is especially true of

the treatment of septic pulp canals and alveolar abscess. Thousands of teeth are now saved that would have been given up at once in the previous decade. Every practitioner now treats and saves scores of teeth that he would formerly have extracted as hopeless. This is a wonderful gain and is a positive advance on the practice of the past. Pulp canal treatment is now performed with scientific precision, thanks to the antiseptic principle. The many antiseptic remedies that have been brought to our notice and that have been useful in various degrees, attest the interest and importance attached to this branch of therapeutics. The treatment of pyorrhea alveolaris has been greatly improved by the use of these remedies and all the advance that has been made has been due to antiseptic medication. Little improvement has taken place in late years in the surgical treatment of this disease, for the thorough removal of deposits was recommended in former years as now, and we have got little further; but we have made vast improvements in the therapeutical treatment and the application of proper remedies. We may safely say that we are now on the road to the successful treatment of this *bête noir* of dental practice, although we have not yet attained the goal. When we shall have reached the precision with which we now treat septic pulp canals and abscesses, in the treatment of pyorrhea, we will have attained another great step in the forward march of progress in dental practice. But it yet defies us and we can not claim that we have made great gains in the direction of overcoming it in the last decade.

In surgical procedure we have advanced to the conquest of new fields, but all we have gained is due largely to the advantages of antiseptic methods and not to any great improvement in operating. The oral surgeon can now attempt more and accomplish greater things than he could ten years ago, but his methods have improved but little. His great success is due to the extension of the antiseptic principle which has done so much for the treatment of all classes of disease in which septic poisoning is present as an important and dangerous factor. Perhaps implantation should be mentioned as one of our special surgical operations, but little has been added to it, either as to its merits or methods during the last decade. Orthodontia is a special branch of practice that might be classed under surgery, or its kindred branch pediatrics, in which great advance has been made of recent years, thanks to the noted specialists who have devoted skilled attention to it. While there have been no great discoveries in the principles there has been vast improvement in the methods of its treatment in the last decade. Deformities are now corrected and reduced that were formerly considered hopeless, and this by the help of scientific knowledge of procedure and by the philosophic application of intelligently designed and skillfully applied appliances.

It is interesting to note the relationship of science to practice in some of the most marked recent advances. True progress involves the application of exact knowledge to the uses of life. Accidental discoveries which have benefited mankind have been made since the emergence from man's previous animal existence and he became capable of the exercise of his distinguishing human faculty, reason. Such discoveries and inventions, be they ever so useful, have been of no extended benefit until illuminated by scientific knowledge of the principles which lie back of them.

and make them possible. With the attainment of this knowledge, discoveries and inventions become clothed with illimitable possibilities. This knowledge has made the great discoveries of the ages the blessings of mankind, printing, steam, electricity, antiseptics; these and more have been made the servants and the saviors of men. Empirical practice is always limited in its application and the good that great discoveries and inventions may accomplish is limited because we are hampered by lack of knowledge of their underlying principles. In the progress of the development of dental practice this is quite apparent. A useful invention or discovery made in an empirical way, is practiced in a limited field for many years with the result of circumscribing its benefits, until some bold investigator, dissatisfied with the mere results without knowing how they are produced, proceeds to experiment and discovers the underlying laws which govern its action. Then it is found that the invention, so useful in one field, could be made of far more general application, and further experimentation leads to the verification of those expectations and its extended usefulness.

It is too true that our art, on which so much of our reputation and usefulness depends, has outstripped our science and this art is largely the result of empirical practice. Take the one item of crown and bridge work, which, while protested against by many as unscientific and pernicious, and it is so in regard to its worst features, yet holds its own and grows because it is practicable and useful. It is unscientific in theory but useful in practice and has sprung from pure empiricism. On the other hand, the other great item of our recent progress, antiseptic medication, has proceeded from pure science, the reasoning from cause to effect, the producing of results from the prediction of discoveries. That is pure science, the producing of practical results from a basis of scientific fact. The mechanical treatment of caries long preceded our knowledge of the real nature of the disease, and the cure attained was the result of pure empiricism and experimentation. The treatment was scientific but it remained for later discoveries to reveal the scientific basis. So with many of our most noted achievements in the conservation of the teeth or their prosthetic restoration; we attained a certain success that was practical and useful but the scientific basis long remained unknown. It was the main characteristic of the old practice that results were reached by the slow process of experimentation, trying first one thing and then another, until something was stumbled upon that answered a practical purpose in a greater or less degree.

The new practice is more scientific. In all its main features it proceeds from a scientific basis. It does not experiment in a blind way but reasons from cause to effect and applies the remedies or appliances that a discriminating judgment suggests as the proper agent for securing a desired result. That is science. The empiric would try what was at hand without regard to its qualities or what he desired to accomplish, and failing in one try another. The success of modern practice depends more on scientific judgment than that of the past, for all of the ordinary possibilities are exhausted. We have gained all the victories within easy reach and to attain more conquests and extend our field of usefulness, we must search deeper and define closer to be enabled to wrest yet other secrets from nature. But that is the motive and the

mission of modern dentistry. We must do yet greater and better things, but to do them we must carry our investigations into untried fields and far deeper into the old ones that we may bring more things to light that will help us to grow scientifically and practically and thereby increase our capacity for service to humanity.

CURE OF PROSTATIC HYPERTROPHY BY INTERNAL PRESSURE.

BY EVAN O'NEILL KANE, M.D.

KANE, PA.

Some years ago I wrote an article for the *Medical Times* of Philadelphia, in which I set forth the superior advantages of internal pressure absorption, as a treatment for senile hypertrophy of the prostate gland with its attendant evils, over the usual forms of palliative and operative procedure. I then gave the credit of this mode of cure, as I do now, to the originator of the operation, the late Dr. S. D. Freeman. The details of the procedure being, perhaps, not sufficiently entered into, my article was received without comment, and, so far as I am aware, it has not led any one to perform the operation. The radical and, it would seem to me, the over-heroic course advocated by Dr. White of the Pennsylvania University, in removing the testicles in order to bring about an atrophy of the gland, if it be a satisfactory cure, entails too great a sacrifice upon those subjected to the ordeal to ever become a popular method of treatment. While the attention of the profession is being attracted to this subject through Dr. White's experiment, I have thought it a fitting time to again point out the merits and method of my pressure treatment. Senile hypertrophy of the prostate gland is not a disease worthy of the surgeon's consideration until its enlargement markedly interferes with the free evacuation of the bladder, as shown by the various disorders, painful, frequent and difficult micturition and the like, incident upon a partial retention of urine. The increased development of the muscular elements in the prostatic organ or muscle becomes harmful only in degree with its encroachment upon the caliber of the urethra by distorting or constricting it. If, therefore, the channel of exit from the bladder can be restored to its normal course and caliber nothing further in the way of treatment is necessary.

The technique of internal pressure treatment is simple, and depends for its successful conduct on a thorough knowledge of the anatomic relations of the parts involved, together with a fair degree of skill in the management of the solid sound and silver catheter. Having determined, by means of a flexible instrument that no stricture exists as a primary trouble, or if there be one, having overcome it, the gland is carefully examined per rectum, in order to ascertain its altered relation to the urethral canal and the precise course of the deviations which have been produced. By means of the index and middle finger of the right hand introduced into the rectum the prostatic gland is steadied and manipulated. A large silver catheter, No. 26 or 28 with an S curve, is introduced along the urethra by means of the left hand, until it reaches the point of resistance. At the same time the fingers in the rectum guide the tip of the instrument through the tortuosities of the prostatic urethra. This manipulation is rendered far less difficult of execution if the beak of the instrument is blunt, as large

as the stem and well polished. Its caliber being large it will be enabled to press the urethra into place ahead of it with far greater ease than if it were small and pointed. It will thus fill the canal snugly. Otherwise the mucous membrane, thrown into loose folds before the advancing instrument will tend to catch upon its point and tear, allowing the urethra to become perforated, a false passage resulting. The structure of the organ being mainly muscular, and its enlargement of a fibro-muscular character it is somewhat resistant. Further, being more or less congested and edematous the impinging portions of the gland are readily displaced laterally by the tip of the instrument, provided a moderate amount of pressure, and a sufficient degree of time are allowed to the maneuver. With patience and gentleness, being careful not to exert undue force, the operator is not likely to be disappointed in reaching the bladder in safety and without injury to the urethra. This step in the operation is the only difficult one, and I repeat, should occupy considerable time, especially if the enlarged gland is dense and hard. The catheter is passed until it rests well within the bladder. Here it is retained by guys fastened from eyelets in its open extremity, extending to a band in the usual manner for retaining urethral instruments in place. A cork is inserted in the open end of the catheter to prevent dribbling of urine, and after the effect of the anesthetic has passed off, the necessary amount of opium is administered to insure quiet. The patient is kept lying upon his back with the knees and shoulders elevated by pillows to a sufficient height to keep the abdominal muscles relaxed. Every four hours he should be turned upon his side, the cork withdrawn from the catheter and the contents of the bladder allowed to discharge. I advise, if the urine is foul and ammoniacal, as it generally is in these cases, that the viscus be washed out daily with warm boracic solution until the odor and cloudiness disappear. The opiate may generally be discontinued by the end of the first twenty-four hours, but should signs of increased irritability of the bladder, or much pain ensue, it must again be resorted to.

The silver catheter should not be disturbed for three days, or at least until it is found that it no longer appears to hug closely the walls of the prostatic urethra. If it is found to glide freely in and out when the guys are loosened it may be withdrawn for an hour with safety. It should then be cleansed, polished and replaced. If not withdrawn too early, or allowed to remain out more than an hour, no difficulty will be encountered in its re-introduction. Each day after the first withdrawal of the instrument, it can be allowed to remain out for a longer period of time, although I advise its retention all night and a portion of each forenoon up to the seventh day, after which time it may be removed entirely. I sometimes find it advisable on account of the resiliency of the prostatic tissue, not to remove the instrument at all, for the entire week. No further surgical treatment is necessary after the final removal of the catheter; all that is required being the administration of ordinary absorbent remedies, such as muriate of ammonia or iodid of potassium for a month or two.

On examination per rectum, it will be found that, while the gland has not yet become appreciably reduced in size, the portions of it which had formerly impinged upon the urethra and diverted it from its proper course have, by the pressure brought to bear upon them by the instrument, been absorbed away, the

urethra appearing to occupy its normal situation. The pressure exerted by the instrument is not only immediately beneficial in its action, by restoring the normal caliber and direct course of the urethra. By its presence within the gland, it appears to set up an alterative, or more properly speaking absorptive action, which, after its withdrawal, is continued until the gland finally assumes its ordinary dimensions.

Pressure treatment of the prostate gland will commend itself to every conservative operator as much superior both to the more brilliant and more dangerous operative methods, and to the various palliative measures which simply have the merit of prolonging life without removing many of the attendant miseries; and there is practically no shock connected with the procedure, not a small consideration in an operation performed only upon middle-aged or elderly subjects. There being no cutting or laceration, there is no danger from the absorption of urine or other septic matter. The benefits resulting from the work done are realized immediately, even before the completion of the cure, and there is less difficulty in persuading nervous elderly patients to submit to a treatment wherein there is no cutting.

I would suggest that were the urethra so tortuous, the gland so enlarged, and its structure so dense as to baffle all attempts to discover per rectum the precise position occupied by the urethra, a modification of the operation might be permissible. This modification, though it would necessitate the use of the knife, would still be safe from the usual dangers incident upon opening the urethra or bladder and the dangers incurred through infiltration of urine. The gland might be cut down upon as in operating for stone, the incision in this case not extending actually into the urethra, but simply sufficiently near to it for the operator to ascertain the position of the tip of his instrument and its relations to the urethra through the wound. This would permit him to guide the tip along the canal to its destination within the bladder with ease. The wound could then be sutured and expected to unite without drainage by first intention, since we would have no urine to irritate and keep it open. The exploratory opening needs only to be large enough to admit the index finger, and deep enough to permit the recognition of the urethra within the substance of the gland.

PERITONEAL SUPPORTS—(LIGAMENTUM PERITONEI.)

BY BYRON ROBINSON.

PROFESSOR OF GYNECOLOGY POST-GRADUATE MEDICAL SCHOOL,
CHICAGO.

(Continued from page 497, Vol. xxv.)

The mesosigmoid is a double right and left-bladed membrane consisting of two serous, polygon-shaped, epithelial-celled layers one on each side, while the middle layer, the essential one, is the membrana mesenterii propria, the real neuro-vascular visceral pedicle. In the membrana mesenterii propria are arranged in definite order the nerves, lymphatics, the arcs and arcades of vessels and the elastic and fibrous tissue bundles which surround and retain in fixed relations the essential structures which maintain the existence of the S-romanum. The nerves which supply the mesosigmoid chiefly arise: 1, from the abdominal brain; 2, from the ganglion at the bifurcation of the aorta, close to the origin of the inferior mesenteric artery; and 3, from nerves arising out of the

lumbar plexus. The inferior mesenteric artery conveys the blood to the mesosigmoidea. The shape of the mesosigmoidea in the adult is very various. It is an unequally S-shaped loop in the human body, in general, and yet there may be in many subjects little in the figure to call one's attention to it. One loop of the S may be very small, or not existing, and the whole of the loop existing in the other loop. Also the S-shaped figure must lie flexible or bent to suit the shape of the dorsal wall. The peculiar shape of the S-iliac is due to three factors: (a), its fixation to the under border of the psoas; (b), to the fixation at the third sacral vertebra (c), to Gruber's fold *i.e.*, to the behavior of the mesocolon as it enters into the neck of the rotating intestinal loop. Gruber's fold is the ligamentum mesenterico-mesocolicum. I designate this duplicature of peritoneum as Gruber's fold, because so far as I am aware, Gruber was the first to describe it. It controls to some extent the mesosigmoid and sustains it from prolapse especially keeping it out of the pelvis. The sigmoid is at first rectilinear. It is situated directly along the mid-dorsal line. It gradually becomes an elongated gentle curve. Finally, it assumes convolutions and lies against the dorsal or pelvic wall. The loop may be in the pelvis, in the right iliac fossa, among the small intestines or rarely on the left iliac fossa. From the tenth week of fetal life its convexity continues to the internal border of the left kidney.

In the evolution of the sigmoid the most notable factor is the left kidney. In the tenth fetal week it is plain to note that the mesosigmoid reaches to the internal border of the left kidney. As the bodily growth progresses the mesosigmoid advances to the interior face of the left kidney and, finally, to the outer border of the kidney as found in adults. The adult position of the ascending colon may be assumed by the eighth to the twelfth week of fetal life, *i.e.*, the descending colon assumes a vertical and may be a sinuous course. It may be noted that old views considered that the sigmoid bowel began at the iliac crest, but modern anatomy starts the sigmoid and ends the descending colon at the external border of the psoas muscle. The upper point of the mesosigmoid often reaches the radix mesenterii and not infrequently the point where the duodenum turns into the jejunum. The whole mesosigmoid may be distorted by inflammations on the lower or left blade, as it lies on the psoas muscle or by old cicatrices on its upper blade especially in Gruber's fold. On account of the variation of the situation and course of the sigmoid and mesosigmoid, it has induced many ingenious views from well-known anatomists. The unequal S-shape to the sigmoid is chiefly due to the length of the ligamentum Gruberii. At the end of the third month the mesosigmoid is generally a lightly curved line reaching from the under pole of the left kidney to the middle of the third sacral vertebra. However, not infrequently the mesosigmoid is quite concave to the left, or the upper point of the mesosigmoid, as it begins to leave the mid-dorsal line, may be pointed to accommodate the intersigmoid fossa formed by the spermatic vessels. In general, at the fourth month the mesosigmoid reaches the fourth lumbar vertebra and then is carried to the left by the lower end of the growing left kidney. If the mesosigmoid be elevated by Gruber's fold during the rotation of the intestinal loop, it will not allow the mesosigmoid to leave the mid-dorsal line so far down. For Gruber's fold may be so con-

tracted by the cecum dragging it upward, as it travels across the abdomen to the under surface, that the upper point of the mesosigmoid may reach as high as the flexura duodeno-jejunalis. Now, since Gruber's fold is attached to the sigmoid at different points, it will induce different sizes to the portions of the S. I have observed that Gruber's fold is frequently attached just below the middle, thus leaving the upper portion of the S the larger. If we look at the upper loop of the S, it will be noted that the sexual gland and the kidney are responsible for it. If we observe the lower loop in its fetal development it may be seen that the sexual gland, later, changes from the lower end of the upper loop and begins to develop that. As time progresses from the fourth month the loops simply grow on slowly. From the sixth fetal month the loops are distinctly pronounced. The sexual gland descends and with the kidney grows rapidly as do the two loops of the S. Meconium now rapidly

fig. 50 represents the line of the mesosigmoid as it crosses the psoas muscle. I sketched this diagram to show how prominent and what an important rôle the psoas plays in relation to the peritoneum and especially in regard to the mesosigmoid. 1, psoas muscle; 2, cut edges of mesosigmoid; 3, descending colon; 4, kidney; 5, cut edge of mesentery; 6, ilium; 7, appendix; 8, right psoas; 9, hepatic; 10, splenic, and 11, gastric arteries; 12, aorta; 13, cut edge of mesocolon-transversum; 14, hepatic flexure. The peritoneum in the region of the pelvis is important to every practicing physician especially in the female. Several years ago I made considerable investigations in regard to the condition of the peritoneum of the male and female and found that in some animals and man the femoral pelvic peritoneum is the thicker and stronger; probably from ages of experiences of peritoneal trauma and repeated infectious invasions. In the region of the pelvis I shall illustrate the peritoneal supports by various cuts, of my own design and also by those of others. The diagrams are drawn not always exact to nature's lines, but nevertheless they approximate some of its truths.

accumulates and irritates the mucous membrane, inducing blood flow and more active growth and elongation of the loop. The loop may grow very rapidly and so elongate that it must seek room in the right iliac fossa or among the small intestines. In one new-born subject Dr. Waite and I found the very long sigmoid rested in the form of a volvulus with the twist situated at the left pelvic brim at the junction of the sacrum and iliac bones. There is a por-

tion of the descending colon extending from the iliac crest to the external border of the psoas muscle which is frequently more fixed than other portions of the vertical colon, but we must consider that it does not belong to the S-iliac. The unnumbered and indefinite classification given to the situation, and periods of development of the sigmoid are of little use, as the situation varies indefinitely, with an organ possessing a long pedicle and no special times of growth. Yet, as to growth, one can note no very especial change in the first two months, but a very decided change in the third and fourth month. One could well say that in the first two months of fetal life, the mesosigmoid is in a primitive condition. It turns neither to left or to right but holds its ancient course in the mid-dorsal line, until the end of the second month or thereabouts. The mesosigmoid is really the old, original primitive mesentery of the digestive tube.

The primitive period may be succeeded by the period of transition from the child-condition to that of the adult. In this period from the beginning of the third month the portion of gut extending from the lower pole of the left kidney to the third sacral vertebra forms two varying loops, an upper and a lower. The two loops are divided by Gruber's fold of peritoneum at first, but subsequently the whole sigmoid may be represented by one large loop. In general the upper loop (*i.e.*, between the external border of the psoas and the fold of Gruber) is at first the larger, but later the lower loop may become the larger loop as the fecal matter accumulates and exercises its irritative and mechanical power. The sigmoid may show a loop in the right iliac fossa, a loop away up among the intestines, a loop in the pelvis and a double loop which lies partly in the right iliac fossa and other localities. Occasionally one can find the double or single loops entirely in the pelvis. During all the stages of transition the line of the root or that of the insertion of the mesosigmoid is generally straightening out, *i.e.*, the radix mesosigmoidea is becoming a shorter line as growth proceeds. The acute angle between the lower mesentery situated in the mid-dorsal line and the mesentery extending from the lower pole of the left kidney to it is increasing and fast becoming a curved line. In short, the root of the mesosigmoid is gradually descending to the adult situation.

A third period of the mesosigmoid may be called the adult period when the mesosigmoid is fixed. It begins at the external border of the psoas muscle and ends in the pelvis at the third sacral vertebra where the rectum loses its posterior serous covering. The loop lies partly extra- and partly intrapelvic. In the adult it hardly ever lies in the right iliac fossa but chiefly in front of the lumbar and sacral vertebra. In the newborn the sigmoid lies chiefly outside of the pelvis from physical reasons. There is but little room in a child's pelvis for any organs except rectum, bladder and uterus. To resume; at first, there is a double loop in the sigmoid, a little later one loop remains in the iliac fossa, the other ascends in the abdominal cavity and the two loops finally coalesce into one large one as it is generally. The great rôle in forming the two parts of the S-loop is done by Gruber's fold. At first it forms the large part of the loop above and the smaller below, but changes and bowel contents gradually make the lower loop of the large, and, finally, the two parts of the S-loop appear as one

inseparable sling. The accumulation of meconium through its irritative and mechanical power is responsible for the large loop and changes from its primitive condition. The situation of the sigmoid at birth may be described as follows: The gut passes from the iliac crest to the psoas muscle, the loop then crosses the pelvis at a level with its brim. It then reaches more or less in the right iliac fossa (20 per cent.), but most frequently simply comes in contact with the right psoas muscle. It then extends, according to its length more or less up among the intestines. The whole S-loop, however, may be in the pelvis in man or woman. The French contend that to do a colotomy on the newborn incision should be made in the right iliac fossa but this proposition will not generally hold true according to my examinations. According to Boucar who examined 150 infants and found the sigmoid loop in the iliac fossa thirty-three times (22 per cent.) There is little utility in describing a descending, transverse, and ascending loop in the sigmoid. The disagreement of authors in regard to the situation of the sigmoid is due to its changing position from emptying and filling with feces and gas from the peristalsis and the changes and situation of other viscera, especially those of the pelvis and its long mesentery. The conditions which determine what organs lie in the pelvis are: (*a*), the size of the uterus; (*b*), the size of the bladder; (*c*), the size of the rectum; (*d*), the size and situation of the cecum; (*e*), the size and situation of the sigmoid; (*f*), the amount of small intestines in the pelvis.

I can see no advantage in the name iliac, or pelvic colons, as neither may correspond to its indicated name or situation. The long mesosigmoid, with its neuro-vascular pedicle, indicates that it has a wide range of motion and that the situation of the loop will be normal wherever the mesentery allows it to range (except where it becomes fixed). Any mobile organ is dislocated when it is permanently fixed. The sigmoid is dislocated when fixed by adhesions or disturbed by a volvulus. In fifty autopsies I found 75 per cent. of adhesions in the mesosigmoid, and volvulus occurs in the sigmoid in 60 per cent., of such cases.

From years of investigations in the abdominal viscera, I would claim that one can only generalize two positions for the sigmoid flexure. The first and most frequent is when the sigmoid flexure lies suspended by Gruber's fold in the pelvis. The second is when the sigmoid flexure lies above the pelvis against the dorsal wall, chiefly to the front of the lumbar vertebrae and to their left. Most other positions of the sigmoid are uncertain, temporary and variable.

(To be continued.)

INTERESTING CASES OF PERINEAL SECTION, WITH REMARKS.

BY G. FRANK LYDSTON, M.D.

PROFESSOR OF SURGICAL DISEASES OF THE GENITO-URINARY ORGANS AND SYPHILOLOGY IN THE CHICAGO COLLEGE OF PHYSICIANS AND SURGEONS; FELLOW OF THE CHICAGO ACADEMY OF MEDICINE, ETC.

(Continued from page 477.)

Case 33: Impermeable Deep Stricture.—A man, 38 years of age, was referred to me by Dr. M. W. Thompson, of Chicago. Had a history of successive attacks of gonorrhea extending over a period of years. Symptoms of urinary obstruction had existed for some four or five years, and had increased until the stricture had become surgically impermeable. I performed perineal section without a guide, found the urethra extremely hard and nodular from the perineo-scrotal junction well down

into the membranous portion. The stricture practically involved the entire extent of the latter. Considering the rather complicated state of affairs the bladder was reached with considerable rapidity, the operation requiring about eight minutes after the opening of the urethra. A small fibrous tumor was found in the right lateral wall of the urethra in the midst of the stricture tissue. This was about the size of a fat pea and was so hard and cartilaginous in consistency that I at first mistook it for a calculus lodged in the urethra at the distal side of the stricture. Several penile strictures required division, one in the scrotal portion of the urethra being especially marked. The urethra was restored to a caliber of 40 French throughout. The drainage tube was removed three days after the operation, and within a short time retention with overflow occurred. For a few hours I overlooked the true condition, inasmuch as the dribbling of urine through the perineal wound was what might have been expected, and indeed what frequently occurs, in cases in which the deep urethra has been widely cut and dilated. Systematic evacuation and the irrigation of the bladder resulted in a complete subsidence of this particular symptom within a week, and the subsequent progress of the case was uneventful. At the present time, two months after operation, the patient takes the 37 French without the slightest difficulty and expresses himself as being in much better health than he has been for many years.

Case 34: Multiple Tortuous Stricture.—Man, about 35 years of age; occupation brakeman. There was in this case a history of repeated gonorrheas, and of possible perineal injury about the age of puberty. The right testis had evidently been the seat of traumatic inflammation and was diffusely enlarged to a moderate extent and quite hard. This condition, he said, was the result of an injury which, as near as he could recollect, also involved the perineum. He had not had, however, any urinary symptoms until within the last year. About a year before consulting me he had noticed that the stream of urine was growing gradually smaller, and that it took some time to empty his bladder. He was otherwise in perfect health. Examination revealed a tortuous stricture extending from the fossa navicularis to the peno-scrotal angle. This admitted a No. 10 French. At the bulbo-membranous junction, in obstruction was encountered through which I at first found it impossible to pass a filiform bougie. Complete retention did not occur. The patient succeeded with considerable effort and expenditure of some time in emptying the bladder sufficiently to afford relief at least. At the end of about a week I succeeded in passing a filiform bougie, and within a few days I succeeded in dilating the deep stricture to a caliber of No. 7 French. The stricture, however, now proved absolutely resistant to treatment, and no further attempts at dilation developed urethral chill. Inasmuch as this condition of affairs was associated with penile strictures, which would probably demand a radical operation, I deemed it wise to perform perineal section. The operation in this case was free from difficulty, but the subsequent course of the case was a little annoying. There was no fever or other untoward symptom following the operation, but the perineal wound healed only in part, the anterior angle remained open and affording an excellent prospect for a permanent fistula. At the end of six weeks I found I could pass a No. 36 French into the bladder without any difficulty, but the fistula showed no signs of repair. I cauterized the small opening with tincture of iodine applied in liberal quantities, a sound meanwhile being left in the urethra. I now passed a single strand of silkworm gut and anchored it with shot. No catheter was introduced into the bladder, the patient being allowed to pass his urine as though no fistula existed. To my gratification the fistula was soundly healed at the end of a week, and not one drop of leakage occurred after the shot suture was introduced.

Case 35: Supra-Pubic Fistula; Multiple Perineal and Penile Strictures of gonorrheal origin: Use of the Retrograde Guide.—Young man, 25 years of age; occupation bookkeeper; history of successive attacks of gonorrhea, first attack having been experienced at the early age of 14. This patient was always very delicate, and his urinary trouble had been very poorly tolerated. Urinary obstruction was first noted four years before I first saw the case. The patient was dissipated and suffered from severe attacks of retention, which were evidently due to congestion and spasm superinduced by excesses. The last attack of severe retention had come on the year before I saw the case. The practitioner who was called in, failing to introduce an instrument per urethram, decided within twenty-four hours to pass a trocar supra-pubically. This was accordingly done with a small retrograde catheter introduced through the trocar. A permanent fistula remained. Numerous attempts were afterward made to enter the bladder with bougies, but

without success. At the time the patient consulted me he was under the impression that the urethra had, as he expressed it, entirely grown together; but that he was so greatly annoyed by the supra-pubic fistula that he was anxious to undergo almost any operation to secure relief. The operation in this case was simplified greatly by the fact that a supra-pubic opening already existed. This was enlarged sufficiently to introduce the finger for the purpose of guiding a flexible bougie of good size into the posterior urethra. The penile urethra was so tightly strictured that it was with great difficulty that a filiform could be introduced down to the perineal portion of the canal. Careful dissection in the perineum enabled me to open the urethra just anterior to the bowel, at which point the canal was not greatly narrowed. The subsequent steps of the operation were very easy, there being no difficulty in finding the posterior portion of the urethra with the assistance of a retrograde guide. I made the attempt to close the supra-pubic fistula by suturing the bladder, when a small opening remained with moderate leakage for about three months, at the end of which time the supra-pubic wound was soundly healed. The penile strictures were cut to a caliber of No. 32 French, a sound of this size being readily passed into the bladder. The patient was last heard from two years after the operation, at which time he was passing No. 30 French without difficulty, and was apparently perfectly well, his general health having markedly improved.

Case 36: Deep Perineal Stricture of Gonorrheal Origin, Complicated by Hypospadias.—Man, 30 years of age; occupation, traveling salesman; singular type of gonorrhea acquired at the age of 25. This had continued with occasional exacerbations, with periods of improvement due to reinfection or otherwise. Urinary obstruction had developed two years previously. Attempts at treatment by dilatation had apparently been harmful. There had been no attacks of retention, but the obstruction to micturition had progressively increased until the patient found it almost impossible to evacuate the bladder and there was, the greater portion of the time, constant dribbling of urine. Examination in this case revealed a complicated condition which proved very annoying; there was a moderate degree of hypospadias, the meatus opening about one-fourth of an inch posterior to the glands. This opening was very narrow and would not admit a sound larger than a No. 8 French. After several sittings I succeeded in passing a filiform into the bladder, but the urethritis increased to such an extent that I hardly felt justified in depending upon the repeated reintroduction of instruments. Complete closure of the stricture from the reactionary inflammation seemed probable. I therefore suggested a perineal section, which was consented to. The pseudo-meatus was enlarged transversely, the penile urethra being found to be free from obstruction. The perineal portion of the canal was quite extensively strictured, the obstruction extending as far forward as the perineo-scrotal angle. The stricture in this case was not well developed, consequently I did not consider it wise to incise as freely as I would otherwise have done. The urethra was therefore enlarged to a caliber of only 30 French; a sound was passed on the fifth day after the operation without difficulty. Instruments were reintroduced at intervals of three or four days for about three weeks, at which time it was found that they could be passed with great difficulty. A week later it was found impossible to pass a sound larger than No. 20 French. I therefore suggested reopening the perineal wound, with division of any contracting bands which might be discovered. I found, on reopening, that the incision made in my first operation was not sufficiently free, a bridge of cicatricial tissue having reformed on the roof of the canal at about the middle portion of the urethra. This was freely divided, the remainder of the canal apparently not requiring attention. The favorable course of the case after the second operation was uninterrupted.

Recontraction had not occurred at the end of six months after the dismissal of the case.

Case 37: Multiple Penile and Perineal Strictures of Gonorrheal Origin; Perineal Fistula from Previous Operation.—Man, 40 years of age; occupation, hardware merchant. This patient had a history of numerous attacks of gonorrhea, the first of which had been experienced at the age of 20. At the age of 35 stricture developed with a progressive obstruction to micturition. Complete retention finally occurred, and two years before I saw the case he had been operated on during an attack of retention. The operation was evidently not thorough, the operator contenting himself with the relief of the retention. Several penile strictures were not interfered with. After the operation sounds of small size were passed for a time, and it was finally found to be impossible to introduce anything larger than filiforms down to the site of the operation. The

fistula remained open. I succeeded in passing a filiform from before backward, bringing it out at the perineal opening. Upon this filiform I tied a strong silk ligature entirely through the urethra and out of the perineal wound. I now tied a No. 4 bougie upon the end of the ligature emerging from the meatus, and drew it down through the perineum. Using this as a guide I divided the perineum thoroughly, found the urethra was free posterior to the fistula, but that it was tightly contracted at the peno-scrotal angle. I divided the stricture upon the roof of the canal by means of a blunt-pointed bistoury, and had no difficulty in introducing a urethrotome and dividing the penile strictures. The urethra in this case was very large, and after the operation I had no difficulty in introducing a No. 40 French into the bladder. The case progressed nicely with the exception of the perineal wound at the site of the old fistula, which was very stubborn in healing. Finally, however, by repeated use of the shotted sutures and applications of iodine I succeeded in closing the opening. This case has not been heard from since three months after the operation, at which time a No. 30 French could be passed with great ease.

Case 38: Intractable Traumatic and Multiple Inflammatory Strictures.—Young man, 25 years of age, referred to me by Dr. Gfroerer, of this city, for the relief of a very tight stricture at the perineo-scrotal angle. Exploration showed several strictures of varying caliber in the penile urethra. The young man gave a history of severe traumatism, sustained some years before, and of several subsequent attacks of gonorrhea. Considerable damage was done to the urethra by the original perineal injury: retention of urine occurred at that time, for the relief of which an attempt was made to pass a catheter with the result that the floor of the urethra was completely perforated and the catheter pushed entirely through the crushed perineal tissues. Perineal abscess and fistula followed. Numerous attempts at a cure of the resulting stricture had been made, including the use of the permanent catheter for weeks at a time and several internal cutting operations. As the gentleman who referred the case to me had not performed any of the operations mentioned, I was unable to obtain accurate data. I proposed perineal section, and the operation was accordingly performed. It was with extreme difficulty that I succeeded in getting a guide through the stricture even under anesthesia. I finally succeeded in introducing a small filiform. The operation showed a dense cicatrix involving the urethra at the perineo-scrotal angle. The perineal fistula, which was still present, showed a line of dense cicatricial tissue running along the urethral wall, the stricture and the indurated fistulous track being intimately blended together. The urethral tissue, which was present at the point of stricture, was so slight in extent that grave doubts existed in my mind as to the ultimate success of the operation. The perineal urethra was restored to a caliber of 38 French. Although the penis in this case was extremely small and apparently undeveloped, no trouble was experienced in enlarging the entire extent of the urethra to the caliber mentioned. The patient did fairly well after the operation, a full-sized sound being passed in the usual manner. Four weeks after convalescence was thoroughly established, recontraction of the stricture began and progressed with extreme rapidity. The patient being willing to undergo a second operation, perineal section was again performed. The penile urethra was found still free from contractions and the perineal stricture had recontracted only at one point, involving the narrow extent of the urethra at the site of the original injury. At this operation I divided the urethra completely through upon the roof and had no difficulty without any further cutting of the penile urethra in introducing a 40 French into the bladder. Two days later I grafted a piece of integument from the outer surface of the patient's thigh upon the roof of the urethra at the site of the stricture, with the result that a small portion of the transplanted integument adhered. The operation was performed early in January. It is now two months since the second operation, and although sounds have been regularly introduced at intervals of from four to seven days, recontraction is beginning again. Recontraction, however, seems to be entirely upon the floor of the canal, the point at which the graft was made seemingly being still perfectly smooth and supple. It is impossible to say at the present time to what extent recontraction will occur. A 33 French can be introduced at the present time, and if recontraction does not progress to an extent sufficient to seriously obstruct the passage of urine, and if it should be possible to maintain a moderate degree of patency of the canal, I shall consider that the operation is a brilliant success. In case further operation becomes necessary, resection of the involved area of the urethra is to be taken into consideration. But I am free to say that I believe that that particular method of operating will in this case be rather difficult,

and it is possible that it may yet become necessary to establish a permanent artificial urethra in the perineum.

Case 39: Impermeable Perineal Stricture with Multiple Fistulae: Suprapubic Cystotomy and Retrograde Catheterization.—Man, 40 years of age; occupation clerk. This man stated that he could hardly remember a time since he was 16 years of age that he did not have a gonorrhea of greater or less severity. His first urinary trouble began at the age of 30, at which time he was said to have a stricture. He was treated by sounds at intervals for several years. About five years after symptoms of stricture first developed he had an attack of retention which was relieved by catheterization. Instrumentation at this time was apparently rough and resulted in the development of perineal abscess. This was opened and found to communicate with the urethra. A succession of abscesses formed, with the formation of numerous sinuses and fistulae, several of which burrowed well out upon the buttocks. One sinus had evidently burrowed backward, involving the ischio-rectal fossa, at which point an abscess had formed with a resulting urinary fistula. The patient was in a fair condition generally, and there was no immediate danger of retention. He was carefully prepared for an operation for one week, at the end of which time perineal section was performed. After prolonged search for the urethra and perineum, a search which was attended with considerable hemorrhage, I decided to open the bladder above the pubes. The passage of a retrograde guide enabled me to find the proximal portion of the urethra with great facility. The sinuses and fistula were laid freely open with the urethra freely divided on its roof. The urethra was restored to a caliber of No. 35 French, with division of several strictures of greater or less caliber in the penile urethra completing the operation. Through and through drainage was instituted in this case, and a considerable degree of cystitis existed, so that I had little hope of obtaining primary union of the suprapubic and vesical wound. At the end of one week the drainage was made entirely perineal. At the end of four weeks both the stricture and perineal wounds were soundly healed, several sinuses and fistulae, which had been laid open, not being entirely cicatrized. I had the opportunity of examining this patient three years later, at which time he was perfectly well and could pass a No. 30 French with no particular difficulty.

Case 40: Deep Stricture of Gonorrheal Origin; Reoperation.—Man, 45 years of age, engineer. This patient had suffered from numerous attacks of gonorrhea and had developed stricture about the age of 35. He had had numerous attacks of retention, which at first were relieved by catheterization. The stricture finally, however, became impermeable, when perineal section was performed. A fistula followed the operation, which lasted eight months and finally closed. In spite of the advice of his surgeon, the patient had neglected instrumentation, when an attack of retention came on which was relieved with great difficulty. Patient finally consulted me, and I found multiple tight penile strictures, in addition to an old perineal stricture which had closed so tightly that I could not introduce a filiform. The penile strictures may or may not have existed at the time of the previous operation, but the patient could give me no information on this point. He was anxious to have something radical done for the relief of his condition. I performed perineal section without a guide. The urethra in this case was restored to a caliber of No. 36 French, the penile strictures being freely divided. There was a chill followed by slight rise of temperature on the third day after the operation, temperature remaining slightly elevated for nearly a week, at the end of which time it became normal. The perineal wound was closed at the end of two weeks; the patient was allowed to get up and about a few days later. I have not heard from this patient since the operation. I have provided him with the necessary sounds, and he was thoroughly appreciative of the necessity of their occasional introduction. I have little doubt that the ultimate result was good.

Case 41: Recent Deep Traumatic Stricture.—Man, 27 years of age, electrician by occupation; referred to me by Drs. P. M. Woodworth and C. A. David. Three months before consulting me this patient fell astride of a joist while working in a building. He suffered severe contusions in the perineum and buttocks, and was confined to his bed for three weeks. For the first week or ten days catheterization was necessary, after which time the urethra was left to take care of itself, with the result that within two months it had almost entirely closed. Micturition was frequent, with straining, and the urine extruded *guttatim* with great difficulty. The patient was otherwise in excellent condition and denied venereal history. I found it impossible in this case to introduce even a filiform guide, the urethra having been so extensively lacerated and encroached upon by cicatricial deposits. Perineal urethrotomy

was performed, and the urethra enlarged to a caliber of No. 40 French. Incision of the meatus being necessary, I introduced an instrument of its size. The penile urethra was found perfectly clear; the perineal wound was consolidated at the end of two weeks, and at the end of six weeks the patient was dismissed. When last seen, three months after the operation, he was passing sounds from 32 to 35 French with great facility. He had regained his health. Recent advices from this patient show that he is still in excellent condition.

Case 42: Deep Stricture with Multiple False Passages.—Man, 38 years of age, hardware merchant by occupation. This man had been a patient of mine before; I operated on him some five years previously for empyema of the gall bladder and cholelithiasis. He had at that time symptoms of stricture and I advised him to give the matter some attention, but the condition for which I operated was so predominant in his mind that he considered the urethral trouble a minor matter. The first intimation of urinary obstruction occurred about the age of 30, he having had several attacks of gonorrhea. The recent acute attack at that time brought on retention. This was relieved by simple measures, but recurred from time to time, and was relieved by catheterization. He had been treated at irregular and spasmodic intervals by dilatation, but with only temporary relief. He had never, he stated, given the various surgeons whom he consulted a fair chance to cure him, and he ceased treatment as soon as he felt a little better. During some of the attempts at catheterization with a view to relieving these numerous attacks of retention, several false passages were made. I found it impossible to introduce even a filiform into the urethral tract on account of the size of the openings and false passages thus formed. Every attempt at instrumentation produced chills and fever. I performed perineal section and found the operation a most difficult one, requiring some time to discover the course of the urethra. Considerable hemorrhage from small vessels was encountered, which necessitated very careful packing of the wound with solid rubber drainage at the completion of the operation. The patient did well. There were slight chills and moderate fever for a few days after the operation. This, however, subsided and the case went to a rapid recovery. By the operation the urethra was restored to a caliber of 35 French, and a caliber of 32 French was permanently retained. It is now three months since the operation and the patient is in excellent condition.

Case 43: Deep Penineal Stricture of Gonorrheal Origin: Multiple Penile Stricture.—Man, 30 years of age; occupation, captain of a small sailing vessel. This man gave a history of previous attacks of gonorrhea and of symptoms of stricture dating back five years. The necessity for careful attention to the stricture had been impressed upon him by several capable surgeons, but on account of his occupation he found it impracticable to follow their advice. The stricture gradually diminished in caliber, with resultant increasing obstruction to micturition. An attack of retention coming on after a drunken bout, while he happened to be on shore, compelled him to seek surgical advice. There was no marked difficulty in introducing a small catheter in this case, but the peculiar circumstances of the patient, and the danger of subsequent attacks of retention induced me to suggest perineal section. A small guide was readily introduced and the stricture divided with great ease. The urethra was restored to a caliber of 35 French, meatotomy being necessary. The perineal wound was practically healed at the end of a week, at which time the patient was passing urine in the natural manner with the greatest possible comfort. He was dismissed at the end of three weeks, and provided with sounds necessary to keep up dilatation. When last heard from, three months after the operation, he had had no further trouble with his urinary organs.

Case 44: Deep Traumatic Stricture Complicating Prostatic Abscess; Prolonged Retention.—Man, 33 years of age; occupation, engineer, consulted me for retention of the urine which had lasted for thirty-six hours. There was a history of numerous attacks of gonorrhea, the first of which occurred ten years before. Symptoms of stricture developed some five years previously, and since that time the patient had been treated at irregular intervals by dilatation. He had never had an attack of retention until the one for which he consulted me. Some six weeks before I saw him he was induced to try electrolysis for his old stricture, which was again troubling him. The result was apparently a prostatic inflammation, and absolute failure as far as relief of the stricture was concerned. I have no criticisms to offer upon the application of electrolysis in this case, as have no means of knowing whether it was properly or improperly applied. I will simply state the history as it was presented to me. On examination I found a large peri-prostatic abscess bulging into the rectum,

and apparently almost ready to rupture. The patient's temperature at this time was 104 Fahr., and he was in a profoundly asthenic condition. The indications seemed to me, however, to be perineal urethrotomy by means of which the abscess above the prostate could also be drained. In accordance with this idea the operation was performed, the urethra restored to a caliber of 35 French. The posterior portion of the incision in the perineum was carried quite deeply, the knife being thrust boldly in after the fashion of Cock's operation, and the peri-prostatic abscess was reached without difficulty. The operation was done without a guide, it being found impossible to introduce one into the bladder. The cavity of the abscess was packed lightly with a strip of gauze, and the usual perineal drainage was instituted. Several slight strictures were divided in the penile urethra, a meatotomy being found necessary. Within three days the temperature had fallen to normal, and aside from the rather slow healing of the sinus left at the posterior portion of the wound, communicating with the abscess, the subsequent course of the case was all that could be desired. The patient was passing his urine entirely per urethram at the end of ten days, but it was nearly three months before the sinus alluded to was closed. This patient has just been dismissed from my charge. Four months after the operation a 32 sound passes readily into the bladder.

Regarding the rôle of electricity in the production of the retention, I will state that at the time when I was endeavoring to test the merits of electrolysis in urethral stricture I had a somewhat similar experience. The retention, however, was relieved by simple measures within twenty-four hours. The stricture in this case was of comparatively large caliber.

Case 45: Deep Linear Stricture of Large Caliber of Gonorrheal Origin; Chronic Prostatitis.—Man, aged 35; clerk by occupation. This patient gave a history of repeated attacks of gonorrhea, the last of which occurred two years before I saw him. Acute prostatitis occurred as a complication of the last attack, and he had been annoyed since that time with an obstinate attack of gleet, with frequent exacerbations of subacute urethritis. The vesical neck remained excessively irritable, and for a few weeks an exacerbation of inflammation of the deep urethra or of the prostate was experienced, with resulting frequent and painful micturition. From time to time the urine contained a small amount of blood. All attempts at deep irrigation, or the passage of instruments, aggravated the trouble. Several surgeons who had examined the case pronounced it one of prostatic and vesical tuberculosis. The patient was thin and worn and had been excessively annoyed by the loss of sleep incidental to frequent micturition. Considerable pain in the back was complained of, and from time to time urinary fever developed, this being invariably the case after attempts at instrumentation of the urethra. The anterior urethra was exceedingly sensitive and was the seat of several strictures of moderately large caliber. Careful examination with the rubber exploring bulbs revealed a linear stricture of large caliber at the bulbo-membranous junction. In view of the condition of the prostate and the vesical neck, and the resistancy of the case to ordinary treatment taken in connection with the tendency to urinary fever, I believed that the combined internal urethrotomy and perineal section with prolonged bladder drainage offered the only reasonable prospect of a cure. The operation was accordingly performed, the urethra restored to a caliber of 35 French. Internal urethrotomy was performed upon the penile strictures and the deep stricture divided via the perineum, very little cutting being necessary to accomplish this end. The posterior urethra was thoroughly dilated and bladder thoroughly explored with the finger, nothing, however, being found. Drainage was kept up via the perineum for three weeks, during which time the patient was perfectly comfortable. The patient was discharged at the end of the fifth week. It is only a few weeks since the patient was dismissed, hence it is hardly fair to form conclusions as to the result. I will state, however, the patient is at the present time perfectly comfortable; has risen but once at night, and urinates about once in three hours during the day time. There is no doubt in my mind but that this patient will perfectly recover.

Case 46: Penile strictures; Reflex Vesical Irritation; Posterior Urethrotomy.—Gentlemen, 45 years of age, consulted me regarding vesical trouble which he had for ten or more years. He recognized the source of his difficulty as a gonorrhea contracted at the age of 30. Some five years after the gonorrhea he developed symptoms of stricture, frequent and painful micturition, a slow and sudden intermittent stream of urine being the principal characteristics. He had been treated in various ways. It was thought at one time that he had a stone and an exploratory supra-pubic cystotomy was performed with the result that no stone was found. Irrigations and topical applications of silver to the deep urethra seemed to aggravate

the condition. The contracted meatus had been slightly cut without any relief. At the time he consulted me the urine was normal, with the exception of a few shreds indicative of chronic urethritis, both the anterior and deep urethra being involved. Micturition occurred seven or eight times at night, and as the patient expressed it, "every few minutes during the day time," considerable effort being necessary to expel the urine, the stream being suddenly shut off several times during the act. This spasmodic shutting off of urine was attended by considerable pain. The patient was markedly neurasthenic, but his general nutrition was fair. Exploration of the urethra revealed three exceedingly irritable penile strictures of large caliber, and the meatus, which, in spite of a meatotomy which had been performed, was considerably contracted.

This case was a type of many which have come under my observation, and the patient's condition seemed obviously the result (1) of reflex irritation from the penile strictures, and (2) from infection extending back from the posterior surface of these strictures. I proposed internal urethrotomy and suggested the advisability of making a perineal section. Thinking there might be a linear band of contraction at the bulbo-membranous junction, and believing moreover that a couple of weeks' drainage and rest for the bladder constituted an important indication, I therefore performed both internal and external urethrotomy. I found the membranous urethra contracted and thickened with chronic inflammation with a large calibered linear stricture at the bulbo-membranous junction. The after-course of the case was uneventful. Drainage was kept up via the perineum for two weeks, at the end of which time the tube was removed and the wound allowed to close. The subsequent course of the case was most gratifying, the patient being now, four weeks after the operation, in excellent condition, rising at night only once to micturate, the act being performed only five or six times during the course of the day. There seems to be a progressive tendency to improvement, and I am perfectly confident that a complete cure will result. The urethra will now admit a sound of caliber of 36 French, although it will not be necessary to maintain the patency of the canal at this standard.

Case 47: Deep Stricture of Gonorrheal Origin with Recurrent Urethrorrhagia.—Man, 32 years of age, bookkeeper by occupation, suffered from a deep stricture of gonorrheal origin. This had been detected some seven years before I saw the case, and had been variously treated by dilatation, electricity and applications of nitrate of silver, etc. The patient stated that from time to time, usually precipitated by intercourse, he had quite free hemorrhages from the urethra. This symptom, he stated, was the most annoying of any that he experienced, and was the one which led him to seek more radical measures of relief than had hitherto been adopted. On examination I found an irritable resilient stricture of large caliber at the bulbo-membranous junction with three distinct coarctations of large caliber in the penile urethra. The exploration brought on very profuse hemorrhage, and it was attended by severe pain. Some days after my examination the patient suffered from quite sharp attack of inflammation of the vesical neck and prostate, this finally being allayed by cautiously attempted treatment by dilatation, the result being a repetition of my previous experience. After three disagreeable experiences of this kind I decided to perform perineal section. I performed internal urethrotomy for the anterior strictures and made a free division of the strictured band in the deep urethra by the external section. The urethra was restored to a caliber of 35 French. It is worthy of note that the hemorrhage at the time of the operation was trivial. I, however, packed about the perineal tube, as a matter of routine, iodoform gauze necessitated by the hemorrhage. The perineal tube was removed in this case on the third day, there being to my mind no necessity for prolonged drainage. Sounds were passed the first time on the fifth day, dilatation being repeated every third day thereafter. Patient was up and about at the end of two weeks, and was discharged at the end of the third week. It is now one month since the patient was discharged from my care, and he is in first-class condition. He has not performed the experiment of sexual intercourse to determine whether the hemorrhage will again occur, but from the facility with which large sound can be introduced, there is no question in my mind but that the operation has resulted in a perfect cure.

Case 48: Deep Stricture of Gonorrheal Origin. A young man, 25 years of age, consulted me regarding a tight stricture of the deep urethra which had existed for three or four years. There was no history of traumatism, and the patient was in doubt as to ever having had a genuine attack of gonorrhea. An obscure history, however, of slight discharge at about the age of 17, which discharge lasted for a year or more, made the case sufficiently plain. There was no special indication for radical

operation in this case, as far as the merits of the stricture itself were concerned, for the stricture appeared readily dilatable, as shown by a week's continuous, followed by intermittent, dilatation. The patient was unable to remain in the city for a sufficient length of time to accomplish much, and was therefore desirous of having a radical operation performed. I did an external urethrotomy, which was devoid of interesting features. The case was an easy and simple one. It has been only two weeks since the operation was done; the patient is about ready to return to his home and the urethra admits with great facility No. 33 French.

Case 49: Deep Gonorrheal Strictures with Multiple Fistulae.—Man, 45 years of age, stockman; had experienced a number of attacks of gonorrhea, none of which had occurred within ten years. There was also a doubtful history of traumatism. Various attempts at treatment by dilatation had been made with temporary relief. Peri-urethral abscess had developed some years before I saw the case and had left several fistulae, one of which involved the scrotum. The history of urinary obstruction dated back some fifteen years. For some time the patient had been rapidly failing in his general health. Attempt at exploration had been followed by chill and sharp "urinary fever." Urinalysis revealed nothing definite regarding the condition of the kidney, but more or less advanced disease of these organs was taken for granted.

After careful preparation by dieting, baths and the administration of urinary antiseptics, perineal section was performed, operation without a guide being necessary. Ether was the anesthetic used. All sinuses were carefully followed out and laid freely open. Hemorrhage from small vessels was unusually profuse, necessitating the Paquelin cautery at some of the deeper points in the divided sinuses and fistulae. The urethra was found only after prolonged search, and at the completion of the operation the patient was greatly exhausted. He reacted fairly well, however, the urethra admitting 32 French and the perineal wound having closed, when two weeks after the operation anuria developed, uremia followed and death occurred within forty-eight hours.

Autopsy revealed a good condition of the operative field. The kidneys were pyelo-nephritic and showed evidences of recent acute congestion. I will remark in this connection that death in such cases is often superinduced by the anesthesia, even where chloroform is given, but especially when ether is used, but the fatal result occurs so long after the operation that the real cause is overlooked. I desire to insist on this point, because we are often unfair to chloroform. The latter drug declares itself in speedy and unequivocal fashion as a rule, while ether often destroys life so remotely that the true cause of death is lost sight of.

(To be continued.)

SELECTIONS.

The Present Status of Animal Therapeutics.—By F. KRAUS.—Manufacturing chemists are constantly producing new remedies, and scientists the world over are seeking specifics for the ills of man. But medicine in our day has certainly inaugurated a new era in the treatment of the parasitic infective diseases of which Behring's antitoxin is the most brilliant success so far. Another branch of it is the new "organ extract" or "animal" therapeutics, which is essentially a modern idea, although there is a suggestion of it in Galen's castoreum, and also in Pliny, where we read that the Romans ate the testes of asses in cases of impotency.

It is based on Brown-Séquard's and Bernard's theory of an "internal secretion" accompanying the external secretions of different glandular formations. The absorption of this internal secretion leads to the formation of important specific products. Bernard was led to this conclusion by observing the production of glycogen in the liver and comparing it with the secretion of gall. The list of organs that perform this function of an internal secretion, according to the latest theories, includes the pancreas, the supra-renal capsules, which seem to have the power to render innocuous certain poisons that develop in the body, the thyroid glands and perhaps also the hypophysis cerebri, the testes, the ovaries and the kidneys. In 1889 Brown-Séquard applied this abstract fact to practical medical use. He announced that the testes supply certain elements to the blood

which impart renewed energy to the nervous system, and in all probability, to the muscles also. Associating D'Arsonval with him in his researches, they soon announced this theory that all the tissues and organs of the body, non-glandular as well as the glandular, secrete specific substances, so that any failure in the function of any special tissue or organ may result in serious organic disturbances. From this theory came the proposition to supply to the organism the fluid extract of a healthy organ to substitute the lacking function of the diseased organ. Among all the numerous attempts to carry this proposition into execution, the administration of the extract or dried tissue of the thyroid gland has been most carefully studied and produced the most notable results. No one longer doubts that the thyroid gland has actually a specific function, since this was established by the experiments of Schiff, Hoehner and Horsley-Semon. Another fact settled is the pathologic identity of cachexia and tetania thyreopriva, of idiopathic myxedema and true thyreopriva cretinism, which are now all classified as cachexia thyreoidica. There is also every probability that exophthalmic goitre and what is called status lymphaticus, and even acromegaly, will be found to be intimately related to the processes of the thyroid glands. We assume to-day that the function of the thyroid gland is to change or destroy certain substances which circulate in the blood and are injurious to the organism. This is called the auto-intoxication theory. In addition to this, the gland performs an important secretory function. Another theory proposed by some, is that these glands secrete a substance of great importance to the growth of the bones, muscles and nerves, and indispensable to the vital processes of the organism. In time these two theories may be found to harmonize into one. Our present morphologic knowledge favors the assumption of this idea. The epithelial cells of the thyroid gland form a wall around the entirely inclosed little pockets of the gland, which are filled with a peculiar, jelly-like or colloid substance. Between these follicles are placed the nerves, the blood and the lymph vessels. This colloid substance is also found in the lymph passages between the pockets. The capillaries are intermingled with the epithelial cells, in some cases even boring into them. Changes in the epithelial cells testify to the fact that they secrete a specific substance. Hürthle distinguished one secretion accompanying growth of the follicular epithelial cells, and another as they degenerated. In the former, what Langendorff calls the colloid cells, are principally involved. This is the first secretory change of the cells in the protoplasm visible to the eye, and yet the secretion accompanying degeneration is the preliminary which makes the other possible, as it precedes subdivision. The protoplasm degenerates and flakes off from the wall of the follicle and mixes with its contents; the follicles pass it along from one to another and into the lymph passages. This dissolution of the epithelial cells is a necrosis inseparable from the vital processes of the organism, and accompanying it, is a special secretion. The process of secretion in the glands is not under the control of the nervous system. The stimulus is imparted by a certain state of the blood. Hürthle has reported certain observations and experiments which directly confirm this theory. One proof of this is seen when the biliary duct is tied and jaundice thus produced; a simultaneous secretion of colloid substances occurs in the thyroid glands, of great intensity, appearing in the colloid cells, the lymph passages and even in the epithelial cells, which did not normally occur. This secretion works its way from the follicles into the lymph passages of the gland either by disintegration of the follicular wall as Biondi believes or through the spaces between the cells, according to Hürthle. These spaces open up when required, but have no permanent character. Whether the colloid substance is then taken directly into the blood or not is still unsettled; in any case it soon finds its way into it somewhere. The thyroid gland and

the suprarenal capsule are the only glands yet discovered in which the transmission of their secretions directly into the blood has been watched and followed by the eye. As yet we have unfortunately no chemical proof of this specific substance. Mucin, or something resembling it, is found in the skin and tissues, in the gastric juice, etc., of patients suffering from idiopathic myxedema, but not in the quantity nor with the regularity we might expect if we accept Horsley's theory that mucin is formed in the tissues to a toxic extent when the thyroid glands fail in their regular functions. The results of Wagner's and Hammerschlag's experiments, injecting mucin into a cat and producing tetanic symptoms, are still waiting for an explanation. Experiments with dead thyroid gland substance on animals, and also on normal and diseased human beings, as well as the thyroidectomy operated on diseased persons, all tend to confirm the theories advanced above. Numerous experiments with normal and goitrous persons also seem to demonstrate the fact that the normal thyroid gland plays an important rôle in controlling and distributing the phosphoric acid in the organism. When this gland fails in its functions, the processes of growth in the bones and nervous system are disturbed because they miss the phosphoric acid necessary to them, or perhaps receive too much of it. If the gland is abnormally extreme in its functions, then P_2O_5 diabetes results, with a lack of phosphoric acid throughout the body. The functions of the thyroid gland are apparently more important to the organism during its development than after maturity. It is in proportion to the total weight, far larger in the newly born. Experimental thyroidectomy is far more fatal in young animals, and in human beings over 30, cases of cachexia following removal of a goitre are almost nil, while before puberty cachexia is an inevitable consequence. Gley and Christiani have asserted that accessory organs can carry on the functions of these glands when necessary; and since Lesas announced that there was a compensatory hypertrophy of the spleen when the thyroid gland was removed, this theory has been coming to the surface again and again. But more recent researches prove that this is a mistake. Albertoni and Tizzoni, and also Gley have found that cachexia does not occur any sooner in animals whose spleen has been removed, than in others with a normal spleen. De Quervain has studied with particular attention the action of the spleen in cachexia thyreopriva without finding any vicarious hypertrophy at any stage of the disease. Examinations of the spleen after death in five cases of strumipriva cachexia, showed it smaller than usual in four cases, with one of normal size.

Virchow has called attention to the analogy between the tissue of the thyroid gland, the envelope of the supra-renal capsule and the large lobe of the hypophysis cerebri. He calls any inflammation of these tissues a struma. Schiff was unable to find any vicarious action in the capsules for the thyroid gland, but Rogowitsch observed changes in the hypophysis of animals after thyroidectomy. Stieda confirmed this observation and recorded the changes. But neither noticed any unusual colloid secretion. Few observations have yet been made on human beings; the English myxedema committee could not discover any change in the hypophysis in five cases investigated. Bourneville and Bricon record a case of sporadic cretinism where the thyroid gland was missing, with a hypertrophied hypophysis. Gley, Vassale and Sacchi have experimentally removed the hypophysis and believe that it was followed by the same results as thyroidectomy. Lange implanted in a dog in the course of a month eight different hypophyses, some under the skin, some in the abdomen, some in the tunica vaginalis and some in the testes. Then he performed thyroidectomy upon him. Cachexia followed in the usual way, a typical case. Dissection showed that each hypophysis had been aborted. I feel that further research is needed before any authoritative opinion can be advanced, and I warn investigators not to draw pathologic

conclusions too hastily from the size of an organ like the hypophysis. The intimate relations between the hypophysis and the thyroid gland can be traced in the development of the organism. Dohrn has demonstrated that the former is evolved out of the ectoderm and believes that it is the remains of an original gill formation in front of the mouth. The hypophysis of the petromyxon has never been removed from its original position and stands on the same plane as the thyroid gland.

Marie and Marinesco were the first to connect the thyroid glands with acromegaly. Souza-Leithe's work on acromegaly announced that atrophy of the glands is far more frequent an accompaniment than hypertrophy, and that the marked increase in the size of the hypophysis is the only inevitable pathologic anatomic indication in acromegaly, which he considers a pituitary cachexia. We are still in doubt as to the functions of the thymus gland, although Marie asserts that in congenital myxedema the thymus is hypertrophied and does not decrease in size. It is also hypertrophied in myxedema after maturity. This persistence of the thymus gland is also noticed in acromegaly and not infrequently in exophthalmic goitre.

The different phenomena in thyroid cachexia in human beings and in animals whose thyroid glands have been removed, all tend to confirm the above theories and suppositions in regard to the functions of the thyroid glands.

All experiments and observations show that this cachexia is toxic. The nervous disturbances accompanying it are either increased action resembling tetanus in its effects or paralysis, producing the opposite effects. The seat of all this nervous trouble is in the medulla oblongata, according to Lanz's investigations, but the tetanic convulsions are controlled by higher centers, we know. Death is produced by a bulbar paralysis of the respiratory organs. Other nervous complications are disturbances in the circulation, respiration, digestion, growth and urogenital functions, accompanied by the special symptoms of decreased pressure of the blood, decrease in the number and power of resistance of the erythrocytes, with leucocytosis, diminished amount of O. in the arterial blood, increased rapidity of respiration, glycuria, depressed sexual function, menstrual disturbances, vomiting, stunted growth and difficulty in swallowing. The chemie theory of animal therapeutics is this, that all these symptoms can be cured by introducing into the organism in some way the substance of which the thyroid gland is composed.

The epoch-making discovery that death could be prevented in animals whose thyroid glands had been removed and the animals restored to health, by implanting sound thyroid glands with subcutaneous injections of thyroid gland extract, was confirmed by the individual researches of Horsley, Eiselsberg, Gley, Vassale, Tizzoni, Centanni and Mouru. In 1889 and 1890 Bircher and Horsley applied this discovery in their practice and implanted a sound thyroid gland in the abdomen in severe cases of cachexia thyreopriva. Horsley preferred to use glands from apes or sheep for intraperitoneal or subcutaneous implantation. Sixteen cases are now on record treated with part human, part animal thyroid glands, some of them with very favorable results, others with only temporary improvement. Only in the cases of Collins and Macpherson was the improvement observed as long as a year and a half. Wölfler's "Surgical Treatment of Goitre" recommends the immediate insertion of a thyroid gland from a lamb, dog or cat in the neck or peritoneum whenever struma maligna has made necessary the removal of a goitrous growth. Even where the effect is only temporary it perhaps may stimulate the accessory glands, the hypophysis cerebri, etc., to an extra compensating function.

It is to a pupil of Horsley's, Murray, that we owe the next advance from these primitive to more scientific methods. Murray prepared for injection a carbolyzed glycerin extract of thyroid glands from animals, which was used in myxedema and cretinism and quite supplanted implantation of the glands.

Bouchard inaugurated a similar improvement in France. MacKenzie in 1892 tried to produce the same results by feeding raw thyroid glands to his patients, which was also attempted by Howitz in Denmark. Since then the dead thyroid gland is administered "per os" almost exclusively. A London druggist, White, prepares a pulverized extract; Vermehren, of Copenhagen, makes a pulverized glycerin extract which he calls thyroidinum, dose 0.01 to 0.03 gram pill.

Merck also prepares a thyroidinum siccatum, of which 0.6 grams equal one thyroid gland (sheep). It is prescribed as follows: Thy. sicc. 2.0. Terr. sil. et mucil. tragacanth. q. s. f. pilulæ No. xx. One to six pills a day. Or else: Thy. sicc. 2.0. Sacchar. lact. 18.0. M. f. trochisci No. 20. Sig. One to six pastilles a day. Nielsen recommends pilulæ gld. thy. siccatae. Leichtenstern orders a glycerin extract. But for reliability of action the Merck preparation is surpassed by Burroughs and Wellcome's tabloids of compressed dry thyroid gland. One tabloid equals one gland (sheep). Usual dose one-half to four tabloids a day, although I have myself administered five and six.

Experiments with these medicines on normal animals show very few results. Woodhead claims that they produce heart disease in rabbits. Hoffmann observed that healthy animals lost flesh rapidly as an effect of copious dosing with them. Vermehren's experiments with healthy persons resulted only in increased diuresis in the young, accompanied by loss of flesh in older persons, with no subjective disturbances or symptoms of any kind.

Many physicians have tested the remedies on themselves. Wendelstadt took several pastilles a day for several weeks with no result except a loss of eight kilograms in weight. Fenwick and Nielsen experimented with negative results, but Beadles, Johnston and Maude reported headaches, more rapid pulsations of the heart and insomnia following subcutaneous injections.

Experiments made quite recently by Bleibtreu and Wendelstadt show that there is a marked decrease in the albumin of the body under the influence of the thyroid gland substance, which a compensating diet failed to restore. Scholz records what had been already noticed in my clinic, that doses which, in healthy persons and in those suffering from exophthalmic goitre, increase the P_2O_5 in the excretions, do not affect the albumin.

The effect of the remedies in disease is largely individual. The younger the patient the more rapid and thorough the results. But even with advanced years the results are favorable. The susceptibility varies very much in different cases. Symptoms occur resembling those of exophthalmic goitre after very large doses (ninety-two grams raw gland in eleven days)! One questionable case is reported of myxedema where death ensued after eating part of a single sheep's gland. In the majority of cases the administration of thyroid glands is followed by a "reaction," which is called "thyroidism" when it assumes formidable proportions. This reaction appears after the first doses, especially in cases of myxedema. It begins by a slight rise of temperature and increased pulse. Too large doses are followed by fainting and collapse. All the phenomena observed in this animal therapeutics pivot, of course, on the stimulus to the central nervous system and the increased processes of change in certain substances in the organism. The increased diuresis is probably due to the action of the heart. The supply of nitrogen is increased, sometimes resulting in albuminuria or glycosuria. In a few cases especially unpleasant effects were noted, epileptic, stenocardiac and uremic attacks, tonic cramps in the extremities, stupor, loss of consciousness, and eruptions, exanthema, urticaria, erythema, etc. A squamous dermatitis often follows a cure of myxedema. These latter phenomena are the foundation for the application of these remedies to skin disorders, and the rapid loss of flesh has indicated thyroidin as a cure for obesity.

The different diseases to which this treatment has been applied are as follows: Congenital and spontaneous myxedema; cachexia and tetania thyreopriva; tetania; struma; parenchymatosa; acromegaly; exophthalmic goitre; general obesity; skin diseases—psoriasis, lupus, eczema; syphilis, leprosy, tuberculosis, cancer; mental disorders, epilepsy.

In myxedema more than 150 cases observed testify that the success of the thyroid preparations is almost absolutely certain in the spontaneous, operative and infantile forms of the disease. The few failures are not to be considered in the presence of such a number of cases cured or vastly improved, any more than the unpleasant but rarely serious attending complications in a few others. The first enthusiasm over this "therapeutic miracle" is still justified in these cases. Only the permanency of the cure is still open to discussion. The psychic complications of myxedema (amentia, stupor, acute melancholy, and mania) are also cured as the cause is removed, as is repeatedly observed in actual practice. There has not been sufficient material accumulated to decide authoritatively in regard to the efficacy of this organ therapy in tetanus. In my own practice I could not detect any appreciable results after its use, although theoretically there ought to have been.

The many points of resemblance between myxedema and exophthalmic goitre led to great expectations in the treatment of the latter with the thyroid extract, but results have not confirmed them. Some cases were made worse by its use others were cured, but only in young persons. I observed personally one cure accomplished by feeding sheep's glands, but the disease was in an early stage. Another similarly treated grew worse until treatment was abandoned. Personally, I have ceased to hope for much in this disease from this treatment.

The casual resemblance between myxedema and acromegaly stimulated many to experiment with the latter in the same way, and in a few cases a certain amount of success was obtained.

But it was in struma that the advocates of animal therapeutics hoped to score their most valuable success. Of course cystic, fibrous and malignant struma are too far advanced to derive any benefit from this treatment but simple parenchymatous struma in young persons yields to it rapidly, and permanent cures ensue in case after case. Bruns reports nine out of twelve cases cured and all improved. Four children (4-12) were entirely cured in four weeks. He used large doses but did not notice any decrease in weight except in one case. He administered fresh raw glands from calves and sheep. Reinhold fed raw sheep glands to cases where mental disorders accompanied the struma, and in five cases out of six the struma disappeared quite rapidly and completely. No inconveniences were noticed. Ewald reports eight cases of struma treated with thyroid tablets, in all of which the abnormal size of neck was decreased. Leichtenstern reports one case treated with tablets that showed no improvement. Mieulicz uses the thymus gland. With the exception of the goitre, all the symptoms in a case of Basedow's disease were benefited by eating thymus glands.

I hope that every practitioner will assume the responsibility of assisting in the accumulation of knowledge in regard to the effect of this thyroid treatment on struma. In all the cases reported so far, we find it is the diffuse hyperplasia in the young which responds best to it.

The results of this treatment in mental disorders have been very meager. Macphail, Bruce and Wagner have used it, and a few epileptics have been successfully treated with it. But I consider this application of it as well as the use of it in cutaneous troubles, foreign to its physiologic foundations, and destined eventually to bring discredit upon it, although Menzies reports certain favorable results attained in malignant syphilis.

Tuberculosis also is outside the pale of favorable results from this animal therapeutics, as Bramwell has shown and my own

experiments have confirmed. It has no influence whatever on the local processes in the lungs.

But in the treatment of general obesity, it seems to have a promising future, as has quite recently been demonstrated by York Davies, Leichtenstern and Wendelstadt.

Twenty-four successful cases out of twenty-seven is a percentage that establishes this treatment as an efficient cure for obesity. As it tends to weaken the patient, no change is made in the diet or mode of life, so that the general health is undisturbed. The greater the amount of flesh the more rapidly it vanishes with this treatment. The diuresis was increased at first. The anemic obese seemed specially benefited. Leichtenstern's successes in this line are very important. If the results are permanent and the treatment without perilous after-consequences, we will certainly have in animal therapeutics a specific against undue obesity.

But my own observations and experiences lead me to call attention to its limitations, as it is only in certain kinds of obesity that it is beneficial. Robust, red-lipped young people, with strong muscles and a good appetite, did not lose more than two to five k. in their weight, and I noticed symptoms of palpitation of the heart after treatment. Anemic obesity is the kind benefited, and in all cases the action of the heart must be watched.

I have taken pains to place before you the details of the medicatio thyreoida as a shining example of what can be accomplished by concerted effort, in experimental research and the clinic. It is in fact, a brilliant, almost marvelous achievement which may be a stepping-stone to future successes of vital importance.

The pancreas has also been used in treatment like the thyroid gland, but with little or no success, although such men as Minkowski, Hedon and Gley have tried it in every form. Several times I have used it in my own practice, and should try it again in cases of diabetes that indicated pancreatic disturbance. The best method of administering it is "per os."

Experiments with the supra-renal capsule show that its removal in animals is followed by emaciation, feebleness and death, and that injections of fresh extract of the organ retard death at least. Abelous, Langlois, Pfaunder and Holl have been especially active in these researches. The latter announce that the capsules secrete a substance in the form of very fine granules, which find their way into the blood, but not through the lymph passages of the gland; a discovery that ranks in importance beside Hürthle's in regard to the secretions of the thyroid glands. No practical results have been secured yet: a few cases of Addison's disease have been treated, but with no success except an increased diuresis.

The much-criticised medicatio orchitica was inaugurated by an interesting experiment by its author, Brown-Séquard, on his own person. By injections of the secretions of the testes he believed that he had regained all the energy of earlier years. He was able to resume his work in the laboratory, and the dynamometer registered increased motor power. Diuresis increased and the torpid condition of the bowels gave way to normal processes. Experiments on other persons resulted also in increased cerebral action and revived sexual impulses. Brown-Séquard drew the conclusion from these facts that the secretions of the testes exerted a specific dynamogenic force on the nervous system. He concluded, also, from these premises, that early castration in men and animals produced profound disturbances in the nutrition and growth, and that sexual excesses must play an important role as one of the causes of various nervous diseases.

The best preparation of Brown-Séquard's testes extract is that made by W. Vogt in Geneva. It is for subcutaneous use, in doses of from 2 to 8 grams a day. The indications for its use are conditions of weakness, senile or resulting from malaria, hemorrhages, leprosy or tuberculosis, and nervous troubles,

especially tabes dorsalis, neurasthenia, epilepsy, chorea, paralysis agitans and psychic disorders.

Fürbringer, Senator, Ewald, and some others, consider this orchitic remedy utterly valueless, and the only effects produced due to auto-suggestion alone. In my own experience, I have never known it to succeed in cases of impotency, but I have witnessed surprising improvement in muscular energy in several cases of neurasthenia. Pregl, of the Rollet Institute, is soon to publish an account of his observations on this subject, which will probably add much to our knowledge of it.

Babes and Paul have made a glycerin brain extract, which seems to be only an offshoot of the orchitic remedy idea. It has scarcely been tested as yet.

The spinal cord seems to possess a certain curative power in anemia, but it is not yet time to express any opinion in regard to it. In conclusion, I will say that animal therapeutics constitutes an advance in therapeutics which every practitioner must appreciate. But I do not disguise the fact that it includes a certain danger for our science.

It seems a serious matter to me to consider these therapeutic methods as such *in genere*, and the attempt to substitute directly a sound for a diseased organ is certainly an absurd undertaking. An industry, not any too careful, has already assumed control of this animal therapeutics, and a crowd of indiscriminating writers will probably continue to announce signs and wonders that throws the old women's remedies, "virgin's urine," etc., into the shade. The only way to separate the wheat from the chaff is not by way of the laboratory alone. Physiologic chemistry and experimental physiology may separate the secretions of the organs into their components and determine their toxic processes, but, after all, it is the practicing physician who applies the facts they discover. He must be neither too skeptical nor too confiding, but remember what Dedalus said when he entrusted his wings to his son: "In medio tutissimus ibis." Translated from the *Therapeutische Wochenschrift* of Jan. 26, 1896.

Technical Terms in Electricity; Their Simplicity and Practical Importance. We are confronted by the manifestations of electricity on every hand nowadays, and the modern physician should be posted not only in regard to his own little therapeutic electric machines, but also in regard to the applications of electricity on a large scale, in order to prevent accidents, and manage them after they occur. The technical terms used in electricity are beautifully simple and practical, while they commemorate the names of men whose contributions to science and industry are inestimable. For the sake of convenience, we speak of the electric current as a fluid, which it is not. We must remember that this is a figurative language. The fact is, that nothing actually flows from one pole to the other, but that the intervening substance has imparted to it by the electrification some "mode of motion," some condition of matter, some "vibration or tension of the molecules of the body said to be electrified." But it resembles a fluid in many respects; for instance, the way in which the electricity always rushes from the higher potential to the lower, through the intervening wires or substances, as water always seeks the lower level. The measure of the force which the electricity exerts in this, is called a volt. The measure of the resistance offered by the conductors to this electromotive force, similar to the resistance and friction offered by the pipes to flowing water, is called an ohm. As the electric force triumphs over the resistance, the amount of electricity that passes on over the circuit, divided by the time, produces the measure of the intensity of the current, the ampère. The unit of electrical power is the product of the pressure (electromotive force) of a current in volts, when multiplied by the volume expressed in ampères. The watt is the term used to express this volt ampère unit of electrical energy. It equals 1.746 horsepower. The watt is the force of a current one ampère at a tension of one volt, and this term shows best the admirable simplicity of this technical language. If you wish to light your residence with twelve lamps of fifteen candle power each, when you are told that each candle power represents 3.5 watts, you know at once that you require 15×3.5

watts, which is 52.5 watts, and for twelve lamps, 630 watts. The other terms used are the farad, the unity of capacity; and the coulomb, the working unit of electricity. This represents a current having the strength of one ampère, passing through a one-ohm resistance conductor in one second of time. With these terms we all ought to be familiar, and not send back for the volts, when an invoice of "fifty lamps of twenty candle-power and forty-five volts" is delivered at your house, as the story is told of some one. —*Journal des Sciences Méd. de Lille*, January 4.

Filaria of the Eye. According to the *Annales d'Oculistique*, Dr. Hirschberg has recently exhibited before the Berlin Medical Society a specimen of filaria which was extracted from the eye of a negro. It was situated between the conjunctiva and the sclera. It was recognized as a female worm by its rounded head and pointed tail. In the last century a French physician, Vigo, while traveling in the province of Angola, noticed that this worm was frequently present in the eyes of negroes. Vigo performed five operations for its removal, two of which were successful. He introduced a curved needle between the worm and the sclera and pressed on the worm with this needle so as to force it out through the conjunctiva. During the present century, a physician of the French navy removed a similar parasite from the eye of a Congo negro. Another physician at the Gaboon observed analogous cases and claims to have found that the worm could emigrate from one eye to the other by a subcutaneous route around the root of the nose. He stated that the patient could feel the passage of the parasite, and that there was intense pain when the worm approached the cornea, into which, however, it never penetrated. This parasite was also observed in America and in the Antilles at the time when slaves were imported. Europeans who reside, or who have resided, in countries where this parasite exists may also be bearers of it. A Scotch woman, thirty-two years of age, who had lived at the Mission Station of Old Calabar, in the northwest of the Cameroons, found, on her return to Europe, that she had a worm in her eye. It was extracted by Dr. Argyll Robertson. The mechanism of the introduction of the worm into the eye is not understood. It has been suggested the mosquito is the host in which the larvæ of this parasite are developed. After being thus developed in the insect they are then introduced into water. The worm exists in endemic condition from Angola to the Gaboon, from the fifth degree of north latitude to the tenth degree of south latitude on the west coast of Africa.

Chronic Cancer of the Breast of more than Thirty Years' Duration.—Munn (*British Medical Journal*, Feb. 22, 1896) read a paper before the Clinical Society of London concerning chronic cancer of the breast, which formed a continuation of two former papers read before this Society in 1872 and 1878 and recorded in Vols. vi and vii of the Transactions. The patient first came under observation in 1862, being then 37 years old, and mother of one child. Menstruation had ceased at 30. There was then a scirrhus tumor of the breast and a chain of enlarged glands in the axilla. The breast was removed by Mr. Munn in September, 1862. Four years later pain was complained of in the muscles of the arms and the fingers; this pain soon passed away. In 1868 the patient was no worse. In 1878 a limited recurrence took place in the upper angle of the scar. In 1893, more than 30 years from the commencement of the tumor there was an increase in the cancer deposits, and the arm was swollen. In October, 1895, Munn found the patient still living and energetic, and doing work as a charwoman. The patient in Case 2 (1878) died a year after Munn's report of the case. The autopsy revealed secondary tumors in the lungs and in the liver. The exact duration of the disease in this case is not mentioned in Mr. Munn's last paper. Drawings were presented showing the carcinomatous structure. As a further illustration of chronic cancer mention was made of a case of which microscopic sections of the recurrent tumor removed by Mr. Munn were presented to London Pathological Society in 1880, the original tumor having been removed seven years previously by Mr. Curling. A second recurrence was operated upon by Mr. Lawson in 1882, and the patient was, until lately, still living. In the discussion Mr. Marsh recalled the case of a woman, now 71 years of age, who has had a carcinoma of the breast almost continuously for eighteen years. A few weeks ago he has made the tenth operation which she had undergone. These cases show that patients in whom recurrence does not take place within three years can not always be regarded as cured.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, MARCH 14, 1896.

THE ATLANTA MEETING.

The universal recognition of scientific progress and revolution can not be avoided. The man who doubts this must be very blind and very deaf and very feeble mentally.

In all the large cities the progress in electricity forces itself into observation, and an intense expectancy pervades everywhere. The field of medicine is no exception. The Baltimore meeting appeared like many others which had gone before. Members who listened to the various papers read failed largely to recognize their true significance. Only after, when these papers appeared in the JOURNAL from week to week, did the fact dawn that medicine was advancing. This Baltimore meeting, more than all others, exhibited a restless onward movement of medicine outside of conventional lines and boundaries of the past. This was not so much apparent in the novelties and innovations proposed as in the doubt and questioning, and demand for evidence for the present theories.

The pages of the JOURNAL show that a new era has dawned for American medicine, and the AMERICAN MEDICAL ASSOCIATION gives voice and expression to this more clearly than ever before.

Local and State societies, and societies of specialists, all have a power and place in this movement, but the National society, of all others, must concentrate, mobilize and direct this progress. The coming meeting will show a great advance in many ways and higher ground will be occupied along many lines of science. The application in medicine of the new photography from the Roentgen rays will be presented with some new results. New discoveries of brain anatomy, and new facts along many practical lines of work, are already promised. The scientific outlook for the

coming meeting is of unusual interest. National medicine has passed beyond any personal local influences and demands the best facts from every source. The village and country doctor is welcomed for any facts he may bring. Distinctions of place and position all become insignificant compared with truth and new facts, and new evidence from any source.

The many sectional meetings give every man a chance to compare his experience and opinions with others from all parts of the country.

Critical physicians may stand aloof and sneer down the ASSOCIATION as a medical ring, and mob convention, but the fact can not be ignored that it is the most influential gathering on this continent. The JOURNAL and its contents are the unmistakable evidence of this fact. Not far away this will be recognized and the ASSOCIATION meetings will have thousands in attendance where it has only hundreds now.

The Atlanta meeting will bring out a large number of active men in the new South land who will be leaders in the years to come. All members from the West and North should embrace this opportunity to create a new scientific interest, and enlist a new class of men, who will bring new facts and new experiences to our work. It should be a duty and source of pride to every member of our ASSOCIATION to attend its annual meetings and prove to their home circle of friends that they are not merely medical hewers of wood and mechanical nurses, but scientific men interested in the great movements for the welfare of humanity.

More than this every member who attends the ASSOCIATION meetings secures a certain character and position, not only to himself personally, but to those he comes in contact with. This can not be bought with money or power; it only comes from association and interest in medicine with others at these great National gatherings.

Let every one show his interest in science, in humanity, and in the struggle against disease and death, and come to Atlanta, and he will go back stronger and better fitted for his work.

THE SIGNIFICANCE OF GRADE, RANK AND TITLE
IN THEIR NAVAL MEDICAL RELATIONS.

The development of the new Navy is a matter of popular concern and the expensive outlay it involves is acquiesced in by the most exacting appropriation watchers. That the *personnel*, barely sufficient for a few old time wooden vessels, needs to be similarly expanded in men and officers apace with modern battle-ships, cruisers and coast-defenders is not questioned, but Washington correspondents declare that Congress finds such difficulty in reconciling the opposing factions of the Navy that in all probability the session will close without any legislation in this direction. It may be profitable for us as physicians to inquire in

what manner the interests of our naval medical confrères are affected by this internecine conflict, and who is responsible for obstructing the reorganization which is admittedly necessary.

It is well known that the officers of the Navy have been for many years divided into two bitterly hostile parties—one comprehensively termed the *line*, charged with the executive, navigating and artillerist duties—the other collectively, the *staff*, comprising the medical, pay, engineer, construction and certain minor corps. The same divisions of line and staff exist in the Army but without factional friction and enmity, and the civilian, the citizen soldier and the regular army officer are equally unable to understand why this antagonism should prevail in the navy which is unknown in the army—why it should exist in the navy of the United States and not in that of other nations. The naval medical officer is as accomplished, as competent, as well appearing and as well descended as his army colleague; why then should a naval line officer seek to assert a military superiority over his medical associate which never occurs to the army line officer to exhibit toward the medical officers of his own military family? The embryo naval cadets come from the same sources as the military cadets; they represent every class of society; some of them are of very humble antecedents, but a single term at the Naval Academy often makes the son of the laborer as the son of the millionaire an arrogant and offensively supercilious pretender to inherent superiority (though his own father and brother may be staff officers), which neither his duties nor requirements justify.

The status of the army officer is as well understood outside the army as within its ranks, through the wide distribution of the volunteer forces and national guard. Every one knows how they are graded; everyone knows what is a colonel though he be of the engineers or artillery, a major though of the medical corps or cavalry, a captain though of the infantry or pay corps—the special arm or corps being indicated when officially necessary by distinctive titles and uniform, and on occasions of merely social intercourse being never considered. This is so simple and rational that it is puzzling to understand why there should be any difficulty about it in the navy. The commissioned officers of the navy are arranged by law in certain *grades*: rear admiral, commodore, captain, commander, lieutenant-commander, lieutenant, lieutenant of the junior grade, and ensign, which are commonly but erroneously spoken of as *ranks*, the terms *grade*, *rank* and *title* being confounded and assumed to be synonymous and appropriated by the line as their generic distinctions, whence their claim that they alone constitute the navy, while all other officers, whose commissions are phrased in identical terms with their own, except as to *title*, are, they assert, only accessory but not essential, and this fallacy is the single *casus belli*

in the service, as a clear understanding of the significance of terms will make evident.

Grade is that something, the law has conferred upon *all commissioned officers*, which serves to show the officer's place, position or status in a military organization. *Rank* means simply seniority or precedence in the several grades and depends upon the date of the officer's commission; thus, one officer ranks another in his own grade. While custom has sanctioned using grade and rank as synonymous, this is not correct, since the word rank is not employed in the statutes to give any officer his official place or position in the naval organization any more than in the military. Grades in the military organizations of all civilized nations are practically the same, corresponding names being given these grades in the several languages, and to show the correspondence of naval grades with these military grades, the law defines that a rear admiral shall have the relative rank of major general, commodore that of brigade general, captain that of colonel, etc., the expression *relative rank* not implying any other relation than that of absolute equivalence. Unfortunately, the same term *relative rank* has been used in defining the correspondence of the grades into which the staff corps have been divided with those of the line, for while the intent of the law is precisely the same in the one case as in the other, sea-lawyers have quibbled to make it appear that relative rank as applied to staff officers is not real, though the same reasoning would invalidate their own precedence with the army. In the case of the medical corps the grades are medical director, medical inspector, surgeon, passed assistant surgeon and assistant surgeon—these being in fact only *titles* and not *grades*; since a medical director may have the relative rank of commodore or captain, a surgeon that of lieutenant-commander or lieutenant, and a passed assistant surgeon that of lieutenant or lieutenant of the junior grade; while in the engineer corps the confusion is still greater, for the *title* chief engineer is bestowed upon five separate grades of officers. The sole cause of the lamentable dissensions in the navy is the assumption by the line of a vested right to be considered the navy, all other officers not being officers at all, because they are not specifically stated to be of the same grades as themselves and they oppose legislation to this effect, affecting to believe that it would lead to conflict of authority, herein making the mistake that authority is inherent in any grade, and in face of the army precedent where no such conflict occurs. It is unnecessary to declare that no medical officer in the navy aspires to be confounded with any line officer, nor does he wish to exercise his functions, nor desire anything but to have the actual grade to which his commission entitles him established as has been done in the army, coupling with it the corps to which he belongs, and if

necessary a distinctive medical title to indicate his specific duty.

The significance of the terms grade, rank and title are, it is hoped made apparent. There is no reason why, as in the army where Colonel—, Fourth Artillery, Major —, Engineer Corps, and Captain —, Medical Corps U. S. Army, sufficiently indicate the individual and his office, Captain — of the Line, Commander — of the Medical Corps and Lieutenant — of the Engineer Corps, U. S. Navy, should not be equally distinctive. The precedent already exists in the Navy, where Captain — of the Marine Corps fills his comparatively junior grade, despite his title without in any way detracting from the greater glory of Captain —, who may command the vessel on which both are serving. As already stated, the misunderstanding in the navy arises from the false premise that the titular grades of the line indicate inherent duties instead of being merely gradation terms. The word captain denotes nothing more than the third grade of commissioned officers in the navy, as it does the sixth in the army and marine corps, and not an individual, who of necessity commands a first rate man-of-war. When such duty is assigned to him, his distinctive title becomes "captain commanding," which sufficiently indicates his specific duty. There are to-day on board the flagship *New York*, three men who are officially designated as captain, the captain commanding the ship, the commander who is chief of staff and the captain commanding the marine guard. Nothing has been heard of a conflict of authority between these men by reason of all possessing the same title, although they belong to three different grades, the word captain in the case of the marine officer, as in the army, being three grades below that of captain in the line. Why should there be any conflict if the medical officer or engineer were so designated in their respective corps? Congress has therefore only to declare that all commissioned officers of the navy shall be divided into certain grades, as in the army, the corps to which each officer belongs being appended, and no more will be heard of line and staff contentions. Indeed the only dissension will be that which has recently developed between the young officers of the line, who wish to turn out the old ones, and these old line officers, who do not wish to be turned out, arguing most plausibly that the man who has seen thirty years faithful, efficient, honorable service has far more claim upon his country than the youth, who has served but three.

ACUTE LEUKEMIA.

Leukemia and other forms of essentially chronic blood disease are of more than ordinary interest because of their as yet unknown etiology. It would seem that not until their genesis is fully made clear can there be any reasonable chance for securing effi-

cient therapeutic measures. Any observations that throw some new light upon such obscure diseases as leukemia are consequently of great value from a practical as well as from a theoretical point of view. Leukemia occasionally appears in the form of an acute disease. This manifestation might, if thoroughly studied, furnish some reliable indications as to the direction in which the solution of the etiologic problem referred to should be sought.

A. FRAENKEL¹ has recently published a series of articles upon the acute form of leukemia. He deals with the observations relative to six male and four female patients. The duration of the disease varied from twenty days to sixteen weeks. In four patients the age was between 13 and 18 years, in six between 24 and 34. Characteristic in all the cases was the sudden onset and the early appearance of symptoms such as multiple hemorrhages, which in chronic leukemia are observed only in the latter periods of the disease. In eight cases, in which the blood was carefully examined, the findings were uniform but of a somewhat different nature, in some respects, than in chronic leukemia. In addition to the falling off in the red corpuscles and the increase in the white, it was found that the excess of white cells depended exclusively upon the presence of an increased number of mono-nuclear elements, or lymphocytes. These lymphocytes were of varying size. They showed transition forms, however, that pointed to their all belonging to the same developmental series. The larger were the most numerous and showed a large nucleus, poor in chromatin, that almost filled the whole protoplasmic cell body. The nuclei occasionally presented divisions into two. Eosinophile or neutrophile cells were not present. Basophile cells were found occasionally. The number of polynuclear leucocytes was very small. In three cases mitotic figures were present in the blood in the capillaries of various internal organs. Nucleated red corpuscles were found in small numbers; only in two cases were such cells rather numerous. On the warm stage these lymphocytes failed to exhibit any amoeboid movement.

Smear preparations from the spleen, the bonemarrow and the lymphatic glands showed that the mono-nuclear white cells were most numerous in the swollen lymphatic glands; sections from the lymphatic glands showed appearances favoring this conclusion. There was consequently a lymphemia, the youthful forms of leucocytes predominating; hence the proliferation of white cells must be very active and their passing from the seat of formation into the circulation must ensue rapidly. This corresponds to the acuteness of the clinical picture. In chronic leukemia this passage into the circulation takes longer time and the lymphocytes have a chance to undergo transformation into

¹ Deutsche med. Wochenschrift, 1895, Nos. 39 to 43, and No. 45.

cells with granulations in their interior and to form polynuclear elements. The latter forms are actually and relatively diminished in number in acute leukemia: the conditions necessary for the transformation of their early stages of development—the youthful lymphocytes—are not present or have been disturbed.

In all probability the etiologic factors are identical in the acute as well as in the chronic forms of leukemia. Transition forms between the acute and the chronic varieties have been described by reliable observers.

The course of acute leukemia points to its being an infectious disease. In two of FRAENKEL'S cases the complete absence of bacteria in the blood was fully demonstrated. The question as to an auto-intoxication from the gastro-intestinal tract is an open one. The early and constant swelling of the cervical lymphatic glands points to the possibility that the virus may enter from the mouth or from the pharyngeal cavity.

Two of FRAENKEL'S cases are noteworthy on account of the manner of their termination, namely, a rapid and constant subsidence of all leukemic manifestations up to the very moment of death. This occurred under the influence of an intercurrent bacterial infection, a septicemia due to staphylococci, and colon bacilli respectively. Disintegration of the leucocytes in the blood and in their seats of formation occurred in these two cases as shown by the appearance of the blood and of the glands, and this was accompanied with a rapid exacerbation of the general condition which led to the belief that a ferment intoxication was taking place; in one of these cases there was also a marked increase in the excretion of uric acid. The disintegration of the white cells must consequently be of essential influence upon the amount of uric acid excretion.

These latter phenomena that occurred apparently as a direct consequence of the bacterial infection leads FRAENKEL to direct attention to the possibility of a rational therapy: The treatment of leukemia with bacterial products or with other substances that exercise a formative stimulus upon the blood-forming organs and favor the normal transformation of the young leucocytic cell forms into polynuclear leucocytes.

MORAL INSANITY.

Recently a very reputable medical man was convicted of a heinous crime and sentenced to prison for life. In the effort to collect facts to be used in securing pardon, the counsel discovered a most unusual life of hypocrisy. He had been cruel and harsh from boyhood. He enjoyed causing pain and suffering in others, and as a student he fairly reveled in the agony of animals in vivisections, and the pain of persons diseased. To this was added great egotism and love

of personal praise. He ruined his father's property in apparent speculation. He was a bitter enemy to his brothers and sisters, and was indirectly the cause of the death of his wife, and drove his children from home. He was not miserly but was, in his inner life, thoroughly dishonest, and without the slightest conception of honor or duty to others. Yet he kept up a fair exterior, was a teacher in a medical college, with a large practice, and had no popular vices such as drinking or gambling. The more his history was studied the worse it appeared. Deception, fraud and dishonesty marked every stage, and yet it was largely purposeless and without reasonable motive.

The facts taken together had only one conclusion and that was moral insanity. Some condition of the brain was literally deranged and malformed. Some central part that had not developed had been steadily retrograding. However difficult it may be to explain and make clear this term, there are classes of facts that can be described by no other name.

The common expressions, vice, wickedness and depravity, used in the moral sense, become more and more confusing with each advance of science, and their use in any technical way is unfortunate for accuracy. The higher governing centers of the brain are clearly distinct from the lower, and what is moral, meaning the consciousness of duty and obligation to others, and conceptions of right and wrong, is clearly a later development. Evidently these centers are governed by the same laws which work in harmony in the healthy person, but may diverge greatly in other conditions. The belief that these centers may be undeveloped and diseased is along the line and sustained by both the physiologic and psychologic laws of existence and growth.

The legal fear that the recognition of this disorder will be an excuse for crime is purely theoretical and visionary.

The greatest danger comes from the want of recognition of the actual physical states which are manifest in criminal immoral conduct, conduct that may not come under legal recognition, but is nevertheless disease and wide departure from the normal standard.

Every physician comes in contact with persons who show by their acts insanity of every element that enters into the higher mentality. The terms commonly used to describe this condition should pass out of all accurate language.

Medical men should study the facts of these cases, confident that they will all be found to come under some general law of disease and degeneration.

Had the actual physical condition of this doctor been known, the disaster of his life and the suffering of others might have been averted. Arguments over definitions and terms are absurd, the reality of moral insanity can be proven from facts which have no other meaning.

THE MEDICAL EXAMINERS' BILL IN THE NEW YORK STATE LEGISLATURE.

Another and very serious attempt is being made in the New York Legislature to secure the abolition of the office of coroner, by a bill that will create a system of medical examination that will in large measure be divorced from politics. The medical examiners will be bona fide medico-legal officers, since they are to be appointed by the Appellate Divisions of the Supreme Court in each of the four Appellate Districts of the State. The number of examiners has not yet been settled definitely.

The medical examiners must be physicians of good standing, fulfilling the requirements which the Appellate Divisions of the Supreme Court are authorized to establish. They are required to give bonds for the proper performance of their duties, and are removable by the appointing power. Several of the Appellate Judges have been consulted about the placing of the appointing power in that branch of the State government, and they are in favor of it, for the reason, chiefly, that the new officers will be as far as possible removed from political influences. Their salaries will be fixed by the Court in proportion to the amount of work required of them in their several districts. Their term of office will be six years.

The medical examiners and assistant medical examiners shall be duly licensed and registered physicians, and their appointment shall be made according to merit and fitness, to be ascertained, so far as practicable, by such examinations as the Appellate Divisions for each department shall prescribe.

In case of the death, resignation or removal of any medical examiner, or assistant medical examiner, in the district of the Appellate Judges who appointed him, the same division may appoint his successor for the full term of six years. Any medical examiner, or assistant medical examiner, may be removed at any time for cause shown by the Appellate Division of the judicial department which appointed him.

Each medical examiner and each assistant medical examiner shall give bonds for \$5,000, conditioned on the faithful performance of their duties.

Coroners' juries are abolished, because they are only training schools for witnesses, and because their findings have no force whatever.

CORRESPONDENCE.

A Permanent Badge for the American Medical Association.

DETROIT, MICH., March 6, 1896.

To the Editor:—I have been very much interested in the discussion on the subject of insignia of the medical department U. S. A. Now that the board of officers, of which Col. Chas. H. Alden, Assistant Surgeon General U. S. A., is president, has concluded its labors and rendered its report and recommendation to the Surgeon General, it may not be amiss to con-

sider the subject of a permanent badge for the AMERICAN MEDICAL ASSOCIATION.

At each annual meeting of the ASSOCIATION we are presented with a new badge. At San Francisco the badge consisted of an escutcheon bearing the arms of California, etc. The escutcheon, which was made of silver, was suspended from a pin made in the semblance of a bear, composed of some kind of metal coated with gold. It was a beautiful badge, and cost the local medical societies and those who contributed to it quite a large sum of money. Sometimes we are decorated with a badge that would do credit to a firemen's parade. Now, if we had a permanent badge that could be worn by members of the ASSOCIATION at all times, it would serve as a method of recognition at the annual meetings, or whenever two members of the ASSOCIATION should meet by chance.

The best form of badge would probably be a button worn in the lapel. At the annual meetings a ribbon could be suspended from it, bearing the name of the State represented by the delegate.

I have considered a number of designs for such a badge, among them, the red cross of the Geneva Convention on a white field and surrounded by a narrow band of blue. This would be an appropriate design, red, white and blue. By referring to the paper of Col. R. French Stone, Surgeon General Indiana National Guard, entitled "Proposed International Medical Insignia," which was published in the JOURNAL, February 29, the outline of design referred to will be seen on page 405; Col. Stone suggested this emblem for use not only by the army but by the doctors in civil life throughout the world. He recommended a dark green field with a modified form of the red Maltese cross surrounded by a narrow strip of gold. His suggestion may be more appropriate than mine, but I do not think the contrast between the red cross and the dark green field is as marked as that between the white, red and blue which I have recommended.

The object of my communication, however, is to excite interest in the subject of a permanent badge for the AMERICAN MEDICAL ASSOCIATION, leaving the design to be considered afterward, first finding out whether a permanent badge of the ASSOCIATION is desired or not.

In conversation with several prominent members of the ASSOCIATION, at different times, I have broached the subject of a permanent badge, and the suggestion has been viewed with so much favor that I feel justified in presenting the matter more generally to the ASSOCIATION through the columns of the JOURNAL. I would be glad to receive any communication on the subject from members of the ASSOCIATION. Address communications to 106 Charlotte Avenue, Detroit, Mich.

F. E. STEWART, M.D.

The Use of Proto-Nuclein.

GOSHEN, IND., March 7, 1896.

To the Editor:—I am much obliged to you for the space you were kind enough to give my article on proto-nuclein and a case treated with that medicine alone. I am still prescribing proto-nuclein in my daily practice, with increased confidence. I am free to state I have had more satisfactory results from this medicine than from any one remedy I have ever prescribed, except, perhaps quinin in malaria. Having had quite a long experience in the practice of medicine, I trust I am not entirely deceived. Allow me briefly to note a case.

Early in the morning of October 15, last, I was called to attend a Mrs. S., aged 30, residing in this city. I learned she was taken violently sick in the night, six hours before I saw her. Had chills, very high fever, temperature 104, pain and sore throat. On examination I found the right tonsil entirely covered with a thick diphtheritic membrane. About 2 o'clock in the afternoon the exudation made its appearance on the left tonsil, extending back to the fauces and posterior nares. The

patient had a hoarse cough and smothering sensation, indicating that the disease was extending to larynx and trachea. As local treatment, using the powder blower, I covered the diseased parts with proto-nuclein special every four hours, blowing the same up the nostrils, and having patient inhale the dust as much as possible. For internal treatment, three grain doses of proto-nuclein powder were given every three hours, and continued for six days. The effect of this treatment was to check and hold the disease from the very beginning. On the second day the membrane began to loosen and thin out, and by the evening of the third day it had entirely disappeared. Two days later flakes of membrane were raised from the larynx and trachea, which had evidently formed on the first day. No other medicine, whatever, was given, except a dose of morphin at night. This patient made a delightful recovery, free from the weak and poisoned condition that follows even a mild diphtheria. And this is the *beauty* of the proto-nuclein treatment, convalescents invariably come out bright and fresh, free from defective secretions and poisoned blood.

In this locality the past season, almost every malignant diphtheria has extended to the larynx and trachea and those cases have been invariably fatal—such, no doubt, would have been the result in this case, only for the prompt arrest. I never saw a more violent attack. There were three persons exposed, mother, husband and little son. As preventive they were all given the same internal treatment, the main patient was taking. The husband had a very mild diphtheria, which required a couple of local treatments. The other two escaped entirely.

Respectfully,

A. C. JACKSON.

A New Picture Process.

DES MOINES, IOWA, March 9, 1896.

To the Editor:—I have taken considerable interest in the published reports of the penetration of Roentgen's X rays and the application of the discovery to surgery; as well as to reports of similar results without the use of Crookes tubes. By virtue of accident I can report similar result independent of Crookes tube, dynamo, or any other agent of electrical light or force, so far as I know. Some months ago I placed a piece of sensitized paper in a book and it was forgotten. When discovered a few days ago, the page of the book was clearly and legibly printed upon the sensitized paper, as a positive. The discovery was so bewildering that I did not think of fixing it at the time, but next morning, when I went to do so, the image had vanished, and I lost the evidence of what I saw. The experiment, however, can be repeated by any one. If the impression had been from ink or oil it would not have faded.

A. G. FIELD, M.D.

PUBLIC HEALTH.

Effect of Water on Diphtheria Germs. Demetria has been experimenting on the Löffler bacillus to determine whether it retains its virulence in water. (*Arch. de Méd. exp.*) He found that it rapidly loses its primitive virulence in distilled water as well as in sterilized, and also in running water, but that it promptly regains it when transplanted to a favorable soil. Fresh, running water seems most destructive to the bacilli, as they disappear in it in seven to nine days. *Revista de Ciencias Modernas*, February 5.

An Infectious Disease Hospital to be Located on Manhattan Island.—There has been introduced into the legislature a bill authorizing the mayor and aldermen of New York city to convey to the Diphtheria and Scarlet Fever Hospital a site at East Seventeenth Street and the East River. This is the hospital which is to be built and managed by Mrs. Minturn and a number of other spirited ladies of New York city. The location is isolated and there has been no objection to the bill because it would

endanger public health. There is now no hospital on Manhattan Island which will receive persons stricken with diphtheria or scarlet fever, and they must be bundled off to the Pest Hospital on Randall's Island. The proposed hospital is to fill that want, and the bill will pass.

Vulpine Rabies in Russia. The *Sanitary Record* refers to the fine paternal care displayed by the Russian government on behalf of the unfortunates who fall victims to the bite of the wolf. It says: "The following is the record of the Pasteur Institute in Paris for 1894: 1,387 patients were treated, 7 of whom died. When Pasteur made his anti-rabic discovery he was besieged by men from Russia, some of whom had been bitten by wolves. Many of them could reach Paris only when too late, and the Czar at once, on being convinced of the efficacy of the treatment, sent pupils to be trained, and established centers of cure in Russia that have obviated the necessity of the long journey, so that during the year but one patient came from Russia, while 128 came from near-by England."

New York State Board of Health.—At a meeting of this Board held February 28, Dr. Lewis, chairman, presented a report on the sanitary program for 1896 in the State. He also submitted a report on the condition of the rendering works on Barren Island. He recommended that the services of the present inspector, Arthur Hollick, be dispensed with after April 1, and that Orville Lewis, of Brooklyn, be appointed in his stead. Orville Lewis is a relative of Dr. Lewis. The salary is \$5,000 a year. Dr. F. O'Donohue, chairman of the standing commission on tuberculosis, reported that 527 animals suffering from the disease had been killed since July 15, 1895. The appropriation for the work, \$30,000, he said, was not enough. After the meeting a conference was held with the New York City Board of Health, at which it was agreed to petition the legislature for a larger appropriation in order to deal effectually with tuberculosis.

Opposition, on Sanitary Grounds, to the Ringing of Church Bells at Untimely Hours. Commissioner Dr. Emery, of the Brooklyn Department of Health, having been in the receipt of many complaints of citizens regarding the very early or very prolonged ringing of church bells, he caused to be issued, on February 14, the following note of warning, from the point of view of injury to health to invalids and others resident near churches possessing large bells:

"Notice to the Governing Authorities of Places of Religious Worship Owning and Using Large Bells:—Whereas, frequent complaints have been made to this department against the ringing of church bells at hours, and for prolonged periods, in such manner that it is alleged to be injurious to the health of invalids and others living in the neighborhood of the churches owning such bells, it is incumbent upon me to advise you that section 177 of the sanitary ordinances expressly prohibits the ringing of large bells in such manner as to become a prejudice or peril to the life or health of any human being. All church authorities and others having control over the ringing of large bells in neighborhoods that are thickly settled are hereby requested to prevent the bell ringing before 7 A. M., and in localities where complaints by invalids are brought to their notice, to restrict the bell ringing in the day time to as few strokes as possible."

A Good Way to Get Bad Statistics.—The January *Bulletin* of the Connecticut State Board of Health contains a kind of despairing comment by the secretary, Dr. C. A. Lindsley, on the poor annual vital statistic abstracts that he has to labor over in order to get out his own annual report. The annual abstracts are made up by the town clerks of the various towns, and they are required by law to be sent to the superintendent of registration on or before January 25, in each year. This document is still wanting from three towns. Of the 165 annual abstracts received, 77 have been returned to be corrected, and 12 have been returned the second time. It is quite obvious that any attempt to tabulate the numerous facts in a consolidated form will be blocked effectually, until the numerical

errors in the abstracts are corrected. For instance, if in one table it is stated that there were 9 deaths in May, and in another table that 10 deaths occurred in May, the discrepancy must be removed before the condensed tabulation can proceed. The explanation of these seemingly careless, troublesome and vexatious mistakes is found in the inexperience of town clerks as statisticians. But these many arithmetical mistakes are also indications of still other errors, of which the superintendent has no means of detection. It can not be doubted that in so complicated a matter as summarizing, classifying and tabulating the vital statistics of the population of the State of Connecticut, we have adopted about the worst method that would be thought of. A plan which involves the tabulation of all the original certificates of births, marriages and deaths in the whole State in 168 separate parcels, by as many different persons, nearly all of whom are unfamiliar with such work, does not commend itself to any statistician or promise very accurate results.

Sanitary Considerations Affecting the Tall Office Building. A writer in the *Independent* makes an estimate that the value of the land upon which one of the tall "sky-scrapers" on Broadway, New York city, rests will be at the rate of \$8,000,000 per acre. This explains the development of the huge structures in our cities, and it also explains that financial considerations have outmatched and overmatched those that pertain to health. The writer remarks, first, upon the elements of risk to life by fire, and says: "Considerations of hygiene, esthetics, of the personal rights of others, and of public morals, not being actively represented by anybody, come up slowly and rather feebly. Thus it is already manifest, although nobody is more than mildly impressed by the fact, that the tall office building which New York has rushed of late years into constructing, has risks and problems not yet fully measured. The fire hazard is one of the most serious, and there is no guaranty that the earthquake may not yet be another. Grant that the insufficiency of water pressure is offset by the slow-burning construction, we know that granite and marble are almost as wax in a fierce heat, nothing enduring like brick; the steel skeleton, with its veneer of stone bolted to it, is not so bad as the iron front, but how it will behave under the blast of a great fire is yet to be ascertained. The tall building has also converted the streets, especially the narrow ones, into the likeness of clefts or canyons, through which wind currents rush with exaggerated power. More serious still is the cutting off of daylight from lower floors and from the streets themselves, the sun never more than just visiting them for a few moments, and not doing even that in all places. Viewed from a high point, downtown no longer has streets—there are merely clefts or crevices in the pile of walls. The effect to the eye is startling and suggestive: the consequences, more or less serious, must be in several ways injurious. What is to be done about it? There has been some discussion, and a bill is now before the legislature which proposes to make fifteen times the square root of the street width the limit of height of buildings hereafter to be erected: on a 100-foot street this would make the limit 150. Opposition has appeared already; yet it is plain that if the apparent commercial demand does not continue to prompt the erection of 'sky-scrapers' restriction will not interfere with anybody, and that if this demand does continue restriction of some sort is necessary. In the social state, one can not do quite as he pleases with his own."

The Campaign Against Tubercular Dust.—Dust is becoming as much of a bugbear to the medical profession as it ever was to a model New England housekeeper. A vigorous campaign has recently been inaugurated against dust in hospitals. All angles are tabooed. The walls must have rounded corners where they meet, and where they join the floor and ceiling. The floor should slope to an opening, so that it can be washed with abundance of water or antiseptic solutions. All the furniture

should be of iron, with no ornaments or projections of any kind. No dry sweeping is allowed now. Damp sawdust or something of the kind must be used, and damp cloths to dust the walls and furniture daily. Water should be kept in the cuspidors to prevent the drying of sputa, and the contents carefully burnt. All the water used for drinking and washing hands, instruments, and wounds, should be sterilized. Tarnier has had smooth, sloping, roof-canopies placed over all the old-fashioned furniture, wardrobes, etc., in his hospital in Paris, to collect the dust until it can be washed off. Contagion from tuberculosis in hospitals is just now causing much discussion, and a more vigorous hygiene would be a most efficient aid in settling the question.

The use of sanitary spit mugs in all wards where consumptives are treated, has become a necessity. These are made of thick heavy paper and kept in a frame, from which they are daily removed and burned. This form of spit mug has been used in the U. S. Marine-Hospital service for the past six years.

In the *Medical Press and Circular* for February 19, the Paris correspondent quotes the following statement by Dr. M. Terrier, physician to the Hospital Bichat, that a heavy mortality by tuberculosis has occurred among hospital nurses and attendants. Dr. Terrier says:

"The contagiousness of tuberculosis is a question of capital importance in hospital practice. In many hospitals the phthisical are freely mixed with other patients. I consider tuberculosis extremely contagious. Mathematical proof of this fact can not be given from observation of hospital patients since the disease does not declare itself until after discharge from the hospital, but ample proof is afforded among hospital nurses and attendants at consumption hospitals. Out of twenty-five male and female nurses of the Hôpital Bichat who died in the service, no less than twenty perished of tuberculosis. The contagiousness is further proved by the number of pupils and house surgeons who develop the disease; and it always manifests itself most among those who work hardest and remain longest in hospital. The laboratories have afforded striking evidence; and M. Francois-Franck records the cases of two pupils affected after experimenting with desiccated tuberculous products. There can be no doubt that the dust of apartments where tuberculous patients remain becomes charged with bacilli. Suspected cases should be isolated, and in order to determine the question, an injection of tuberculin ought to be administered. It is only in this way that the dangers of contagion in hospital can be guarded against."

The Vile Yard-vault, or "Midden" still Supreme.—Dr. Francis Vacher, Health officer for Birkenhead, England, in a recent address on the prevention of epidemics urged upon his fellow officers to do their utmost for the *rapid* removal of decomposing animal refuse, as opposed to the primitive and filthy storage of much of it in the back yards of inhabited premises. His remarks are reported in *Public Health* for November. In his opinion, the sanitary needs of the case are hardly met if there is not a daily removal of human excreta. He said:

"From a sanitary point of view, decomposing refuse is of three kinds—1, human excreta; 2, house refuse, and 3, trade refuse. Will anyone assert that the ordinary way of dealing with this material secures its rapid removal? Commonly, the first two kinds are hoarded up in middensteads, in close proximity to inhabited houses; and the third is deposited on wasteland, or turned into a running stream. Much, doubtless, has been done of late to induce manufacturers to use or consume their decomposable waste, and much is still being done. But as for the ubiquitous midden, it is yet supreme. Sanitary authorities rarely attempt its abolition, dissipating their strength in projects for its improvement. It is to be made smaller and shallower, is to be cemented over, and roofed and ventilated, etc. Certainly, you may make it less offensive in this manner, but storing decomposable stuff is an insanitary practice *per se*, and therefore any receptacle for its storage is bad; and improvements, making it a little more tolerable, continue it in existence from year to year. Some recently altered middens are scarcely more tolerable than the most primitive. There are districts where these receptacles are being divided, converting each compound-midden into a midden and cess-pool; and other districts where pails (to be emptied weekly) have been placed under the seats. I can find no smooth word for the

midden, no excuse for those who are content with it. In all its pristine foulness, it is execrable; and, as metamorphosed and modified in various ways, it is yet altogether abominable. Wherever it exists, conditions are present which assist in the spread of many diseases, epidemic and endemic. Where it nestles in the narrow yard of each little dwelling in the poor quarter of a town, who can wonder that the visits of such disease are frequent, and their stay prolonged?

When the invited epidemic comes, attempts are made to discover the cause. It is ascribed to 'the usually neglected condition of the middens,' 'defective construction of the middens,' 'foul water in the middens,' 'overflowing middens,' etc. And what is implied, if not expressly stated, is, that were the middens altered somewhat, or the scavenging improved, all would be right. So the middens are altered, and the scavenging improved. However, when the next outbreak of disease occurs, it spreads. All was *not* right, and never will be, as long as the middens remain. Much of this does not apply to rural districts. Certainly, the daily collection and burning of refuse would not ordinarily be necessary in country places, but checking the practice of hoarding decomposing refuse in contiguity to dwelling-houses is necessary, and can be effected. A compound-midden here and there in the country will not be powerful for harm like long rows of them in crowded towns; but a compound-midden is an odious thing wherever it exists, and should not be tolerated by any sanitary authority."

Health Reports. The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX UNITED STATES.

Ohio: Dayton, February 27 to March 5, 2 deaths.
Michigan: Detroit, March 1 to 7, 2 cases, 1 death; Imlay Township, Ionia, Riga Township and Saginaw, smallpox reported February 22 to 29.
Louisiana: New Orleans February 22 to 29, 53 cases, 2 deaths; Shreveport, March 7, 2 cases.
New York: Brooklyn, January 1 to 31, 1 death.
Texas: El Paso, March 4, 1 case.

SMALLPOX FOREIGN.

Dublin, February 15 to 22, 1 case.
Buda-Pesth, February 5 to 12, 5 cases.
Calcutta, January 18 to 25, 1 death.
Cardiff, February 15 to 22, 4 cases.
Corunna, February 1 to 22, 2 deaths.
Genoa, February 8 to 15, 3 cases, 1 death.
London, Eng., February 1 to 8, 64 cases.
Moscow, February 8 to 15, 1 case.
Naples, February 7 to 14, 29 cases, 9 deaths.
Odessa, February 8 to 15, 1 case, 2 deaths.
Prague, February 8 to 15, 5 cases.
Swansea, February 15 to 22, 2 cases.
Tuxpan, February 15 to 22, 3 deaths.
Warsaw, February 8 to 15, 3 deaths.

CHOLERA FOREIGN.

Bombay, January 28 to February 4, 1 death.
Calcutta, January 18 to 25, 45 deaths.
St. Petersburg, February 8 to 15, 1 case, 1 death.
Japan: Chiba Ken, February 3 to 11, 7 cases.

ASSOCIATION NEWS.

Section on Surgery and Anatomy.

SOUTH BETHLEHEM, PA., Feb. 27, 1896.

To the Editor: We have been fortunate in securing the promise of papers on the special subject for discussion, *i. e.*, "The Surgery of the Cerebro-spinal Axis and Its Bony Encasement," from representative surgeons throughout the country. It is now desirable to have the program completed as soon as possible. Permit me through the medium of the JOURNAL to request all members who desire to present papers on the special subject, or any other branch of surgery, to notify me or the chairman of the Surgical Section, Dr. C. A. Wheaton, St. Paul, as soon as possible. In every case the title of the paper should accompany the request for place on the program.

W. L. ESTES,

Secretary Surgical Section.

Local Committee of Arrangements. The Local Committee of Arrangements for the Atlanta meeting consists of the following:

Chairman, W. F. Westmoreland; Vice-chairman, W. S. Elkin; Secretary, J. McF. Gaston, Jr.; Treasurer, Louis H. Jones. L. B. Grandy, George H. Noble, J. M. Crawford, W. P. Nicolson, A. W. Calhoun, L. P. Stephens, W. L. Champion, Bernard Wolf, C. D. Hunt, B. W. Bizzell, R. R. Kime, W. C. Jarnagin, R. B. Ridley, L. Amster, L. A. Felder, J. C. Olmstead, W. S. Kendrick, J. S. Todd, Hugh Hagan, V. O. Hardon.

SUBCOMMITTEES.

Committee on Ways and Means. Geo. H. Noble, Chairman. W. C. Jarnagin, C. D. Hunt, R. R. Kime, L. Amster, L. B. Grandy, J. M. Crawford.

Committee on Entertainment. W. S. Elkin, Chairman. W. P. Nicolson, B. W. Bizzell, R. B. Ridley, A. W. Calhoun.

Committee on Registration. J. McF. Gaston, Jr., Chairman. L. P. Stephens, L. A. Felder.

Committee on Reception. Hugh Hagan, Chairman. V. O. Hardon, J. S. Todd, Bernard Wolf.

Committee on Exhibits. Louis Jones, Chairman. W. S. Kendrick, J. C. Olmstead, W. L. Champion.

SOCIETY NEWS.

The Tippecanoe County (Ind.) Medical Society at its last meeting elected the following officers: President, Dr. R. S. Tea; Vice-President, Dr. B. Wetherill; Secretary, Dr. Geo. F. Keiper; Treasurer, Dr. Geo. F. Beasley; Censors, Drs. G. K. Throckmorton, W. R. Moffit, E. C. Davidson. The laboratories of Purdue University are thrown open to the profession. In the last six weeks Dr. Bitting, of the University, has lectures on experiments with tuberculin on cattle, and Professor Burrage, the sanitarian, on typhoid fever. On March 16, Professor Duff will demonstrate the cathode rays to the society. The society is enjoying a prosperous year. Meetings on the first and third Mondays.

New York State Medical Association. The following letter has been issued:

Troy, N. Y., Feb. 29, 1896.

Dear Doctor: The Twelfth Volume of our Transactions is nearly completed, and will be distributed in the near future. It is fully equal to any of its predecessors. To those who were not at the annual meeting, and have not paid dues, I enclose bill for the same.

The AMERICAN MEDICAL ASSOCIATION will meet this year at Atlanta, Ga., on May 5-8. Those who wish to attend should notify me at once, that I may send credentials. To those who do not intend to go to the meeting, and who have not yet joined the AMERICAN MEDICAL ASSOCIATION, I wish to call their attention to the fact that they can join the National Organization at any time. The improved and enlarged JOURNAL OF THE ASSOCIATION is now well worth the annual fee of five dollars. Blanks for application can be obtained of me. I hope our membership in the national body will be materially increased this year.

I wish also at this time to request each one intending to read a paper at our Annual Meeting in October to send the title at an early date to me, or to the chairman of the Committee of Arrangements, Dr. J. G. Truax, 17 E. 127th Street, New York City.

Our meetings can only be made as successful as we could wish by personal attendance, securing the attendance of others and contributions to the scientific work. I bespeak your active interest in our Thirteenth Annual Meeting.

Sincerely,

E. D. FERGUSON, Sec'y and Treas.

Third International Congress of Dermatology to be held in London, August 4 to 8, 1896. Tuesday, August 4, preliminary business. Presidential address, "Prurigo," Dr. Besnier, Paris; Dr. J. C. White, Boston; Prof. Kaposi, Vienna; Dr. Payne, London.

Wednesday, August 5, Clinical demonstration of cases, "The Etiology and Varieties of Keratosis," Dr. Unna, Hamburg; Prof. V. Mibelli, Parma; Dr. H. G. Brooke, Manchester; Dr. W. Dubreuilh, Bordeaux. "Syphilitic Re-infection,"

Prof. Fournier, Paris; Mr. Alfred Cooper, London; Prof. Lang, Vienna; Dr. Fitzgibbon, Dublin.

Thursday, August 6. Clinical demonstration of cases. "The Connection of Tuberculosis with Diseases of the Skin other than Lupus Vulgaris," Dr. J. Nevins Hyde, Chicago; Dr. Radcliffe Crocker, London; Dr. Hallepeau, Paris; Dr. J. Riehl, Vienna. "The Duration of the Period of Contagion of Syphilis," Mr. Hutchinson, London; Prof. Lassar, Berlin; Prof. Campana, Rome; Dr. Fuelard, Paris. "Ringworm and the Tricophytons," Dr. Sabouraud, Paris; Prof. Rosenbach, Göttingen; Mr. Malcolm Morris, London. Many contributions to this debate promised.

Friday, August 7. Clinical demonstration of cases. "The Nature and Relations of the Erythema Multiform Group," Prof. De Amicis, Naples; Dr. P. A. Morrow, New York; Dr. T. H. Viel, Stuttgart; Dr. Stephen Mackenzie, London. "Malignant Syphilis," Prof. Handlung, Copenhagen; Prof. Neisser, Breslau; Prof. Tarnovsky, St. Petersburg.

Saturday, August 8. Clinical demonstration of cases, followed by papers.

NOTE. The Congress has been fortunate enough to secure for its use the building known as Examination Hall, on the Victoria Embankment. This will afford every facility for all kinds of demonstrations, cases, pictures, museum, etc. Special efforts are being made to have large demonstrations of cases, and all who have been in London know how rich is the material there. It is of the greatest importance that those intending to join the Congress should notify the Secretary, Dr. J. J. Pringle, 23 Lower Seymour Street, London, W., of their intention as soon as possible. The membership fee is \$5, which should be sent in the form of a one pound sterling draft on London, or P. O. order to the same amount.

GEO. THOS. JACKSON, 14 East 31st St., New York.
Secretary for the United States.

The Medico-Legal Society of Chicago.—A regular meeting was held in Handel Hall, March 7, 1896, with the President, DR. E. J. DOERING, in the chair.

DR. D. R. BROWER, chairman of the committee appointed to present resolutions on the papers presented at the last meeting on "The Habitual Criminal," made the following report, which was adopted:

Mr. President and Members of the Chicago Medico-Legal Society:

Your committee, appointed to consider the papers and addresses presented at the last meeting of the Society on "The Habitual Criminal," after due consideration of these productions and a review of the subject generally, beg leave to submit the following report:

1. That crime is increasing. A comparison of the census of 1850 with the census of 1890, shows that the population has increased 170 per cent, and criminals 445 per cent.

2. As causes of this increase in crime we find vicious parentage and bad environments; as important contributing factors, intemperance, a constant increase in the urban population, unrestricted immigration, and the unreasonable manner in which laws are administered.

3. We regard the habitual criminal as an abnormal man, this abnormality manifesting itself 1, physically, by stigmata in cranial and cerebral development; by criminal physiognomy; by anomalies in the muscular, respiratory and cardiac circulatory systems; by anomalies in motor activity and in physical sensibility; and 2, psychically, by moral insensibility; by a lack of forethought; by a low grade of intelligence; by his vanity; by his emotional instability, and by his slang.

4. The proper treatment of the habitual criminal is a medico-legal question, and not purely a legal one. As a general proposition, the social and biologic conditions of the prisoner, and not the accident of the crime, should determine the degree and kind of punishment.

For the diminution of crime we suggest that there should be radical modifications in the laws. 1, marriage should be regulated. The marriage license, in addition to the present requirements, should demand evidence that both the parties are in

good health; that they are not alcoholic nor narcotic inebriates; that they are not tuberculous, or epileptic; that they have not active venereal disease; that they are not sexual perverts; that they are not insane, criminals, nor paupers. 2, the courts should appoint suitable custodians for neglected children. 3, the pardoning power should be taken out of the hands of the governors of States and placed under the control of a Board of Pardons, who should be skilled in criminal anthropology. 4, in certain special cases asexualization may be indicated or, at least, is worthy of serious consideration. 5, there should be four classes of institutions in which criminals should undergo detention and treatment: Local jails for the retention of prisoners awaiting trial, in which segregation should be complete; reform schools for minor children; reformatories for older criminals who can be reformed; penitentiaries for the life-long incarceration of the incurables.

D. R. BROWER, M.D.,
JAMES BURY, M.D.,
G. FRANK LYDSTON, M.D.,

Committee.

DR. G. FRANK LYDSTON contributed a paper entitled "A Discussion of some of the Fallacies of our Last Symposium."

The paper was freely discussed, after which the Society adjourned.

NECROLOGY.

HIRAM CORSON, M.D., of Plymouth Meeting, Pa., the oldest member of the AMERICAN MEDICAL ASSOCIATION, died March 4. He was born in Plymouth, Oct. 8, 1804 and was descended on the paternal side from the Huguenots, and on the maternal side from the Quaker Dickinsons of England. He was educated at Friends' schools at Plymouth Meeting and Philadelphia, and was graduated from the medical department of the University of Pennsylvania in the spring of 1828, at which time he settled in Plymouth Meeting. He was a member of the Philadelphia Medical Society; of the Montgomery County Medical Society, of which he was president in 1849; of the State Medical Association, of which he was president in 1852; and of the AMERICAN MEDICAL ASSOCIATION since 1847. He was elected a member of the Meigs and Mason Academy of Medicine in Ohio, in 1873; associate member of the Philadelphia Obstetric Society in 1874; and associate Fellow of the College of Physicians of Philadelphia in 1876. His contributions to medical literature include papers on "Epidemic Jaundice"; "Belladonna in Pertussis," and "Measles," also numerous papers addressed to the State Society on "Ice in Scarlet Fever and Diphtheria, Externally and Internally," (a treatment of which he was the originator); on "Food for Infants;" on "Erysipelas following Vaccination;" on "Midwifery in the Country," and many other subjects, beside various contributions to medical journals.

SMITH ELY, M.D., for many years a leading physician and surgeon in Newburgh, N. Y., died February 28, of heart disease, 68 years old. He studied medicine in New York and Woodstock, Vt., graduating from the Vermont Medical College in 1850. For a time he was one of the resident physicians at the Emigrants' Hospital, Ward's Island, and afterward made several voyages as surgeon on the steamer *Franklin*, between New York and Havre. He had been a director of the Highland National Bank since 1875.

JAMES WOODWARD ELLIOT, M.D., of New York city, died February 28. He was 72 years old, was born in England and came to this country with his father's family when quite young. He was graduated in 1850 from the New York College of Physicians and Surgeons. Only two members of his class are now alive. He began his practice in old Greenwich Village, at No. 11 Abington Square. There he conducted a general practice until thirteen years ago, when he moved to the house in Fourteenth Street, where he died. For twenty years he was connected with the City Mission, and superintendent of the Sunday school of St. Barnabas' chapel. He had been an enthusiastic member of the old New York Cricket Club on

Staten Island. He remained English in his sympathies all his life. He leaves two sons and one daughter.

WILLIAM J. PURCELL, M.D., of New York city, one of the oldest vaccinators in the public schools, and one who had held a place with the Bureau of Contagious Diseases since May, 1875, died on February 17. He was an alumnus of Bellevue Hospital Medical College, class of 1867. He was a member of the County Society and the Society for the Relief of Widows and Orphans of Medical Men, also of the Medico-Legal Society. He was a man of great geniality of disposition, and had a host of warm friends in and out of the profession.

HENRY H. HOUSE, M.D., postmaster of Rockland Lake, N. Y., and for years the only resident physician there, died February 21, from injuries received by being struck by an engine on the West Shore Railroad, at Congers. His skull was fractured and he remained unconscious until his death. Dr. House was about fifty-five years old, and was born in Ulster County. He received his medical diploma in 1863, at University Medical College, and had lived in Rockland Lake since 1874. He was prominently identified with many interests in the country, being a school trustee and health officer. He leaves a widow and two sons.

DAVID L. DAGGETT, M.D., died of pneumonia on February 23, at his residence, in New Haven, Conn. He was born June 24, 1820, in New Haven, where his father and grandfather were also born. The grandfather, Judge David Daggett, was mayor of the city, a senator of the United States, professor of law in Yale and judge of the superior court of Connecticut. Dr. Daggett graduated from Yale in 1839 and went to Virginia, where he taught school. He graduated from the Yale Medical School in 1843, and was assistant surgeon and surgeon at the Old Knight Hospital. He has been president of the New Haven and County Medical Associations, and a member of the State Medical Society. Dr. Daggett was married in 1848, to Margaret, daughter of Dr. Wilbur Gibbons, of Wilmington, Del. Mrs. Daggett died in 1865. He leaves three sons, David, Dr. W. G. and L. M. Daggett, all of New Haven.

ASHBEL W. BARROWS, M.D., of Hartford, Conn., who died early in January, 1896, was the medical director of the Phenix Life Insurance Company. He was born at Mansfield, in that State, in December, 1816. At the age of 21 he entered Yale Medical School, and graduated in 1841. He first practiced at Rocky Hill, and removed to Hartford in 1847, where he has since resided. He was one of the six original physicians of the Hartford Hospital, which was founded in 1857. He was a visiting physician until 1874. Since then, up to the time of his death, he was one of the consulting physicians. In 1851 he became connected with the Phenix Mutual Life Insurance Company as assistant medical examiner. In 1853 he was appointed medical director of the company, a position which he held until his death. He was a member of the State, County and City Medical Societies. Of the two former societies he was president at different times, and of the latter he had been vice-president for the past two years. He was an early member of the AMERICAN MEDICAL ASSOCIATION, having united therewith in 1853.

HERBERT JAMES SAUNDERS, M.D., of Kingston, Ontario, died February 16, in his fiftieth year. He had been ill for six weeks with septic pneumonia. Dr. Saunders held the chair of clinical medicine and dermatology in Queen's University Medical Department. He was a surgeon-major in the Canadian Militia, and was considered one of the ablest Canadian physicians. He held the degree of M.R.C.S.E., from the year 1870, as well as that of M.D., from the Queen's University. In the College of Physicians and Surgeons of Ontario, he was in 1892 and 1893 a member of the Board of Examiners, taking the subject of the Theory and Practice of Medicine.

WILLIAM O'MEAGHER, M.D., a New York city coroner, died February 21, after a rapidly progressive attack by pneumonia.

Dr. O'Meagher was born in Ireland sixty-five years ago. He graduated in arts from Queen's College, Galway, Ireland, and graduated as a physician from the Medical Department of the University of New York in 1857. He served as a surgeon of the Sixty-ninth regiment for four and a half years during the civil war. He was a member of the Medico-Legal Society, the Harlem Medical and Chirurgical Society and the New York Academy of Medicine. At one time he was house surgeon and physician in St. Vincent's Hospital, a physician in the New York Dispensary and a health inspector of Richmond county and New York city. He leaves a daughter, Mrs. Eveline Donohue, and four grandchildren.

MISCELLANY.

Care of the Feeble Minded in Denmark.—The private establishments for this purpose in Denmark have received an allowance from the government until recently, when a law was passed to transform them into state institutions.

"A Cocada." The Peruvian Indians have as a measure of distance the cocada, which means the ground a cargo-bearer can walk under the stimulus of one quid of this leaf—the impulse lasts from thirty to forty minutes, and a man can pass over three kilometers.

Wafers: Light and Red.—Man's faith in human knowledge is illustrated in the picture of the bald-headed physician prescribing for baldness in a patient. As long as the world lasts, people will trust in the power of medical science to restore lost tissue.

He Had Previously Complied. The black-bearded pirate, with a knife between his teeth, boarded the passenger ship. "Throw up your hands!" he shouted. The passenger hanging over the rails smiled feebly: "I think I did, not less than an hour ago," he said gaspingly.

Pennsylvania Prohibits Exhibitions of Deformities.—An act was passed in Pennsylvania in 1895 making it unlawful, and affixing a heavy penalty for any person to exhibit in any public hall, museum, theater or any other building, tent, booth or public place for a pecuniary consideration or reward, any insane, idiotic or deformed person, or any imbecile.

Bacillus Pyocyaneus in Urine.—Le Noir reports a case of urinary calculi and pyelitis in a young man, in whose urine were found the bacillus pyocyaneus and the bacterium coli. Pyocyanin was extracted with chloroform from the bouillon in which the cultures of the bacillus pyocyaneus had been made.—*Gaz. Méd. de Paris*, February 1.

Draining Lake Texcoco.—We have received from the Department of the Interior of Mexico an interesting series of charts and diagrams in regard to the great enterprise of drying up Lake Texcoco, near the city of Mexico. The sewers of the city have drained into it from time immemorial, but the completion of the new canal and tunnel will empty it almost entirely of water, and reclaim the land for agriculture, which is considered an important sanitary measure.

Iron Stairways on Outside of Hospitals. Taking effect Oct. 1, 1895, it is required by law in New York State that all hospital buildings used for general hospital purposes, or hospitals or asylums for the insane, or any hospital or buildings which are more than two stories high, other than those which are fire-proof in their construction shall have properly constructed iron stairways on the outside thereof, with suitable doorways leading thereto from each story above the first, for use in case of fire.

Large Bequest to a Philadelphia Hospital. The will of the late Mrs. Anna R. Aspinwall, of Pittsburg, Pa., who died in Edinburgh, Scotland, last December, leaves her entire estate, estimated to be worth from \$1,000,000 to \$3,000,000, to the Hospital

of the Protestant Episcopal Church, Philadelphia. This hospital is maintained for the benefit of white female sick or convalescent orphan children. The will stipulates that there shall be no denominational discrimination, and asks that preference be given to children who have lost both parents. A contest of the will is threatened, but the presumption in favor of its validity is said to be very strong.

Anti-venom Serum.—Animals inoculated with Calmette's anti-venom serum, and then exposed to be bitten by venomous serpents, are found to be immune. Until recently no experiments had been made on human beings, but Dr. Lépinay, of Saigon, reports a life saved with it. An Annamite who had been bitten by a *naja tripudians* was inoculated with the Calmette serum an hour afterward, and recovered. Calmette is at the head of the Pasteur Institute at Lille.—*Nord Médical*, February 1.

Tetanus Accompanied by Exophthalmic Goitre.—Steinlechner describes in a Vienna exchange a case of tetanus and Basedow's disease in a young woman, beginning with painful cramps in the extremities. Tracheotomy was performed to prevent death from suffocation, and death followed from an intercurrent purulent bronchitis, about a year after first symptoms developed. The necropsy disclosed exophthalmic goitre with dilatation of the heart, bronchial and pulmonary lesions, and also acute gastritis and enteritis, with an acute hemorrhagic nephritis.—*Gaz. degli Osp. e Clin.*, January 28.

The Charity Club Hospital of Boston.—The building, located on the top of Parker Hill, Roxbury, has a fine outlook and an abundant areation. It is in the charge of Dr. Elizabeth T. Gray, a graduate of the Woman's Medical College of the New York Infirmary, and her assistant superintendent. Beside these, the staff consists of a housekeeper and corps of eight servants, a head-nurse and ten under-nurses, a staff of six prominent surgeons attend the operations, each on their allotted service. The hospital wards contain from twenty to twenty-five beds, usually all occupied. Dr. Gray has also a training school for nurses.

Formol as a Preservative of Laboratory Specimens.—The Société des Sciences Méd. de Lille devoted some time at a recent meeting to endorsing formol as a cheap and effective preservative of macroscopic pieces. It penetrates, hardens and preserves tissues without retraction, without staining or injuring instruments or any caustic effect on the skin. One to 100 is a strong enough solution for most specimens, but especially fragile ones can be put in a 2 to 4 per 100. A weak solution is especially valuable in preserving urine. It also prevents the transformation of urea into ammonium carbonate, and the only disadvantage it has is that it turns blood a grayish color. *Nord Médical*, February 1.

Improved Preventive.—Weisel presented an article at a recent meeting of the Medical Association at Prague, first remarking that since the Medical Congress at Amsterdam, when Drysdale first publicly announced that there were occasions when a physician was justified in supplying a patient with some means to prevent conception, many devices have been invented, but none have proved reliable except Mensinga's pessarium. Even this has the disadvantage that it can only be inserted by a physician. Weisel's invention is similar to this, but is made so simple and so strong that no skill is required to introduce it. It consists of a hollow rubber cone and rubber disc connected by a spring. The disc fits tight in the vagina, which it closes completely, without inconvenience of any kind. Waldek and Wagner, of Prague and Vienna, are the manufacturers *Wiener klin. Rundschau*, February 9.

"White Salt" in Congo-land.—According to the *Independent*, the following estimate of the value of salt in Central Africa, and especially in the interior of the Congo Free State, is derived from the letters of a medical man who has recently been traveling in Congo-land. He says that of all the white man's pos-

sessions, the one most coveted is "white salt," so called to distinguish it from the home product, which is a sort of black cinder-like substance, and so scarce as to cause much suffering. There are many parasitical diseases, both external and internal, caused by this lack. If a white man gives them a spoonful, it is most carefully divided, and if in the distribution there has been a miscount, the "overlooked" man will lick the palm of the hand in which the original treasure lay to secure the last grain. Some poorly informed person lately produced an article called, "Why salt?" in which he fancied he made out a case of man's going without salt. He had little physiologic knowledge and had never read how the entire deprivation of salt ruins animals.

Mastoiditis and Otitis. Ueherman read a paper recently before the Congrès des Chir. du Nord on suppurating inflammations of the ear, in which he advocated prompt surgical intervention whenever the pain, edema and fever accompanying acute inflammation of the mastoid cavity and cells fail to yield to antiphlogistic and local treatment. 2, in chronic mastoiditis with repeated tumefactions, fistulas or abscesses. 3, in acute suppurative inflammation of the middle ear when fever keeps up after tympanum has been punctured. 4, in similar cases that have become chronic and are accompanied by fever when flow ceases. 5, in tumors of the connective tissue with caries of the apophysis, which it is impossible to reach and treat through the natural passages. 6, in chronic fetid otorrhea which will not yield to local treatment, especially if complicated with cerebral disturbances. *La Province Médicale*, January 4.

Antitoxin in Bordeaux. Bordeaux has reduced the annual death rate from diphtheria from 103.43 to 18 by its fine antitoxin service. A set of culture tubes, nickel spatula and circular of directions are given free to any physician who applies for them at any of the numerous sub-stations, when he has a case of suspected diphtheria. He makes the culture and sends the tubes to the central laboratory where they are examined by an expert. If diphtheria bacilli develops in the tubes the latter sends immediately, at the expense of the city, sufficient antitoxin for the physician to treat the case properly. Seven hundred and eighty-nine cultures were made last year, 389 of which proved to be diphtheria. In this way the antitoxin was not wasted, nor inflicted on any except those who actually required it. Five horses supply the serum. *Bulletin Médical*, February 5.

Provision in New York as to Hydrophobia.—There was a law passed in New York in 1895 which provided that overseers of the poor, or other officers having charge of the dispensation of public charity in the several counties of the State should send to the Pasteur Institute in the city of New York all persons duly certified by regular physicians to have been bitten by rabid animals or otherwise put in danger of infection with rabies. The transportation of such persons, with necessary attendant or attendants, to and from the city of New York, shall be a charge upon the counties in which they reside. The sustenance, nursing and preventive treatment of such persons, for the time adjudged necessary, shall be provided by the Pasteur Institute. An appropriation of \$6,000 was made to compensate the institute for the services named. It is also required to be at all times open to the inspection of the governor and of the State board of health or of the accredited representative of either, and it is to annually make a report to the legislature.

Lectures of Benjamin Rush. Rush Medical College, Chicago, has recently come into possession of a volume of notes in the handwriting of a medical student who attended the lectures of Dr. Benjamin Rush in 1784. The volume, quite antique and dilapidated in appearance, contains 278 pages written in a clear hand, and presents a brief outline of the symptoms of disease

with the modes of treatment as conducted by the distinguished lecturer. Scribbled on several of the pages are various opinions, quotations and considerable matter irrelevant to the subjects of the lectures. Advice to students as regards to character, behavior, dignity, and avoidance of quackery, seems to have been as needful a century ago as now. A lecture is devoted to this subject. This interesting volume was for many years early in the century, the property of Dr. John K. Briggs, of Dedham, Mass., and was presented to Rush Medical College through Charles C. Hyde, Esq., by Dr. F. M. Briggs, of Boston.

Expert Opinions as to the Future. Every expert opinion as to the future, founded upon present conditions, is, and must necessarily be, uncertain; but the fact that it is so uncertain, the supreme court of the State of Washington holds, in the case of *Mitchell vs. Tacoma Railway and Motor Co.*, decided Jan. 30, 1896, does not prevent the opinion of an expert being given as to the probable results.

Thyroid Treatment for Obesity and Stunted Growth. At the meeting of the Société de Biologie of January 18, Bourneville reported several cases of obesity and stunted growth in children treated with thyroid glands. The loss of flesh was rapid for a while, and then the treatment seemed to lose all efficacy, but the dwarfed children showed a marked increase in height under the influence of the thyroid treatment. He was induced to try the thyroid treatment by observing its effect on three cases of myxedematous idiocy. — *Gaz. Méd. de Paris*, February 1.

Evidence Admitted to Show Pain.—In an action brought to recover damages for personal injuries to feet, legs, side, back, spine and womb, by which it was alleged that the plaintiff became sick, very lame, diseased and disabled, and suffered great pain, the supreme court of Michigan holds that it was proper to admit her testimony as to pains in her head and stomach, not to prove injuries to the head and stomach, but as showing the pain suffered from the injury to other members. The court also holds, in the same case, *Will vs. Village of Mendon*, decided Feb. 7, 1896, that while the husband could not testify to a sensation experienced by the wife, he might testify to her complaints and statements as to the location, nature, and extent of her pain and suffering made at the time she was feeling the pain, and as to a numbness of her arm, as observed by him.

Abnormal Secretion of Sulphur in an Experiment on a Dog.—Smith Jerome writes to *Pflüger's Arch.*, No. LX, p. 233, describing some experiments with a dog, fed only with dog-biscuit and water, to whom he administered ethylsulphid and potassium carbanthio-glycolate. With the former 66.5 of the total amount of sulphur was oxydized into sulphuric acid. After the potassium carbanthio-glycolate was administered the total fell to 68.4 per cent., remained 66 per cent. for four days, and fell to 50 per cent. before the ethylsulphid was given again. It remained at this low figure during this period and for more than two months afterward, when calomel and jalap were administered causing it to rise to 70 per cent. The proportions between the total amounts of sulphur and nitrogen were altered in that the increase in the amount of sulphur was not only relative but absolute. It was all in the neutral form, however. Jerome queries whether the proportion of neutral to oxydized sulphur in the urine may not be less constant than we suppose, and suggests that the secretion of sulphur may serve as a means to determine the amount of albumin decomposed in the organism. — *Centralblatt für Phys.*, Oct. 5, 1895.

Wounds in Modern Warfare. Professor Delorme read a paper on the wounds produced by modern firearms at close range, before the meeting of the Paris Acad. de Méd. of January 27, which concluded as follows: 1. The shock from the small bullets (Lebel), now eight millimeters instead of eleven, is not so great as it used to be from larger balls. 2. The holes through

which the bullet enters and passes out are smaller, and the hemorrhage proportionately less. 3. Particles of clothing are usually carried with it into the wound, but they are eliminated with the pus, which they discolor. 4. The new bullets usually fly to pieces when they strike a wall or hard substance, and the flying fragments produce special injuries. Professor Delorme had peculiar facilities for studying this class of wounds, as he took charge of the injured at Fournies fifteen days after the affair. They were all struck by Lebel balls within a range of 100 meters. Eight were killed outright, but the other thirty-four wounded all recovered in spite of apparently desperate injuries. He closed by remarking that if the general health of the soldiers is carefully looked after, so that it will second the efforts of nature and the surgeon, modern warfare is not as destructive as is supposed. — *Bulletin Médical*, February 5.

Pennsylvania Physicians must Report Infectious Diseases.—A law passed in Pennsylvania in 1895 provides that every physician located or practicing in any of the municipalities of that commonwealth, who shall know that any person whom he or she is called upon to visit, or who comes or is brought to him or her for examination, is suffering from, or is afflicted with cholera, smallpox (variola or varioloid), diphtheria, diphtheritic croup, membranous croup, scarlet fever, typhoid fever, typhus fever, yellow fever, epidemic cerebro-spinal fever, relapsing fever or leprosy, shall forthwith make report in writing, or upon blanks to be furnished for that purpose, to the health authorities of the municipality in which said person may be located, which said report shall be over his or her own signature, state the name of the disease, and the name, age and sex of the person suffering therefrom and shall also set forth by street and number, or otherwise sufficiently designate the house, room or other place in which said person may be located, together with such other information relating thereto as may be deemed important by said health authorities. In case of all of the above diseases, except typhoid fever and epidemic cerebro-spinal fever, it is provided that the health authorities may have placards giving name of disease placed on or near house, or place guards upon the premises. The duties of undertakers are prescribed by the same statute, which also provides for private funerals and advertisements stating cause of death, etc.

Dr. Jenner's Midwinter Ride in 1786.—The London *Lancet* brings to light a letter written by the immortal Jenner in January, 1786, that shows by how narrow a margin the discoverer of vaccination escaped an untimely death by cold and exposure, in which we call now-a-days a "blizzard." The letter runs as follows:

"JANUARY 3, 1786. — I was under the necessity of going from hence (Berkeley) to Kingscote. The air felt more intensely cold than I even remembered to experience it. The ground was deeply covered with snow and it blew quite a hurricane, accompanied with continual snow. Being well clothed, I did not find the cold make much impression upon me until I ascended the hills, and then I began to find myself benumbed. There was no possibility of keeping the snow from driving under my hat, so that half my face and neck was for a long time wrapped in ice. There was no retreating, and I had still two miles to go, the greatest part of the way over the highest downs in the country. As the sense of external cold increased, the heat about the stomach seemed to increase. I had the same sensation as if I had drunk a considerable quantity of wine or brandy, and my spirits rose in proportion to this sensation. I felt, as if it were, like one intoxicated, and could not forbear singing, etc. My hands at last grew extremely painful, and this distressed my spirits in some degree. When I came to the house I was unable to dismount without assistance. I was almost senseless; but I had just recollection and power enough left to prevent the servants bringing me to a fire. I was carried to the stable first, and from thence was gradually introduced to a warmer atmosphere. I could bear no greater heat than that of the stable for some time. Rubbing my hands in snow took off the pain very quickly. The parts which had been most benumbed felt for some time afterward as if they had been slightly burnt. My horse lost part of the enticel and hair at the upper part of the neck, and also

from his ears. I had not the least inclination to take wine or any kind of refreshment. One man perished a few miles from Kingscote at the same time and from the same cause."

The comment of the *Lancet* on the foregoing is as follows: The correspondent who sent us the above extract from a letter of Edward Jenner, being a medical man, must feel, as we do, grateful that January, 1896, has not opened with the rigor of January, 1786. We print it because it paints a remarkably true and vivid picture of the alteration of sensation under the influence of extreme cold.

One hundred and twenty-five days later, on May 14, Dr. Jenner vaccinated a boy of eight years, with lymph taken from a vesicle on the hand of a dairymaid, and six weeks later he inoculated the same boy with the virus from smallpox. The experiment shows the protective influence of the lymph, and in June, 1798 an account was published of the greatest life-saving experiment the world has yet seen.

Waiver of Privilege as to Consulting Physician. On an appeal from a judgment obtained against a railway company for personal injuries, the only question involved arose upon exceptions taken by the company's counsel to the exclusion of certain evidence, offered by him, bearing upon the extent and nature of the plaintiff's injuries. About the time of the commencement of the action two physicians attended the plaintiff for the purpose of making an examination of her case. She called one of them as a witness in her behalf at the trial. His testimony tended to show that she was affected with some spinal trouble as the result of a railway accident. His opinion was based mainly upon the result of the personal examination which he made upon the occasion referred to with his associate physician. But the plaintiff did not call the other physician to testify, and the defendant company did, and propounded to him certain questions, intended to elicit his opinion as to the nature and extent of the plaintiff's injuries from his observation of her person on the occasion of the examination. These questions were all objected to as inadmissible, and the court sustained the objection. The court of appeals of New York, however, takes a different view of the matter, in a decision rendered Dec. 19, 1895, *Morris vs. New York, O. & W. Ry. Co.*, and reverses the judgment given. First of all, it holds that the relation of physician and patient existed. Then, it declares that a construction of the statute which permits a patient who has been attended by two physicians at the same examination or consultation to call one of them as a witness to prove what took place, or what he learned, thus making public the whole interview, and still retain the right to object to the other, is unreasonable and unjust, and should not be followed. The waiver is complete as to that consultation when one of them is used as a witness. The considerations and reasons upon which the statute was founded no longer exist when full disclosure is made by either with the consent of the patient, and every party to the transaction thus disclosed is relieved from any injunction of secrecy. The patient can not limit the scope or effect of the waiver when made any more than she can recall it. When the plaintiff in this case called one of the physicians, who disclosed the whole consultation, the law determined the legal effect of that act, irrespective of any mental reservations on her part. Upon every principle of reason and justice this act amounted to a waiver of the right to object to the testimony of the other physician, when called by the defendant, as to the same transaction. For these reasons, the court thinks that the testimony excluded was admissible, and holds as already stated.

Practical Notes.

Non-tuberculous Ulcers in Tuberculous Patients.—Claude reports two cases of ulcerous condition of the tongue in consumptives, neither of which were produced directly by the Koch bacillus. One was a granulated process, and the other caused by secondary microorganisms in the mouth of a cachectic. —*Gaz. Méd. de Paris*, February 1.

Dr. Willems of Ghent. Our French exchanges mention the recent death of Dr. Willems of Ghent, and recall his services during the Franco-Prussian war, when he devoted himself to the care of the wounded, sharing in all the hardships and dangers of the campaigns, and only returning to his home in Belgium when incapacitated by illness.

Bite of Jackal, Probably Rabid. One of the successful cases that fell under the treatment of the Institut Pasteur, at Paris, in 1895, was that of an Englishman, formerly resident near Calcutta, Bengal, who had been bitten by a jackal. The injured person hurriedly left India, by the advice of his physicians in Calcutta. As the bite was received while the patient was in camp, it could not be determined that the jackal was rabid, but that was the belief of the onlookers. About a year later the patient was reported to be in excellent health.

Cetrarin. According to Kobert, cetrarin, the active principle of the *lichen islandicus*, stimulates the peristaltic action of the stomach and the bowels, increases the number of the blood corpuscles in cases where they have diminished in the course of disease, and is a general tonic for the nervous system. Cetrarin, therefore, is indicated in chlorotic, anemic cases, where there is constipation and loss of appetite. Dose prescribed: one-eleventh gram. —*Progrès Médical*, February 8.

Formalin in Disinfecting Catgut. This journal recently noted the advantages of formalin in preserving macroscopic specimens, as it hardens and strengthens the tissues. Hlavacek now announces that it is exceptionally valuable in sterilizing catgut. It does not kill the bacteria: they emerge unharmed after soaking hours in it, and being exposed to the vapor. But it hardens the catgut so that it will stand boiling. This result is accomplished by soaking it twelve hours in a 5 per cent. solution of formalin, or three hours in a 20 per cent. solution. The catgut can then be boiled twenty minutes without injury. If then it is kept in a 1 per cent. solution of sublimate, it is always ready for use, strong and solid and absolutely sterile. —*Wiener klin. Rundschau*, February 8.

Influences of Temperature on the Digestibility of Foods. Hayem has been experimenting with Ewald's test-meal at different temperatures, and he announces that heat, and especially cold, exert a most important influence on the chemie action of the stomach. They increase the secretion of free hydrochloric acid, and also of the gastric juice, symptoms of hyperemia of the mucous membrane and increased glandular activity. He draws the conclusions that tepid foods should be taken in hyperpeptic dyspepsia, while they should be taken cold in hypopeptic conditions. He intends to publish a series of studies on the processes of digestion at varying temperatures, and hopes that other scientists will coöperate with him in studying them, taking the Ewald test-meal for the basis of their researches. —*Wiener klin. Rundschau*, February 8.

Yersin's Plague Bacillus. The "cocco-bacillus" stated by Yersin to be the cause of the plague can be easily cultivated on gelatinized peptone. It is pathogenic for the rat, mouse, guinea pig and rabbit. By transmissions, bacilli of fixed virulence can be obtained for one kind of animal. But it requires a series of transmissions to acquire a maximum and fixed virulence for another kind. Filtered cultures have no effect upon animals: a large amount of dead bacilli must be injected to secure inoculation. The serum of a horse immunized by intravenous injections will immunize other kinds of animals. No other serum has any effect on the development of the disease, as was demonstrated by many tests with the normal serum of the horse, the anti-diphtheria serum, Marmorek's serum, Roux's anti-tetanus serum and Calmette's anti-venom serum. —*Nord Médical*, January 15.

Treatment of Imperfect Circulation. Bum's essay on the mechanical-gymnastic treatment of disturbances in the circulation is given at length in the *Wiener klin. Rundschau*, of February 9.

He advocates massage of the extremities and of the neck, and places great emphasis on the benefit to be derived from deep breathing, which draws the venous blood upward to the heart by means of the differences in pressure in the thoracic cavity. He insists that exercise and rest must strictly alternate. Gymnastic exercise should coincide with the systole of the heart, and be commenced with apparatus offering the least resistance. Further treatment is the shaking of the heart and the thorax, thumping on the region of the heart and spine, until the whole thorax vibrates. Also passive exercises calling the large joints into play. This treatment is contra-indicated in arterial aneurysms and sclerosis and also in degeneration of the myocardium. The best results are obtained where there is a general lack of tone in the circulation, and in hypertrophy and incipient fatty degeneration.

Treatment of Night Sweats in Phthisis.—The *Nouveaux Remèdes* gives the following prescriptions for night sweats in tuberculosis:

R. Fowler's solution 3 grams.
Tinct. of belladonna 3 grams.
Water of bitter almonds 20 grams.

Misce. Take xv xx drops of this solution about 5 P.M.

R. Codein 0.5 grams.
Dist. water 120.0 grams.
Simple syrup 20.0 grams.
Alcohol 10.0 grams.

Misce. Take a tablespoonful about 8 P.M.

R. Hydrated chloral 6 grams.
Dist. water 100 grams.
Alcohol 100 grams.

Misce. Rub the body with this before retiring.

Louisville Notes.

"SPOTTED FEVER."—Dr. Cashin, the State bacteriologist, in his report to the State Board of Health in regard to his visit to Edmonson County, states that in all there have been thirty-three cases, ten have died, and fifteen are now under treatment. The type of the disease is much milder now than when it first made its appearance, some six weeks ago. The first case developed in the person of a young man who had not been out of the county for months. One autopsy was made by Dr. Cashin and cultures made of cerebro-spinal fluid, the details of which are not yet complete.

Excitement is high in Wolfe County on account of a death from spotted fever. Several other cases are reported, and it is feared another outbreak such as occurred in Edmonson County will prevail.

PHARMACY LAWS. By a recent enactment of the legislature the very comprehensive laws governing the practice of pharmacy have been made to be effective in every county of the State.

DEATH REPORT. There were 66 deaths during the past week, 40 male and 26 female. Pneumonia caused 6 deaths. There were 8 cases of diphtheria placarded and three cases of scarlet fever.

LEGISLATIVE ACTS. In addition to the pharmacy laws being extended the legislature appropriated \$100,000 to establish two houses of reform, one for boys and one for girls. This is a much needed measure.

A favorable report was also made upon the bill to provide coroners in certain counties with stenographers.

Detroit Notes.

THE CHILDREN'S FREE HOSPITAL ASSOCIATION has just sent out its ninth annual report. The medical staff has been enlarged and is complete as follows: Medical staff: Drs. C. A. Lavendorf, L. Connor, J. K. Gailey, H. A. Cleland, D. Laferte, Justin E. Emerson. Dental surgeon: Dr. E. M. Thompson. Assistant physicians: Drs. R. A. Newman, A. P. Biddle. Consulting staff: Drs. Donald Maclean, G. E. Frothingham, C. G. Jennings. Outdoor Department: Director and physician, Dr. Wm. F. Lyster. Surgeons: Drs. J. K. Gailey, D.

Laferte. Assistant: Dr. W. C. Marten. Ophthalmologist: Dr. A. Turner. Neurologist: Dr. J. E. Emerson. Dermatologist: Dr. A. P. Biddle. House Physician: Dr. P. C. McEwen. In the recording secretary's report we see that there are thirty-three beds kept up by one or more individuals. The treasurer's report shows receipts for the ensuing year \$7,120.40, and disbursements \$6,986.31.

THE WAYNE COUNTY MEDICAL SOCIETY at its regular meeting Thursday, March 5, listened to a paper by Dr. Edward K. Bacon, entitled "Epilepsy," which was principally historical.

AT THE REGULAR MEETING of the Detroit Medical and Library Association held Monday, March 2, Dr. F. D. Summers presented a paper entitled "Pyosalpinx."

HEALTH OFFICE REPORT for week ending Feb. 29, 1896: Deaths under 5 years 35, total 78. Births: Male 56, female 44, total 100. Contagious diseases: Diphtheria, last report 12, new cases 17, recovered 6, died 3, now sick 20. Scarlet fever, last report 15, new cases 4, recovered 3, died none, now sick 16. Smallpox, last report 3, new cases 3, recovered none, died 3, now sick 3.

Health Office Report for week ending March 7, 1896: Deaths under 5 years 40, total 88. Births: Male 60, female 57, total 117. Contagious diseases: Diphtheria, last report 20, new cases 6, recovered 15, died 2, now sick 9. Scarlet fever, last report 16, new cases 5, recovered 6, died none, now sick 15. Smallpox, last report 3, new cases 2, recovered 2, died 1, now sick 2. Measles, last report none, new cases 2, recovered none, died none, now sick 2.

Washington Notes.

THE POST-GRADUATE MEDICAL SCHOOL.—The Board of Directors of the Post-Graduate School of Medicine held their first meeting on March 5, under the charter granted by Congress.

THE WOMEN'S CLINIC.—The Board of Directors of the Women's Clinic held their regular monthly meeting on the 7th inst. in their new home. Important business was transacted and the report of the staff showed the work to be steadily on the increase.

MEDICAL SOCIETY.—At the regular meeting of the Society held on the 4th inst., Dr. Barrie read an essay on the clinical symptoms of renal casts. Dr. Bishop on cerebral hemiplegia, its differential diagnosis and rational treatment. Dr. S. S. Adams reported an interesting case of convulsions in a young child: the first attack was apparently caused by a piece of glass in the stomach, and the second from two beans. Both attacks occurred within two weeks; the child recovered.

WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.—At the meeting of the Society held on the 6th inst., Dr. Stone read an instructive paper on post-operative results in pelvic and abdominal surgery. Dr. Stone presented an appendix and a fibroid removed by abdominal section. Dr. Bovee presented a extra-uterine pregnancy with fetus successfully removed, also a tubo-ovarian cyst. Dr. J. T. Johnson reported a case of hysterectomy for fibroid. Dr. H. L. E. Johnson reported a case of cystic ovary and double salpinx successfully removed.

MEDICAL PRACTICE ACT. The Senate District Committee has favorably reported the House Bill to regulate the practice of medicine in the District with amendment as follows: The bill is to take effect from July 1, 1896, instead of from the date of its becoming a law. The provisions as to admitting to practice physicians coming here from other States is altered to read as follows: A license to practice shall be issued "to physicians who may change their residence to the District of Columbia from any State or territory where medical laws and medical examining boards exist, the presentation of a certificate or license from a medical examining board, if found upon due inquiry to be true and genuine, being sufficient right of registration and certification under the provisions of this act."

It is provided by the Senate amendments that appeals from the board of medical supervisors to the court of appeals, instead of to the Commissioners, in all cases where the names of physicians are stricken from the register.

Cincinnati Notes.

THE MORTALITY REPORT for the week gives: Membranous croup 1, diphtheria 4, measles 6, scarlet fever 1, typhoid fever 4, other zymotic diseases 7; cancer 3, phthisis 19, other constitutional diseases 4; bronchitis 2, convulsions 3, meningitis 6, heart disease 3, nephritis 2, pneumonia 11, other local diseases 28; total 120; under 5 years 40, annual rate 17.82; preceding week 147, corresponding week 1895, 123.

THE BRANCH HOSPITAL is at last to be used as a hospital for tubercular cases. This matter has been agitated for a long time and is undoubtedly a most excellent move. Heretofore the institution has been used for the reception of smallpox cases only and therefore was empty for years at a time. It is beautifully located about eight miles from the city on one of the highest points, and the buildings are well adapted for isolation purposes. The staff is to be selected from those members of the profession who have made this disease a careful study.

THE ANNUAL REPORT of the Ophthalmic Hospital shows: Admissions 2,286; in-door 107; dispensary 2,179; total dispensary attendance 10,909; average daily attendance 35; major operations 154; minor operations 218.

DR. PRENDERGAST, the Health Officer, is endeavoring to have the cases of contagious diseases isolated, and recommends the establishment of a hospital on the cottage plan, to be located outside the city. Each cottage is to accommodate about six or eight patients and to be limited to one disease.

THE OPPOSITION PARTY to the Pure Food and Dairy Laws have called attention to the fees paid and the commission during the past year, which they quote as follows: Attorneys \$17,023.09; chemists \$9,287.58.

A FIFTY-THREE year old inmate of the City Infirmary died last week while at dinner as a result of a piece of meat lodging in his trachea.

THE FOLLOWING INTERNES have been appointed for the Cincinnati Hospital for the coming year: W. Hall, L. F. Palmer, Allan Ramsey, Chas. H. Williamson, Dana E. Robinson, Fred Harpold, George C. Shafer, Arthur Freericks, Frank Scheerer, Lewis A. Maloney and Chas. Meyers.

THE CINCINNATI COLLEGE of Medicine and Surgery opened a bacteriologic course for practitioners February 9.

A COMMITTEE OF DRUGGISTS from throughout the State have visited this city during the past week and solicited the aid of the medical profession in securing an amendment to the present Pure Food and Dairy law, but they met with poor success, as the physicians feel that the law is a good one and should stand, they being in probably a better position than any other class of men to appreciate the urgent necessity for the rigid enforcement of laws to prevent adulteration.

THE ANNUAL REPORT of the Children's Hospital shows 62 admissions in the medical ward, 126 in the surgical, 47 in the ophthalmic, and 16 in the dental; total 151. Mortality: Medical 3; surgical 2; ophthalmic and aural 1.

THE HYGEIA MEDICAL COLLEGE have presented a petition to Governor Bushnell asking for recognition on the Board of Medical Examiners. This is the school whose graduates Dr. Prendergast, the Health Officer, has refused to register, and the coroner in several instances has refused to recognize death certificates signed by them and has criticised their treatment.

DR. B. F. LYLE has been appointed physician to the Branch Hospital or "Pest House," vice Dr. Geo. B. Twitchell, resigned.

Philadelphia Notes.

THE MUNICIPAL HOSPITAL.—The annual report of Dr. Wm. M. Welch, physician in charge of the Municipal Hospital

(where contagious diseases only are treated) has just been submitted to the Board of Health. The number of admissions during 1895, exceeds that of any preceding year since the epidemic of smallpox in 1871-72. The increase is attributed to the recognition by the community of the fact that the health not only of the public but also of individuals is better protected by isolation in a hospital of every case of contagious disease of a dangerous character. Scarletina and diphtheria have furnished by far the largest proportion of the cases admitted to the hospital during the last few years. The large increase in the number of patients, however, appears to be mainly due to diphtheria, the number of admissions for this disease during the last two years being greater than that of the aggregate of all other diseases. The diphtheria pavilion erected two years ago, was, during the past year, several times filled to its utmost capacity, and at the present time it is so crowded as to require two patients to occupy the same bed in more than one instance. Enlargement of this ward is urged as a necessity. Antitoxin was used in 302 cases under Dr. Welch's supervision, during the past year; 85 of these patients died making the death rate 28.14 per cent. Of the diphtheria patients who did not receive antitoxin the death rate was only 25.99 per cent. The total number of cases of diphtheria was 757.

INTRA-CRANIAL TUMORS.—The special meeting of the College of Physicians was held February 19, for the discussion of the subject of Intra-cranial Tumors, Drs. S. Weir Mitchell, W. W. Keen, Wm. F. Norris and Charles K. Mills took part in the discussion.

DR. WM. THOMSON, Professor of Ophthalmology at Jefferson College, has been chosen by the Managers of Wills Eye Hospital to fill the vacancy in the staff caused by the death of Dr. H. Earnest Goodman. Dr. Thomson was originally elected a surgeon to the Wills Hospital in 1870, but in 1877, in order to enable him to devote his attention to his clinic at the Jefferson Hospital, he was made Emeritus surgeon, and he has held this position until the present time, making twenty-six years of continuous efficient connection with the institution where he now resumes active duty upon the medical staff.

A PHYSICIANS AND SURGEONS' office building, ten stories high to be erected in the neighborhood of 18th and Chestnut Streets, has been planned and will probably be built during the coming year.

FILTRATION OF THE WATER SUPPLY is under consideration by City Councils and is so strongly supported by public opinion that an appropriation will doubtless be made for the purpose.

A CASE OF FILARIA SANGUINIS HOMINIS. Dr. Frederick P. Henry, at the last meeting of the County Medical Society, reported the finding of this parasite in the blood of a patient at the Woman's Hospital, who had developed chyluria after labor. The patient was a white woman, who has lived in Philadelphia not quite a year. Microscopic slides were shown at the meeting, demonstrating the presence of the living embryos. Dr. Henry thought that the parasite had been originally acquired during residence in the south, and that a rupture of a lymph-vessel during the strain of labor had led to the chyluria, and this suggested examination of the blood. He referred to a former case of chyluria, which he had reported to the Society, that of a Cuban, and who had since died. At the autopsy, the abdominal lymph-channels were found distended; but neither embryonic nor mature filariae could be detected, although he still held that the case was of this character. Cases of chyluria in which the parasite had not been discovered were also reported by Drs. Tyson, Wilson and Cohen, and it was stated that the above case of Dr. Henry's, which represented the nocturnal form of filarial manifestation, was the first one reported in this city, in which the parasite had been demonstrated.

THE AMERICAN SOCIETY of Superintendents of Training Schools for Nurses have just concluded a very successful and

profitable meeting in this city at which a number of interesting and practical papers were read and discussed: the annual dinner was held at the Colonnade Hotel. The officers elected were: President, Miss M. A. Nutting, of Johns Hopkins Hospital; Vice President, Miss M. E. P. Davis, University of Pennsylvania Hospital; Secretary, Miss Dock, Cook County Hospital; Treasurer, Miss L. Drown, Boston City Hospital. Next place of meeting, Baltimore during the second week in February, 1897.

DR. DANIEL G. BRINTON is delivering a course of eight lectures, free to the public, at the Academy of Natural Sciences, on Friday afternoon, on the Scientific Study of Man. The lectures are well illustrated and are popular in style, and attract large audiences. His topics are: The Universe and Man from the Standpoint of Science; Man's Position in the Chain of Animal Life; The Origin of Man; Races and Varieties of Man; Geographic Distribution of Man; Man as a Wild and as a Domesticated Animal; The Metaphysical in Man; The Man of the Present and the Future.

THE RÖNTGEN RAYS IN SURGERY. At the meeting of the College of Physicians March 4, Drs. E. P. Davis and W. W. Keen gave a demonstration of the clinical use of Röntgen's Rays, and Prof. W. F. Magie, Ph.D., explained the technical method and physical character of the phenomena. A patient was presented who had received a gunshot wound in his forearm fifteen years ago, by a 32 caliber bullet. He applied for treatment at the Pennsylvania Hospital, where he was under the treatment of Dr. Agnew, who could not find the ball nor could Dr. Hart, who was resident surgeon at the time. The patient was a policeman but was obliged to retire from active duties on account of the wound. Lately he has had a good deal of pain in the extremity, interfering very much with the use of his hand. Dr. Hart had a photograph taken by the Röntgen process and in the negative exhibited the ball was seen to be located near the styloid process of the ulna, making the indication for operation very definite. A case of united fracture of the bones of the forearm in a young man, was presented and a photograph made at the meeting, and the negative was immediately developed, beautifully showing the lines of fracture in both the radius and ulna, and the deformity due to deflection of the ulna.

Dr. Davis, editor of the *American Journal of Medical Sciences* stated that a number of experiments had been made by direction of that journal and that the demonstration on this evening was the outcome of that work. They had found by experiments upon the cadaver that foreign bodies particularly those consisting of metal or of glass, when introduced into the tissues, could be located with tolerable certainty, and that a diagnosis between an abscess and a solid tumor could be made. Experiments made in the bacteriologic laboratory showed that the new rays have no influence in retarding the growth of bacilli. In a pregnant woman he had succeeded in obtaining a shadow picture of the fetal head, or that part of it lying above the brim of the pelvis. He thought that this method might prove useful in the diagnosis of pregnancy. Professor Magie presented the physical aspect of the subject and explained the apparatus which consisted of a dozen storage cells, a Ruhmkorff coil, a Crooke's tube and the ordinary plate holder containing a sensitive photographic glass-plate which was entirely enclosed. The X rays proceed in straight lines from the Crooke's tube, and are neither reflected nor refracted: the object to be examined is placed between the tube and the plate, during exposure to the rays. Professor Magie showed an instrument consisting of a telescopic tube, at the large end of which was placed a diaphragm of opaque material saturated with a compound salt of platinum, which has the property of becoming luminous under the influence of the Röntgen's rays. With this instrument, the shadows were made visible, which in the other process were fixed by photography. As regards

the nature of the phenomena, he said without hesitation that the X rays are not the ultra-violet rays of the spectrum, because they can not be reflected nor refracted. He could not accept the view that they are the ordinary cathode rays although Goldstein of Berlin holds that there are two species, of cathode rays, one of which can be deflected by a magnet and the other not. It is possible that the latter are identical with Röntgen's rays. Another theory is that they are due to molecules shot off from the negative pole. There is another view, which receives support from a recent paper by Woodman in which he discusses the electro-magnetic theory of light. Röntgen has proposed the hypothesis that the rays are due to longitudinal vibrations of ethereal molecules which, if found to be true will be one of the great discoveries of the century and will place its author on a par with Faraday.

Dr. Keen approved the name suggested by Dr. Cantell of skiagraphy for the Röntgen process and "skiagraphs" for the photographic results. The applications to surgery are valuable but in a limited range. Where bony walls intervened, like the pelvis or the skull, not much information could be gained, but for deformities of the bones, tumors, discolorations, fractures, it may be useful in discovering any abnormality. After the dressings are applied, you could see without disturbing the dressings, if the fracture has been properly adjusted or not. While we may not determine the existence of a stone in the bladder, on account of the surrounding pelvic bones, we may be able to detect a stone in the kidney, but a stone in the gall-bladder will scarcely be seen in this way. Needles, or pieces of glass, imbedded in the tissues of the hand for instance are readily located by this means which is a valuable aid in diagnosis in these common injuries.

THE PUBLIC SERVICES.

Marine-Hospital Changes. Official list of changes of station, and duties of Medical Officers of the U. S. Marine-Hospital Service, for the ten days ended February 29, 1896.

- P. A. Surgeon G. T. Vaughan, leave of absence for seven days granted Feb. 17, 1896, revoked Feb. 27, 1896.
- P. A. Surgeon G. M. Guiteras, directed to proceed on March 25, 1896, from Gulf Quarantine Station to Key West, Fla., and assume command of Service, Feb. 27, 1896.
- P. A. Surgeon A. C. Smith, to proceed from Memphis, Tenn., to Gulf Quarantine for duty, Feb. 25, 1896.
- P. A. Surgeon G. B. Young, when relieved at Key West, Fla., to proceed to Memphis, Tenn., and assume command of Service, Feb. 27, 1896.
- Asst. Surgeon H. W. Wickes, to assume temporary command of Service at Memphis, Tenn. Upon being relieved to rejoin station at New Orleans, La., Feb. 24, 1896.

Change of Address.

- Brenner, F. T., from 514 Maine St. to 700 Maine St., Quincy, Ill.
- Hall, W. W., from Thomasville, Ga., to Springfield, Ohio; Hildreth, M. L., Sioux City, Iowa, to Lyons, Neb.
- Sims, S. N., from St. Joseph to 310½ Hazel St., Danville, Ill.; Sutton, E. M., from Canton to Rooms 11 and 12, Masonic Temple, Peoria, Ill.
- Wenton, H. N., from 922 Sutler St. to 406 Sutler St., San Francisco, Cal.

LETTERS RECEIVED.

- Allport, Frank, Minneapolis, Minn.; Alexander, L. C., (Miss) Philadelphia, Pa.; Alta Pharmacal Co., St. Louis, Mo.

The Journal of the American Medical Association

VOL. XXVI.

CHICAGO, ILL., MARCH 28, 1896.

No. 13.

ADDRESS.

CLOSING EXERCISES OF THE SESSION 1895-96. ARMY MEDICAL SCHOOL.

INCLUDING AN ADDRESS
BY JOHN H. BRINTON, M.D.
PHILADELPHIA.

The closing exercises of the second session of the Army Medical School were held in the hall of the Library of the Surgeon-General's Office, Washington, D. C., on Friday, March 13, at 3 P.M. Card invitations had been sent out and by the hour mentioned the medical profession of the city of Washington was well represented in the audience with many War Department officials and a large contingent of ladies. The library for the time being, put off its air of silent study and assumed quite a gay appearance, as the sunbeams through the west windows lit up the colors of the flags which draped the walls and made brighter the bright eyes and interested faces which met the gaze of Colonel Charles H. Alden, President of the Faculty as he arose to open the proceedings.

It is not necessary, he said, to go into any extended account of the school; but as some might be present who would like to know something of the work it is doing, he would state briefly that the school is a post-graduate institution designed to teach the young medical officer on his entrance into the service, and before he goes out to his first duty, branches that are of especial importance to him as an army medical officer. These are branches either not taught in the general medical school from which he has graduated, or whose application to army service needs to be brought out. Further, its purpose is to familiarize him as far as practicable with the new conditions under which he is about to be placed, and the duties he will be called upon to perform. The school is open also to medical officers of older date who may be able to avail themselves of its privileges.

Established in June, 1893, by order of the Secretary of War on the recommendation of Surgeon-General Sternberg, its first session was held from November, 1893 to March, 1894. No session was held in the winter of 1894-95, as the number of medical officers had been reduced, and there were no new assistants to enter the school. The laboratories, chemic and bacteriologic, were open, however, and several medical officers availed themselves of the instruction given therein. The present session began Nov. 18, 1895, and lasted four months.

The teachers of the school are medical officers of the army stationed in Washington and vicinity, who give instruction during the session in addition to performing the regular duties to which they are assigned. During the session now closing, in addition to the five recently appointed medical officers who entered the school immediately after passing the examination

for admission and receiving their appointments in November, 1895, four older assistants have been in attendance, one having taken leave and come to Washington for the purpose, the others, being stationed in Washington and vicinity, have taken such part of the course, especially the laboratory work, as their regular duties admitted. Two medical officers of the District of Columbia National Guard and one from the Massachusetts Volunteer militia have been present during a part of the time and received instruction in some of the subjects treated, especially the lectures and hospital corps drill.

To carry out the purposes of the school, the following courses of instruction were laid down in the order establishing it, and have been carried out during the past session: On the duties of army medical officers; on military surgery; military medicine; military hygiene; sanitary chemistry; clinical and sanitary microscopy, including bacteriology (chemistry and microscopy being laboratory courses); hospital corps drill and first aid. It has been the object of the lecturer on the duties of medical officers to familiarize the student officer with his future official duties so far as practicable; to give him sound notions as to military discipline and his true relations to the commanding officer and others in the military service, as to his proper position as a sanitary officer, the obligations involved in the care of his patients, and correct ideas as to his responsibility for the care of public property entrusted to his charge. He was given practical instruction in the examination of recruits, in making sanitary inspections of posts, in preparing certificates of disability for discharge, and other important papers. The course in military surgery included the care of wounded on the battlefield, their transportation from the scene of action, hospital administration, an account of modern weapons, the wounds they cause and their appropriate treatment, according to the latest and most approved methods. The lectures on military medicine treated of diseases due to the aggregation of men in armies, camps and garrisons, to exposure to climatic extremes, and to infectious diseases and the mode of prevention and treatment. The course on military hygiene included the subjects of pure air, water and food, their impurities and the source of them, the dangers resulting from their contamination, and the methods of detecting and remedying the evils resulting therefrom. The important subjects of the disposal of sewage, of climatology, quarantine and public health, were also treated of.

An examination of the order of daily duties will show that the lecture courses consumed a brief portion of each day, being held from 3 to 4 P.M. A larger part of the time of the students was passed in the pathologic and chemic laboratories. The instruction in the former, lasting from 9 to 12 daily, was of a very important character, covering the study of the forms and life history of the more important

disease-producing bacteria, so as to enable the medical officer to recognize the existence of the germs of infectious diseases and to apply the most approved methods of destruction or exclusion. When we consider the number of diseases now recognized to be due to specific germs, their widespread diffusion and their ravages, one disease alone, tuberculosis, causing more deaths than any known disorder; when we consider that an accurate knowledge of the germs causing suppuration and septic infection has alone made possible the triumphs of modern surgery, we will see that the prominence given to this laboratory work is amply justified by its importance. The course on sanitary chemistry lasted from 1 to 3 P.M. each day, and included the analysis of air, water and food, the detection and estimation of their impurities and adulterations, the detection of poisons, and the study of the animal fluids. It is designed to fit the medical officer to become the sanitary expert and inspector of the command to which he may be in future attached. The instructor in hospital corps drill, after giving the students a preliminary training in the school of the soldier so as to improve his military bearing, took up litter and ambulance drill, first practically with the students as litter bearers and afterward as instructors of the men in the hospital corps company at Washington Barracks. The methods of first aid were also taught, and finally the young officers were given instruction in riding at Fort Myer, Va., through the kindness of the commanding officer and one of his lieutenants.

In addition to the regular courses referred to, a short but very important course on military law was delivered by Lieut.-Colonel G. B. Davis, Deputy Judge Advocate, Professor of Military Law, U. S. Military Academy, West Point, N. Y.; Dr. Robert Fletcher, F.R.C.S., principal Assistant Librarian, Surgeon-General's Office, delivered an instructive and interesting lecture on the Army Medical Library; and Professor Stiles of the Department of Agriculture repeated his valuable instruction on Parasites in Man, given on a former occasion. The class has received clinical instruction in mental diseases at the Government Hospital for the Insane, Washington, D. C., through the kindness of the Superintendent, Dr. W. W. Godding; and a practical course in operative surgery has been given by the Professor of Military Surgery.

This brief summary will give an idea, though a very imperfect one, of the subjects treated, and will show that the time of the student officer has been fully occupied.

It has been a source of great satisfaction to the Faculty of the school, and I am sure it must be to the far-seeing officer at whose instance it was established, to find that the young medical officers who have gone out from the school have acquitted themselves most creditably, and in such a manner as to show that the training here gained has been a positive advantage to them, and not only so, but that these young officers have become teachers in turn, and have communicated the instruction given them in bacteriologic and chemie manipulations to their comrades who have been less fortunate than themselves in opportunity for instruction. There is every reason to believe that the members of the class now leaving the school will acquit themselves with equal credit. They have, as student officers, been as a rule prompt in attendance and attention to their duties, and displayed commen-

dable diligence and an intelligent interest in their work. They have the warmest wishes of the Faculty for their future welfare and success.

Colonel Alden then introduced Dr. John H. Brinton, Professor of Surgery, Jefferson Medical College, Philadelphia. Dr. Brinton, during the progress of our civil war, had been requested to deliver an address at the inauguration of a proposed army medical school. All was ready in 1863; but the projected school did not receive final official approbation and failed to become a reality. Not until thirty years later did it become established and now he is about to address this school. Speaking of the failure of the effort to establish it during the war, Dr. Brinton said:

DR. BRINTON'S ADDRESS.

The disappointment was great to those who had anticipated much from the proposed school and who believed that, once established, its influence would be most happy and far-reaching. No one felt this regret more deeply than the speaker, but at the same time ever with the earnest hope and firm conviction that the establishment of an Army Medical School was but a matter of time; that sooner or later its necessity would be recognized, and that the day would come when the Medical Department of the Army of the United States would stand, as regards medical education, fully abreast with the medical services of nations beyond the seas.

And it has come. How do you know? By the wise direction of the Secretary of War, at the recommendation of a Surgeon-General, who combines true military zeal with the highest scientific professional attainments. These efforts of the chief of the department to elevate and maintain the professional status of the medical corps have been nobly seconded by the President and Faculty of the Army Medical School. There is no more difficult and responsible post than that of teacher, and our country is most happy in commanding in this school the services of a faculty who to past experiences in active warfare, add the judicial influences of thought and study. That under such impulses the school has prospered and has assumed its true position, this public gathering, this official presence bear ample witness.

Through personal kindness, and I fear unwise partiality, I have been asked to say to you, members of the graduating class, a few words. Let me at once confess that in accepting this flattering and delicate duty, I have been influenced by the recollection of many kindnesses I have received from cherished friends in the old army and by the desire, almost craving, to renew with them, or their successors, my past associations.

In the presence of such an audience I scarce know how to choose my words, yet it must not be forgotten that we come here to assist in the closing exercises of a session and to commemorate the passing out of you graduates into the active duties of your calling. Your functions as military medical officers will be discharged under circumstances widely differing from those of your predecessors, and these conditions have doubtless been bettered to some extent by the lessons of a past experience. Are they not in some degree due to the practical and varied teaching of the great war through which our nation passed thirty years ago? What has been for the Medical Department of the Army the professional output of the war of 1861? Apart from the vast and wide-spread individual experiences, the

example and memory of which can never die, we have the Army Medical Museum, its catalogues and literature, and the circulars, medical and surgical, of the Surgeon-General's office; above all we have the massive volumes of the Medical and Surgical History of the War, known, read and studied the world over.

I think, too, that the library of the Surgeon-General's office may fairly be regarded as one of the secondary results of the war, and from the library under the supervision of its accomplished Director, Dr. Billings, and its learned Librarian, that courtly man of letters, Dr. Fletcher, sprung its inestimable catalogue and I may venture to add the *Index Medicus*, the value of which to medical writers now and in all time can not be overrated. With all of these productions of the war you are conversant. I trust, nevertheless, that it will not be tedious to you if I briefly refer to the small beginnings of one (the Museum) and consider in a few words its influence upon the army surgeon and his work.

The official history of the Army Medical Museum has long since been published and its catalogue prepared under the direction of the Surgeon-General in 1866, is familiar to you all. It is not, however, generally known that in January, 1863, a preliminary catalogue was issued, setting forth the character of 1,349 objects which had been collected for the Museum in the five months since its establishment in August, 1862. Of these, 985 were surgical, 106 medical, and 133 were missiles. The curator of the Museum at that time stated in his prefatory report that the catalogue was offered simply as a numerical list of objects in the Museum, and that no attempt had been made to classify or describe them; that work must be deferred for the future when it would demand volumes.

On the title page of the original copy of this catalogue is the manuscript entry: "Many specimens from battle-field sources are in this catalogue credited to medical officers in the field who were opposed to the collection of specimens. By this means opponents often become later enthusiastic contributors to the Museum." This undoubtedly was a pious fraud, harmless, but useful.

The proposed establishment of the Museum was announced in Circular No. 2, Surgeon-General's Office, May 21, 1862. Its title at first was the "Military Medical Museum," but in the catalogue published Jan. 1, 1863, the name "Army Medical Museum" appears, and since that time the collection has been so designated officially. When its foundation was decided upon circular letters were sent to medical officers of the regular and volunteer corps and to all medical officers in charge of field and permanent hospitals setting forth the object of the Museum and inviting their earnest and intelligent coöperation. It was not intended to impose upon them the labor of preparation, but only to command their services in saving and forwarding to the Surgeon-General's office as many specimens as could be procured and saved from the vast number of daily casualties in the Army. By many of the most intelligent officers these orders were received and executed in good faith; by others they were neglected, and not a few looked upon the project with derision and stigmatized the future Museum as "a collection of old bones." At first, too, there was some natural aversion on the part of the wounded soldiers and their friends. The topic was a ghastly one, yet often a streak of humor would appear. I can recollect one instance of a very rare and carefully studied

case of leg injury. The patient died and was buried in soldier fashion. His bosom friends sat up and watched to prevent the much-feared desecration. The nefarious collector came. So great was his earnestness, so deep his sympathy, so moving his eloquence, so unanswerable his argument that patriotic bones rest better in Government cases than in a Virginia trench, that the stony hearts of the watchers were softened. Slowly and mournfully the former comrades marched to the burial spot. The leg was exhumed, the bone taken out and carefully inspected by the mourners, the chief of whom remarked, as the procession sadly moved campward, "After all, John would rather be of some use to the very end." *Quis custodiet custodes?*

It was no easy matter to popularize, if one may use the expression, the surrender to the Surgeon-General's office human specimens. It was only when medical officers in field and hospital felt that the Medical Department was really in earnest, that a great work was in progress that objects of the highest interest to military surgery and to the wounded of the future, were in contemplation, then only was the work of preservation and collection efficiently carried on. To obtain specimens accruing after action on the field, and in field, division and corps hospitals, the curator and his assistants were constantly sent to the front. The find, the aggregate of the operating tables roughly cleaned, were packed in barrels and forwarded to Washington. By General Order No. 116, May 22, 1863, Headquarters Military District of Washington, the schoolhouse on H street, between Thirteenth and Fourteenth, owned by Mr. Corcoran, had been taken possession of by the government and turned over to the Medical Department for the use of the Army Museum. This edifice and the outbuildings attached were immediately fitted up by order of the Acting Surgeon-General as a museum and working laboratory, and on Sept. 1, 1863, the Secretary of War authorized the transfer of the specimens from the room of the Surgeon-General's office to the newly selected Museum. The beginning of the Museum in August, 1862, was very modest, consisting of three dried and varnished specimens placed on the little shelf above the ink stand on the desk of the recently appointed curator. These were duly inspected and admired by the office officials and for a while, as a novelty, they had numerous visitors from the surgeons on duty in and around the city. "How is the Museum?" was the joking question of the day, and I doubt if anyone seriously believed that from this apparently ridiculous beginning would arise the magnificent Military Medical Museum which I believe influences and will influence to no slight degree the future of American military surgery.

But a start had been made, professional zeal had been excited, and the idea got around that perhaps after all there was something in the notion that even "dry bones may live." Soon kegs and boxes from the field and general hospitals began to arrive. The preparer of the bones, Friederich Schaffhirt, who under the unpretentious name of hospital steward, had been procured from the University of Pennsylvania, where he had long labored as an assistant to the immortal Leidy, was overworked. And here let me pay my tribute of respect to the memory of one who at this time did so much for the Museum, and without whom, perhaps, the collection had not then taken shape.

When specimens were gathered at the front their

preservation and transportation were no easy matter. The former involved the use of alcohol or whisky, at all times, within army lines, a fluid most apt to suffer mysterious leakage. "Tapping the Admiral" is a well-known nautical phrase, and it is said that in 1848 or 1849 when certain bodies of Russian Cossacks camped near the museum of Professor Hyrtl the alcoholic exosmosis from his jars was difficult, or perhaps easy, to explain. With us, indeed, it often happened that whisky on its way to the front, even though in barrels marked benzine or petroleum, was sure to leak, and kegs reaching their destination would show ingeniously plugged gimlet holes. How and why this was done I learned only the other day from a tottering veteran who had once been on duty on the line of the Aquia Creek Railroad. His explanation of the gimlet hole, and inserted pipestem seemed credible, and the twinkle of his eye, suggested the motto: "Experto Crede." But the stimulant had other than preservative qualities and the Museum was well supplied with it in this wise: In war times, in Washington the provost marshal's department confiscated all wines and liquors brought to the city save on official permit, and all confiscated and condemned packages were turned over to the Museum for the distillation of pure alcohol, which was carried on in a lot adjoining the laboratory. So many a basket of champagne and box of Rhine wine and dozen of liqueurs found their way into Schafhirt's insatiate still. Now and then a keg of cherry brandy or the like, peculiarly soothing to military nerves, was saved and served as a ready passport for the Museum Messenger in search of pathologic specimens. In fact, in most commands he was a welcome guest and a dispatch announcing his coming was honored as if it were the order of a secretary of war. Ah, I can see now the honest face of Sergeant K., who, with the compliments of Captain M. of the 105th Cavalry, had ridden down with two or three led animals to serve as escort and guide. How carefully the kegs were lashed on the pack saddle of the old roan, "and this keg is for the officers' mess, and this for the men's, and sure, sor, we must be riding now, if ye would reach camp and be getting something warm before taps."

Occasionally it would happen that a specimen would be contributed to the Museum by its former owner. No. 1335, resulting from a leg crushed by a twelve-pound shot at Gettysburg, and for which thigh amputation was performed, was forwarded to the Museum in an extemporized coffin on which was tacked a visiting card "with the compliments of Major General D. E. S., United States Volunteers." But all were not so complaisant. On one occasion a man from the ranks demanded the return of a limb, an arm, I think. He was informed that the member in question could not be given up. "But it is mine," said he, "part of myself," earnestly enforcing his claim, and his demand to the lay mind seemed reasonable. Yet to surrender a specimen was very much like yielding a principle. "Stop," said the quick-witted young assistant curator to the claimant, "for how long have you enlisted?" "For three years or the war," "Then," replied the official "the contract is not yet terminated, come back at the end of the war or at the expiration of your three years' service and you can have your bone. In the meantime one detachment of you is stationed in this Museum on government duty, the other wherever you may be ordered. Such is the opinion of the Attorney General." The reply and its

reason seemed conclusive, and the bone remained in its place.

But enough of old-time anecdote. Let us consider the Museum, not as a collection of curiosities or objects of historic interest, but rather as a teaching school of the first grade. For in it, I believe that lessons of much value in military medicine and surgery may be learned, which nowhere else in this country can be so fully illustrated. As an adjuvant to the Army School its influence must be potent, for among its contents can be found exhibitions of pathologic conditions of most of the diseases and injuries met with in the warfare of the past. Look at the jars in which are shown the lesions which marked the so-called typho-malarial fevers. How mutely eloquent they are, how much they tell you of the soldiers of our great war, how they lived, how they suffered, how and why they died. Study these preparations in the light of our recent knowledge of sepsis and bacteriology, and we can almost see the country through which these men marched, and we fancy we can inhale the air they breathed, and taste the water which they drank. Indeed, and we can imagine every noxious influence by which they were surrounded. Then we cease to wonder that so many perished; we rather marvel that so many lived through it all. The thoughtful student of to-day will ask himself how these unhappy conditions can be minimized or warded off hereafter, and the professors in your school will tell you and impart to you a knowledge which we never had. Look at that gunshot splintering near the knee condemned at first sight because of the joint fissure; then amputation was the only remedy. Now, thanks to Sir Joseph Lister and the outcome of his teachings, wrought out by busy brains, and by none more patiently and successfully than by him who heads your corps, the limb fares otherwise. Salvation, not destruction, is the motto to-day. Compare the small-arm missiles of the past with those of the present time, the leaden bullet with the jacketed projectile. Consider their relative velocities, ranges, penetrative powers and modes of flight, and almost at a glance their wound tracks will be understood. The Museum makes easy of comprehension the phenomena of the modern gunshot injuries. The past helps us to judge the present, and almost foresee the future. These truths, too, are easily learned, for they are taught as objective lessons. In the quaint language of three centuries ago: "For speech, how perspicuous and eloquent soever it be, it can not so vividly express anything as that which is subjected to the faithful eyes and hands." As for the military surgery of the future, no one, however great his experience, may speak with certainty; he can but forecast, basing his guess upon deductions from the relics of past wars. These are even better than books since they permit, indeed invite, an individual judgment. Nowadays the teachings of books in our profession soon merge. The ink of an edition is scarce dried ere its doctrines become obsolete. New modes of study are found out and even as I write, the magic subtlety of Röntgen's ray would seem to banish touch and substitute the sense of vision. What next?

In an elaborate address by one who has shed much luster on American surgery, Professor Senn, the conservative character of the surgery of future battle-fields is strongly dwelt on. In his opinion the dangers of hemorrhage and infection will be lessened by improved hemostasis and by the enforcement of more thorough

asepsis and antisepsis. It is quite probable that the hemorrhage caused by the modern projectile will be greater than that produced by the old-fashioned round or elongated Minie ball, as it was called. The greater velocity of the former and its increased axial rotation will give to the resulting wound more of an incised nature. However, as it will cause less bruising and laceration, the risk of secondary bleeding will be diminished. To prevent the infection of battle wounds doubtless every immediate precaution will be taken, but I fancy that the fighting line must be much as in the past, and despite the soldiers' antiseptic package that the real, effective surgical antisepsis will be exerted at the field hospitals in the rear. Here the wounds will be carefully examined, their diagnosis arrived at, the prognosis established and the operations, treatment and dressings deliberately and definitely entered upon to be persistently carried out. Many of the sad results which have followed the injuries of war must be avoided in times to come. This humane tendency will grow greater with fresh knowledge and with that increased and more efficient skill which knowledge brings, and so the condition of the wounded will be ameliorated. Think what it was in 1535 when Paré writes of the campaign of the French against the army of the German Emperor at Turin: "We entered the throng in the Citie and passed over the dead bodies and some of which were not yet dead. We heard the cry under our horses' feet which made my heart relent to hear them, and probably I repented to have forsaken Paris to see so pitiful a spectacle. Being in the Citie I entered a stable thinking to lodge my own and my man's horse, where I found four dead soldiers and three which were leaning against the wall, their faces wholly disfigured and neither saw nor heard nor spoke, and their clothes did yet flame with gun powder which had burned them. Beholding them with pity, then happened to come an ould soldier who asked me if there were any possible means to cure them. I told him no. He presently approached to them and cut their throats without anger. Seeing this great cruelty I told him he was a wicked man. He answered me that he prayed to God that whenever he should be in such a case that he might find some one that would do as much to him that he might not miserably languish."

And here at Turin, Paré obtained by gifts and presents from a surgeon famed above all others for curing gunshot wounds, the recipe for his excellent balsam. He thus gives it: "Boil young whelps newly pupped, in oil of lillies, prepared earth worms with turpentine of Venice," and adds, "then was I joyful and my heart made glad that I had understood his remedy." Great stress in those old days was laid upon the composition of these "vulnaria," or wound powders, ointments and balsams from which much healing value was expected. I would have you note that in the decoctions of worms, puppies and geese there was a plentiful admixture of turpentine, aloes and myrrh, poppy, hyoscyamus and gentian, tolu, red wine and oil of juniper, and here we have articles of real therapeutic and almost antiseptic value. Such were the accompaniments of war three centuries ago; such was the surgery at the hands of one of the princes of our craft who, conferring great gifts on humanity, was destined to professional immortality. Think of the import of this sentence regarding amputations: "The ends of the vessels lying hid in the flesh must be drawn forth. To conclude, when you have so drawn

them forth, bind them with a strong double thread."

Quite recently I was told by an aged and venerable friend this, which may not be irrelevant: Fifty years since in the Philadelphia library was a small medical folio on the side of which was stamped the royal arms of England. It had been bequeathed to the library by a book collector, but a visitor from London recognized it as the former property of the British Museum, from which it had been stolen, and it was returned. In it was the following: "Take three blind puppies, put them in a mortar and pound them well, add" so and so, what at this long interval my informant had forgotten. In a marginal manuscript note, identified as the handwriting of King Charles I., were these words: "Tried this on the Prince. It did his business."

As one with the experience of later years walks through the National Military Museum, he can not fail to be impressed with the lessons which confront him on every side. He feels that the mutilating amputations and resections once so common must in future wars be greatly diminished in proportion. The new projectiles are far more humane in their effect upon the bony system. They penetrate rather than crush, and shattered wounds even when they occur will be, thanks to antisepsis, far more amenable to conservative treatment than of old. A limb may be saved and a joint preserved when once it would have gone as a matter of course, and our attempts at preservation now cease to be experimental, and have become recognized treatment. Professional opinion has changed, old judgments are reversed, new lines of study opened, new conclusions arrived at. These changes have been gradual but steadily progressive. In the aggregate they amount to revolution. I have often wondered what would be the impression of those of our brethren who have gone to rest twenty, fifteen, ten years ago, if they could now arise from their dust and view the existing state of the art once theirs. They would indeed find old manners changed, old customs gone, and realize that the greatest savant of yesterday would be the merest tyro of to-day.

Following out this idea of incessant and bewildering change, let me ask you to reflect for one moment on the marvels which have marked the onward strides of abdominal surgery, for in this direction perhaps first and most decisively has antisepsis achieved her victories, and these successes have been reached through the practice of an aggressive surgical interference, guarded by a strict precautionary antisepsis. Years ago, and not so many either, the unfortunate recipient of a penetrating wound of the abdomen was looked upon as little less than a dead man, his way was through that portal which those who enter leave all hope behind. Look at these well-weighed figures of our Otis in the Surgical History of the Rebellion, 3,717 cases, 3,031 deaths, a mortality of 87.2 per cent. In the British army of the Crimea the death rate was over 92 per cent. and in the French army of the East this rate was almost the same; in the German army at the siege of Paris, the rate was 94 per cent., and in the French army at Sedan an equal ratio. It is, of course, impossible now in times of peace to make comparison with the results above quoted, but I feel assured that hereafter when comparisons may be practicable the finding will be very different, for have we not laparotomy and all of the abdominal technique, washing and drainage, intestinal anastomosis, and the ectomies? From the practice spring fresh confidence

and firm convictions and a new born courage, the offspring of these convictions. We know how great a success has crowned the endeavors of civil surgeons and we may rightly conclude that when the time comes a like result will be attained in military practice, for there must be a new surgery of the battlefield. How different was it in pre-antiseptic days. I can recall memories far too sad to dwell upon. I can almost see before me the phantoms of the many who have perished from just such injuries as those alluded to. With every wish to help them and with every known effort so little in reality was done. The best knowledge of that day could not even accomplish a respectable diagnosis; the treatment was expectancy with folded hands. The quoted figures speak for the results. The idea of searching for a bullet in a penetrating abdominal wound was not entertained. In the solitary recorded instance in which a world-famed operator asked "why not open the cavity and search for the ball," the very question was regarded as an evidence of genius gone astray and the suggestion was not even considered. Yet to-day the medical student in his second year could rightly formulate the treatment, now laparotomy, hemostasis, packing, drainage.

So, too, in regard to chest injuries. The experience of the last few years has shown that portions of the ribs and chest walls can be raised or even removed without injurious consequences. Estlander's operation is familiar to every surgeon and it can not be doubted that this operation may be so modified as to permit access to the pleura and the subjacent lung. I believe that deeply placed foreign substances will be traced, detected and removed and that hidden abscesses may be aspirated and emptied. Indeed the surgery of the chest is in its infancy, and when developed must prove life-saving. Instances of gunshot wounds of the chest occur to me, in which postmortem examinations revealed the presence of bullets which I am sure could have been found and removed by the methods of thorectomy alluded to. The pity was that we did not know; you do.
